SUPPLEMENT

TO THE

ENCYCLOPÆDIA,

OR

DICTIONARY

OF

ARTS, SCIENCES,

AND

MISCELLANEOUS LITERATURE.

IN THREE VOLUMES.

ILLUSTRATED WITH COPPERPLATES.

NON IGNORO QUÆ BONA SINT, FIERI MELIORA POSSE DOCTRINA, ET QUÆ NON OPTIMA, ALIQUO MODO ACUI TAMEN, ET CORRIGI POSSE.—*CICERO.*

VOL. I.

A———ELE

Philadelphia:

PRINTED BY BUDD AND BARTRAM,

FOR THOMAS DOBSON, AT THE STONE HOUSE,

N° 41, SOUTH SECOND STREET.

1803.

ADVERTISEMENT

By the Rev. Dr GLEIG *to the* EDINBURGH EDITION.

It would ill become me to dismiss these Volumes from my hands without acknowledging that, from many of the most valuable disquisitions which they contain, I can claim no other merit than that of having ushered them into the world.

Those who have read, and who understand, the articles in the Encyclopædia Britannica, which were furnished by Professor Robison of Edinburgh, can hardly need to be informed, that to the same eminent philosopher I am indebted for the valuable articles Arch, Astronomy, Carpentry, Centre, Dynamics, Electricity, Impulsion, Involution, *and* Evolution *of Curves*, Machinery, Magnetism, Mechanics, Percussion, Piano-*Forte*, *Centre of* Position, Temperament *in Music*, Thunder, *Musical* Trumpet, Tschirnhaus, and Watchwork, in this Supplement. Of a friend and co-adjutor, whose reputation is so well established as Dr Robison's, I am proud to say, that, while I looked up to him, during the progress of this Work, as to my master in mathematical and physical science, I found him ever ready to support, with all his abilities, those great principles of religion, morality, and social order, which I felt it my own duty to maintain.

To Thomas Thomson, M. D. of Edinburgh, a man of like principles, I am indebted for the beautiful articles Chemistry, Mineralogy, and *Vegetable*, *Animal*, and *Dyeing* Substances ; of which it is needless for me to say any thing, since the Public seems to be fully satisfied that they prove their author eminently qualified to teach the science of chemistry.

The account of the French Revolution, and of the wars which it has occasioned, has been continued in this Supplement by the same Gentlemen by whom that account was begun in the Encyclopædia ; and, owing to the cause assigned in the article, probably with the same merits and the same defects.

My thanks are due to Dr William Wright for his continued kindness in communicating much curious botanical information: and to Mr Professor Playfair of the university of Edinburgh, for lending his assistance, occasionally, in the mathematical department; and for writing one beautiful article in that science, which is noticed as his in the order of the alphabet.

In compiling this Supplement, I have made very liberal use of the most respectable literary and scientific journals, both foreign and domestic; of all the late accounts of travels and voyages of discovery, which have obtained, or seem indeed to deserve, the regard of the Public; of different and opposite works on the French revolution, and what are emphatically called *French principles;* and even of the most approved Dictionaries, scientific and biographical. From no Dictionary, however, have I taken, without acknowledgment, any articles, except such as are floating everywhere on the surface of science, and are the property, therefore, of no living author.

After all my labour and industry, which, whatever be thought of my other merits, I am conscious have been great, no man can be more sensible than myself, that the Encyclopædia Britannica, even with the addition of this Supplement, is still imperfect. It would continue to be so, were another Supplement added to this by the most learned and laborious man on earth; for perfection seems to be incompatible with the nature of works constructed on such a plan, and embracing such a variety of subjects.

No candid reader will suppose that, by expressing myself thus, I mean to censure the plan of the Encyclopædia Britannica in particular; for, to the general excellence of that plan I have elsewhere borne my testimony, which I have yet seen no reason to retract. Experience has indeed led me to think, that it is susceptible of such improvements as would enable the principal Editor to carry the work *nearer* to perfection, even with less trouble to himself; but the purchasers of the third edition and this Supplement need not regret the want of those improvements, for they are such as few would discern, who have not paid the same attention that I have done to dictionaries of arts, sciences, and literature.

Before I take leave of the reader, I must account for the omission of one or two articles (chiefly biographical) which I had given him reason to expect

pect in these volumes. It was my intention at first to introduce into the Supplement articles on every subject which had been admitted into the Encyclopædia itself; and hence in the first supplementary volume will be found biographical sketches of men whose characters, though in some respects remarkable, have very little connection with science, arts, or literature. From this part of the original plan I was soon obliged to deviate. So many applications were made to me to insert accounts of persons who, whatever may have been their private virtues, were never heard of in the republic of letters, that I was under the necessity of excluding from the second volume the lives of *all* such as had not either been themselves eminent in literature, or in some liberal art or science, or been conspicuous as the *patrons* of science, arts, and literature, in others. Hence the omission of the life referred to from AUBIGNE in the first volume, and of one or two others, to which references are made in the same way. The life of Mr James Hay Beattie of Aberdeen, whose originality of genius, ardent love of virtue, and early and extensive attainments in science and literature; raise him almost to the eminence of BARRETIER, of whom we have so pathetic an account from the pen of Johnson, I omitted with regret; but I thought not myself authorized to publish what his father had then only distributed among a few particular friends. For the omission of the life of Soame Jenyns I can make no apology: it was the consequence of forgetfulness.

FOR the *errors* of these two volumes, whether typographical or of a nature more important, I have perhaps no occasion to solicit greater indulgence than will be voluntarily extended to me by a generous public. The progress, however, of science, and of the revolutionary events in Europe, has been such, since great part of them was printed, that I must request the reader, in justice to myself, to proceed directly from the article GALVANISM to TORPEDO, and from REVOLUTION to the life of Marshal SUWOROW.

UNDER the title TRANSLATION, both in the Encyclopædia and in the Supplement, expressions are made use of, which may lead the reader to suppose that Mr Fraser Tytler was indebted for the general laws of the art, which he so ably illustrates, to Dr Campbell's Preliminary Dissertations to his Translation of the Gospels. It is but justice to declare my perfect

perfect conviction, as it was that of Dr Campbell himself, that Mr Tytler and he were equally intitled to the merit of having discovered those laws; and that however coincident in opinion, neither of them, when composing their separate works, had the smallest suspicion that the other had ever employed his thoughts on the subject. The only difference seems to have been in the mode of their discovery: Mr Tytler having deduced the laws of the art by regular analytical inference from his own description of a perfect translation; whereas Dr Campbell appears to have fortunately discovered them without that process of deduction.

The publisher begs leave to add to the foregoing, that the different Geographical articles so far as relate to America are taken from the Rev. Dr Morse's American Gazetteer. The article *United States* is extracted from the new Edition of Dr Morse's Universal Geography, and the article *New England* was written by the same author on purpose for this Supplement. The account of the Lucernal Microscope under the head of *Optics* was furnished by the Rev. Dr John Prince, the author of the improvements. The description of the *American Air Pump* in the article *Pneumatics*, was likewise inserted by permission of Dr Prince, the inventor. The corrections of the account of this Pump which was published in the Encyclopædia, are original. The observations on Vision by Dr Hosack of New York were published by his permission. The two articles of *Artificial Horizon*, and the *New Log* are published in an appendix by permission of Mr Gould the Patentee.

SUPPLEMENT

TO THE

ENCYCLOPÆDIA.

AARONSBURG, a poſt town in Northumberland county, Pennſylvania, lies near the head of Penn's creek, it is chiefly a German ſettlement, about 30 miles weſterly from Lewiſburg and 40 W. by N. from Sunbury, 160 miles W. N. W. from Philadelphia.—*Morse.*

ABACISCUS, in architecture, the ſame with ABACUS; for which, ſee *Encyclopædia.*

ABACOOCHEE, or *Cooſee*, a large river riſing in the S. W. Territory, paſſing into Georgia, through the Cherokee into the Creek country, where it unites with the Oakfuſkee, and forms the Alibama.—*Morse.*

ABATIS, or ABATTIS, is, in military language, the name of a kind of retrenchment made of felled trees. When the emergency is ſudden, the trees are merely laid lengthwiſe beſide each other, with their branches pointed towards the enemy, to prevent his approach, whilſt the trunks ſerve as a breaſtwork before thoſe by whom the abatis is raiſed. When the abatis is meant for the defence of a paſs or entrance, the boughs of the trees are generally ſtripped of their leaves and pointed; the trunks are planted in the ground; and the boughs are interwoven with each other. It is needleſs to add that the cloſer the trees are laid or planted together, the more ſecure is the defence which they afford; and if, when they are planted, a ſmall ditch be dug towards the enemy, and the earth thrown up properly againſt the lower part of the abatis, it will be very difficult to paſs it if well defended.—*Simes's Military Guide.*

ABBEVILLE *County*, in Ninety-ſix diſtrict, S. Carolina, bounded on the N. E. by the Saluda, and on the S. W. by the Savannah, is 35 miles in length and 21 in breadth; contains 9197 inhabitants, including 1665 ſlaves. The ſoil is rich and well watered. —*Morse.*

ABBREVIATION OF FRACTIONS, in arithmetic and algebra, is the reducing of them to lower terms; which is done by dividing the numerator and denominator by ſome number or quantity which will divide both without leaving a remainder of either.

ABERRATION, in optics (in Encycl.), refers the reader to the article OPTICS, n° 17, 136, 173. It ſhould have referred him to OPTICS, n° 17, and 251—256.

ABERRATION of the Viſual Ray, is a phenomenon, of which, though ſome account of it has been given in the Encyclopædia (ſee ABERRATION, in aſtronomy; and the article ASTRONOMY, n° 337.), one of the moſt candid of our correſpondents requires a fuller explanation. If ſuch an explanation be requiſite to him, it muſt be much more ſo to many others; and we know not where to find, or how to deviſe, one which would be more ſatisfactory, or more familiar, than the following by Dr. Hutton.

"This effect (ſays he) may be explained and familiarized by the motion of a line parallel to itſelf, much after the manner that the compoſition and reſolution of forces are explained. If light have a progreſſive motion, let the proportion of its velocity to that of the earth in her orbit be as the line BC to the line AC; then, by the compoſition of theſe two motions, the particle of light will ſeem to deſcribe the line BA or DC, inſtead of its real courſe BC; and will appear in the direction AB or CD, inſtead of its true direction CB. So that if AB repreſent a tube, carried with a parallel motion by an obſerver along the line AC, in the time that a particle of light would move over the ſpace BC, the different places of the tube being AB, *ab*, *cd*, CD; and when the eye, or end of the tube, is at A, let a particle of light enter the other end at B; then when the tube is at *ab*, the particle of light will be at *e*, exactly in the axis of the tube; and when the tube is at *cd*, the particle of light will arrive at *f*, ſtill in the axis of the tube; and, laſtly, when the tube arrives at CD, the particle of light will arrive at the eye or point C, and conſequently will appear to come in the direction DC of the tube, inſtead of the true direction BC: and ſo on, one particle ſucceeding another, and forming a continued ſtream or ray of light in the apparent direction DC. So that the apparent angle made by the ray of light with the line AE is the angle DCE, inſtead of the true angle BCE; and the difference BCD, or ABC, is the quantity of the aberration." Plate II. fig. 1.

ABERRATION of the Planets, is equal to their geocentric motion, or, in other words, to the ſpace which each appears to move as ſeen from the earth, during the time that light employs in paſſing from the planet to the eye of the obſerver. Thus the ſun's aberration in longitude is conſtantly 20″, that being the ſpace actually moved by the earth; but apparently by the ſun in 8 minutes and 7 ſeconds, the time in which light paſſes from the ſun to the earth. If then the diſtance of any ter, at all distances, tending towards each other by a fixed law, we might be led to consider mutual attraction as an *essential* property of that substance, and think no more of inquiring into its cause, than we think of inquiring into the cause of extension. But when we find that the same particles, which at one distance seem to attract each other, are at a different distance kept asunder by a power of repulsion, which no force, with which we are acquainted, is able to overcome, we cannot attribute the *principle* or *cause* of these changes to brute matter, but must refer it to some other agent exciting power according to a fixed law.

It is the fashion at present to despise all metaphysical inquiries as abstruse and useless; and on this account we doubt not but some of our readers will turn away from this disquisition with affected disgust, whilst the petulant and unthinking chemist, proud of possessing the secrets of his science, will deem it superfluous to inquire after any other natural agents than those of which he has been accustomed to talk. But with the utmost respect for the discoveries made by modern chemists, which we acknowledge to be both numerous and important, we beg leave to observe, that though these gentlemen have brought to light many events and operations of nature formerly unknown, and have shown that those operations are carried on by established laws, none of them can say with certainty that he has discovered a single agent. The most enlightened of them indeed pretend not to have discovered in one department of science more than Newton discovered in another; for they well know that agents and agency cannot be subjected to any kind of physical experiments. Our very notions of these things are derived wholly from our own consciousness and reflection; and when it is considered what dreadful consequences have in another country resulted from that pretended philosophy which excludes the agency of mind from the universe, it is surely time to inquire whether our consciousness and reflection do not lead us to refer real agency to mind alone. Let this be our apology both to the real and to the affected enemies of metaphysics for endeavouring to draw their attention to the present question. It is a question of the utmost importance, as well to science as to religion, and if the laws of human thought decide it, as we have endeavoured to show that they do, we may without hesitation affirm, that the impious philosophy of France can never gain ground but among men incapable of patient thinking.

ACTON, a township in Middlesex county, Massachusetts, containing 853 inhabitants; 24 miles N. W. of Boston.—*Morse.*

ACWORTH, a township in Cheshire county, New-Hampshire, incorporated in 1766, and contains 704 inhabitants; 8 miles E. by N. from Charlestown, and 73 N. W. by W. from Portsmouth.—*ib.*

ADAMAS, a name given, in astrology, to the moon.

ADAMS, a township in Berkshire county, Massachusetts, containing 2040 inhabitants, is about 140 miles N. W. of Boston. In the northern part of this town, is a great natural curiosity. A pretty mill stream, called Hudson's Brook, which rises in Vermont, and falls into the north branch of Hoosuck river, has, for 30 or 40 rods, formed a very deep channel, in some places 60 feet deep, through a quarry of white marble. Over this channel, where deepest, some of the rocks remain, and form a natural bridge. From the top of this bridge to the water, is 62 feet; its length is about 12 or 15, and its breadth about 10. Partly under this bridge, and about 10 or 12 feet below it, is another, which is wider, but not so long; for at the east end they form one body of rock, 12 or 14 feet thick, and under this the water flows. The rocks here are mostly white, and in other places clouded, like the coarse marble common at Lanesborough, and in other towns in Berkshire county.—*Morse.*

ADDISON *County*, in Vermont, is on the east side of Lake Champlain, and is divided nearly into equal parts by Otter creek; has Chittenden county on the N. and Rutland county on the S. and contains 6449 inhabitants, dispersed in 21 townships. It is about 30 miles by 27: a range of the green mountains passes through it. Chief town Middlebury, granted Nov. 1761.—*ib.*

ADSON's *Town*, lies near the N. E. line of New-Jersey, and S. E. of the Drowned Lands; 27 miles N. of Morristown, and 24 N. W. of Patterson.—*ib.*

ÆOLUS, in mechanics, a small machine invented by Mr. Tidd for refreshing or changing the air in rooms when it becomes too hot or otherwise unfit for respiration. The æolus is so contrived as to supply the place of a square of glass in the window, where it works, with very little noise, like the sails of a wind-mill or a smoke-jack.

AEROLOGY is a branch of science which was detailed in the Encyclopædia at sufficient length, and according to the principles which were then generally admitted by chemists. Subsequent experiments, however, have shown, that some of those principles are erroneous, and of course that some of the opinions advanced in the article AEROLOGY are inconsistent with facts. These opinions must be corrected; but instead of swelling this volume with a new article AEROLOGY, we apprehend that it will be more acceptable to our scientific readers to refer them for those corrections to the article CHEMISTRY in this Supplement.

AFFUERA, one of the islands of Juan Fernandes, on the South Sea coast, in the kingdom of Chili. Long. from the meridian of Callao, 30. 20. about 400 leagues to the N. of Cape Horn. This coast swarms with sea lions and wolves.—*Morse.*

AFGHANS, are a people in India who inhabit a province of CABUL or CABULISTAN (see Encycl.), and have always been connected with the kingdoms of Persia and Hindostan. They boast of being descended of Saul the first king of Israel; of whose advancement to the royal dignity they give an account which deviates not very widely from the truth. They say indeed, that their great ancestor was raised from the rank of a shepherd, not for any princely qualities which he possessed, but because his stature was exactly equal to the length of a rod which the angel Gabriel had given to the prophet Samuel as the measure of the stature of him whom God had destined to fill the throne of Israel.

SAUL, whose descent, according to some of them, was of Judah, and according to others of Benjamin, had, they say, two sons, BERKIA and IRMIA, who served David, and were beloved by him. The sons of Berkia and Irmia were AFGHAN and USBEC, who, during the

the reigns of David and Solomon, diſtinguiſhed themſelves, the one for his corporeal ſtrength, and the other for his learning. So great indeed was the ſtrength of *Afghan*, that we are told it ſtruck terror even into demons and genii.

This hero uſed frequently to make excurſions to the mountains; where his progeny, after his death, eſtabliſhed themſelves, lived in a ſtate of independence, built forts, and exterminated infidels. When the ſelect of creatures (the appellation which this people give to *Mahomet)* appeared upon earth, his fame reached the *Afghans*, who ſought him in multitudes under their leaders *Khalid* and *Abdul Reſpid*, ſons of *Walid;* and the prophet honouring them with this reception—"Come, O *Muluc*, or Kings!" they aſſumed the title of *Melic*, which they retain to this day.

The hiſtory, from which this abſtract is taken, gives a long and unintereſting detail of the exploits of the Afghans, and of their zeal in overthrowing the temples of idols. It boaſts of the following monarchs of their race who have ſat upon the throne of *Dehli:* Sultan Behlole, *Afghan* Lodi, Sultan Secander, Sultan Ibrahim, Shir Shah, Islam Shah, Adil Shah Sur. It alſo numbers the following kings of *Gaur* deſcended of the Afghan chiefs: Solaiman *Shah Gurzani*, Beyazid *Shah*, and Kutb *Shah;* beſides whom, their nation, we are told, has produced many conquerors of provinces. The Afghans are ſometimes called *Solaimani*, either becauſe they were formerly the ſubjects of Solomon king of Iſrael, or becauſe they inhabit the mountains of Solomon. They are likewiſe called Patans, a name derived from the *Hindi* verb *Paitna* "to ruſh" which was given to them by one of the Sultans whom they ſerved, in conſequence of the alacrity with which they had attacked and conquered his enemies. The province which they occupy at preſent was formerly called *Roh*; and hence is derived the name of the *Rohillas*. The city which was eſtabliſhed in it by the *Afghans* was called by them *Paiſhwer* or *Paiſher*, and is now the name of the whole diſtrict. The ſects of the Afghans are very numerous; of which the principal are, *Lodi, Lohouni, Sur, Serwani, Yuſufzihi, Bangiſh, Dilazaui, Khetti, Yaſin, Khail*, and *Beloje*. They are *Muſulmans*, partly of the *Sunni*, and partly of the *Shiek* perſuaſion.

Though they are great boaſters, as we have ſeen, of the antiquity of their origin, and the reputation of their race, other *Muſulmans* reject their claim, and conſider them as of modern, and even of baſe extraction.

This is probably a calumny; for it ſeems inconſiſtent with their attention to the purity of their deſcent—an attention which would hardly be paid by a people not convinced of their own antiquity. They are divided into four claſſes. The firſt is the *pure* claſs, conſiſting of thoſe whoſe fathers and mothers were *Afghans*. The ſecond claſs conſiſts of thoſe whoſe fathers were *Afghans* and mothers of another nation. The third claſs contains thoſe whoſe mothers were *Afghans* and fathers of another nation. The fourth claſs is compoſed of the children of women whoſe mothers were *Afghans* and fathers and huſbands of a different nation. Perſons who do not belong to one of theſe claſſes are not called *Afghans*.

This people have at all times diſtinguiſhed themſelves by their courage, both ſingly and unitedly, as principals and auxiliaries. They have conquered for their own princes and for foreigners, and have always been conſidered as the main ſtrength of the army in which they ſerved. As they have been applauded for virtues, they have alſo been reproached for vices, having ſometimes been guilty of treachery, and of acting the baſe part even of aſſaſſins.

Such is the account of the Afghans publiſhed in the ſecond volume of the Aſiatic Reſearches. It was tranſlated from a Perſian abridgment of a book written in the Puſhto language, and called *The Secrets of the Afghans*, and communicated by Henry Vanſittart, Eſq; to Sir William Jones, then Preſident of the Aſiatic Society. Their claim to a deſcent from Saul king of Iſrael, whom they call Melic Talut, is probably of not a very ancient date; for the introduction of the angel Gabriel with his rod, gives to the whole ſtory the air of one of thoſe many fictions which Mahomet borrowed from the later rabbins. Sir William Jones, however, though he ſurely gave no credit to this fable, ſeems to have had no doubt but the Afghans are deſcendants of Iſrael. "We learn (ſays he) from Esdras, that the ten tribes, after a wandering journey, came to a country called *Arſareth*, where we may ſuppoſe they ſettled: now the *Afghans* are ſaid by the beſt *Perſian* hiſtorians to be deſcended from the *Jews*. They have traditions among themſelves of ſuch a deſcent; and it is even aſſerted, that their families are diſtinguiſhed by the names of *Jewiſh* tribes, although, ſince their converſion to *Iſlam*, they ſtudiouſly conceal their origin from all whom they admit not to their *ſecrets*. The *Puſhto* language, of which I have ſeen a dictionary, has a maniſeſt reſemblance to the *Chaldaick;* and a conſiderable diſtrict under their dominion is called *Hazareh* or *Hazaret*, which might eaſily have been changed into the word uſed by Esdras. I ſtrongly recommend an inquiry into the literature and hiſtory of the *Afghans*."

It is to co-operate with this accompliſhed ſcholar that we have inſerted into our Work this ſhort account of that ſingular people; and it is with pleaſure that, upon the authority of Mr Vanſittart, we can add, that a very particular account of the *Afghans* has been written by the late Hafiz Rahmat *Khan*, a chief of the *Rohillahs*, from which ſuch of our readers as are oriental ſcholars may derive much curious information.

AGAMENTICUS, a mountain of conſiderable elevation in the diſtrict of Maine, diſtant about ſix miles from Bald Head, and eight from York harbor. Lat. 43. 16. N. and 70. 39. W. long. from Greenwich. It is a noted land-mark for ſeamen, and is a good directory for the entry of Paſcataqua harbor, as it lies very nearly in the ſame meridian with it, and with Pigeon Hill, on Cape Ann. The mountain is covered with wood and ſhrubs, and affords paſture up to its ſummit, where there is an enchanting proſpect. The cultivated parts of the country, eſpecially on the S. and S. W. appear as a beautiful garden, interſected by the majeſtic river Paſcataqua, its bays and branches. The immenſe ranges of mountains on the N. and N. W. afford a ſublime ſpectacle; and on the ſea ſide, the various indentings of the coaſt, from Cape Ann to Cape Elizabeth, are plainly in view in a clear day; and the Atlantic ſtretches to the E. as far as the power of viſion extends. At this ſpot the bearings of the following objects were taken, with a good ſurveying inſtrument, October 11, 1780.

Submit of the White Mountains, N. 15. W.
Cape Porpoise, N. 63. E.
Rochester Hill, N. 64. W.
Tuckaway South Peak, S. 80. W.
Frost's Hill, Kittery, S. 57. W.
Saddle of Bonabeag, N. 14. W.
Isle of Shoals Meeting-house, S. 6. E.
Varney's Hill, in Dover, distant 10¼ miles by mensuration, N. 89. W. Variation of the Needle, 6. W.—*Morse.*

ALABAMA, an Indian village, delightfully situated on the banks of the Mississippi, on several swelling green hills, gradually ascending from the verge of the river. These Indians are the remains of the ancient Alabama nation, who inhabited the east arm of the *Great Mobile river*, which still bears their name, now possessed by the Creeks, or Muscogulges, who conquered the former.—*ib.*

ALABAMA *River*, is formed by the junction of the *Coosa* or *Coosee*, or *High Town river*, and Tallapoosee river, at Little Tallasee, and runs in a S. W. direction, until it meets Tombigbee river from the N. W. at the great island which it there forms, 90 miles from the mouth of Mobile bay, in the gulf of Mexico. This beautiful river has a gentle current, pure waters, and excellent fish. It runs about 2 miles an hour, is 70 or 80 rods wide at its head, and from 15 to 18 feet deep, in the driest season. The banks are about 50 feet high, and seldom, if ever, overflowed. Travellers have gone down in large boats, in the month of May, in 9 days from Little Tallasee to Mobile bay, which is about 350 miles by water. Its banks abound with valuable productions in the vegetable and mineral kingdoms.—*ib.*

ALABASTER, or *Eleuthera*, one of the Bahama or Lucayo islands, on which is a small fort and garrison. It is on the Great Bahama Bank. The soil of this island, and Harbor Island, which lies at the north end of it, is better than Providence Island, and produces the greatest part of the pine-apples that are exported; the climate is very healthy. N. lat. 25. to 26. W. long. 75. to 76. 5.—*ib.*

ALACHUA SAVANNAH, is a level green plain, in the country of the Indians of that name, in E. Florida, situated about 75 miles west from St. Augustine. It is above 15 miles over, and 50 in circumference; and scarcely a tree or bush of any kind to be seen on it. It is encircled with high sloping hills, covered with waving forests, and fragrant orange groves, rising from an exuberantly fertile soil. The ancient *Alachua* town stood on the borders of this savannah; but the Indians removed to *Cuscowilla*, 2 miles distant, on account of the unhealthiness of the former scite, occasioned by the stench of the putrid fish and reptiles, in the summer and autumn, driven on shore by the alligators, and the noxious exhalations from the marshes of the savannah. Though the horned cattle and horses bred in these meadows are large, sleek, sprightly, and fat, yet they are subject to mortal diseases; such as the water rot, or scald, occasioned by the warm water of the savannah; while those which range in the high forests are clear of this disorder.—*ib.*

ALACRANES, LOS, a long range of shoals, banks, and rocks, on the south side of the gulph of Mexico, opposite the peninsula of Yucatan, east from Stone Bank, and west from Cape St. Antonio; within the 23d deg. of N. lat. and between the 89th and 91st degrees of W. long.—*Morse.*

ALASKA, a long peninsula on the N. W. coast of America, formed by Bristol bay and the ocean on the N. W. and N. and by the ocean and the waters of Cook's river on the S. and S. E. At its extremity are a number of islands, the chief of which, in their order westward, are, Oonemak, Oonalasha, and Ocumnak, which form part of the chain or cluster of islands called the Northern Archipelago. Capt. Cook, on his return in 1779, passed through the channel east of Oonemak island. See *N. W. Coast of America.*—*ib.*

ALATAMAHA, a navigable river of Georgia. It rises in the Cherokee mountains, near the head of a western branch of Savannah river, called Tugulo. In its descent through the mountains it receives several auxiliary streams; thence it winds, with considerable rapidity, through the hilly country 250 miles, from whence it throws itself into the open, flat country, by the name of *Oakmulgee*. Thence, after meandering for 150 miles, it is joined by the *Oconee*, which likewise has its source in the mountains. After this junction, it assumes the name of Alatamaha, when it becomes a large majestic river; and flowing with a gentle current through forests and plains 100 miles, discharges itself into the Atlantic by several mouths. The north channel glides by the heights of Darien, about 10 miles above the bar, and after several turnings, enters the ocean between Sapelo and Wolf islands. The south channel, which is esteemed the largest and deepest, after its separation from the north, descends gently, taking its course between M'Intosh and Broughton islands; and at last by the west coast of St. Simon's sound, between the south end of the island of that name, and the north end of Jekyl island. At its confluence with the Atlantic, it is 500 yards wide.—*ib.*

ALBAN's St. a township in Franklin county, Vermont, on Lake Champlain, opposite N. Hero island, 256 inhabitants.—*ib.*

ALBANY *County*, on Hudson's river, in the state of New-York, lies between Ulster and Saratoga; its extent 46 miles by 28. By the state census, Jan. 20, 1796, the number of electors in this county were 6087, and the number of towns 11.—*ib.*

ALBANY, the chief town of the above county, is situated on the west bank of Hudson's river, 160 miles north of the city of New-York, to which it is next in rank, and 340 S. of Quebec. N. lat. 42. 39. W. long. 73. 30. This city and suburbs, by enumeration in 1797, contained 1263 buildings, of which 863 were dwelling-houses, and 6021 inhabitants. Many of them are in the Gothic style, with the gable end to the street, which custom the first settlers brought from Holland; the new houses are built in the modern style. Its inhabitants are collected from various parts of the world, and speak a great variety of languages, but the English predominates; and the use of every other is gradually lessening. Albany is unrivalled for situation, being nearly at the head of sloop navigation, on one of the noblest rivers in the world. It enjoys a salubrious air, and is the natural emporium of the increasing trade of a large extent of country W. and N.—a country of an excellent soil, abounding in every article

article for the W. India market; plentifully watered with navigable lakes, creeks and rivers, settling with almost unexampled rapidity, and capable of affording subsistence to millions of inhabitants: and when the contemplated locks and canals are completed, and convenient roads opened into every part of the country, all which will, it is expected, be accomplished in the course of a few years, Albany will probably increase and flourish beyond almost any other city or town in the United States. The public buildings are, a Low Dutch church, of ancient and very curious construction, one for Episcopalians, two for Presbyterians, one for Germans, or High Dutch, and one for Methodists; an hospital, city hall, and a handsome brick jail. The corporation consists of a mayor, recorder, six aldermen, and as many assistants. In the year 1609, Henry Hudson, whose name the river bears, ascended it in his boat to *Aurania*, the spot on which Albany now stands.

The improvements in this city, within 5 or 6 years past, have been very great in almost all respects. Wharves have been built on the river, the streets have been paved, a bank instituted, a new and handsome style of building introduced, and now excellent water (an article in which this city has hitherto been extremely deficient, having been obliged to use the dirty water of the river) is about to be conducted into the various parts of the city, from a fine spring 5 miles west of the city. For these improvements the inhabitants are indebted to the patriotic exertions of a very few gentlemen.

One mile north of this city, in its suburbs, near the manor house of lieutenant governor Van Renssalaer, are very ingeniously constructed, extensive and useful works, for the manufacture of Scotch and rappee snuff, roll and cut tobacco of different kinds, chocolate, mustard, starch, hair powder, split pease, and hulled barley. These valuable works are the property of Mr. James Caldwell, who unfortunately lost a complete set of similar works, by fire, in July, 1794, with the stock, valued at 37,500 dollars. It is a circumstance worthy of remark, and is evincive of the industry and enterprize of the proprietor, that the whole of the present buildings and machinery were begun and completed in the short space of eleven months. These works are decidedly superior to any of the kind in America. All the articles above enumerated, even to the spinning of tobacco, are manufactured by the aid of water machinery. For the invention of this machinery the proprietor has obtained a patent. These works give employment and subsistence to 40 poor boys, and a number of workmen. Men who make such efforts to advance American manufactures, deserve well of their country.—*Morse*.

Albany, a British fortress in New South Wales, in N. America, situated on the river of the same name. N. lat. 53. 10. W. long. 87. 20.—*ib*.

Albany *River*, falls into James's bay, in N. America, in N. lat. 51. 30. W. long. 84. 30. This river runs in a N. E. direction, and has communication with a vast chain of small lakes, in a line S. W. to the S. end of Winnipeg lake, a body of water next in size to Lake Superior.—*ib*.

ALBATEGNI, an Arabic prince of Batan in Mesopotamia, was a celebrated astronomer, about the year of Christ 880, as appears by his observations. He is also called *Muhammed ben Geber Albatani*, *Mahomet the son of Geber*, and *Muhamedes Aractensis*. He made astronomical observations at Antioch, and at Racah or Aracta, a town of Chaldea, which some authors call a town of Syria or of Mesopotamia. He is highly spoken of by Dr Halley, as *vir admirandi acuminis, ac in administrandis observationibus exercitatissimus*.

Finding that the tables of Ptolemy were imperfect, he computed new ones, which were long used as the best among the Arabs: these were adapted to the meridian of Aracta or Racah. Albategni composed in Arabic a work under the title of *The Science of the Stars*, comprising all parts of astronomy, according to his own observations and those of Ptolemy. This work, translated into Latin by Plato of Tibur, was published at Nuremberg in 1537, with some additions and demonstrations of Regiomontanus; and the same was reprinted at Bologna in 1645, with this author's notes. Dr Halley detected many faults in these editions.—*Phil. Trans.* for 1693, N° 204.

In this work Albategni gives the motion of the sun's apogee since Ptolemy's time, as well as the motion of the stars, which he makes one degree in 70 years. He made the longitude of the first star of Aries to be 18° 2′; and the obliquity of the ecliptic 23° 35′. And upon Albategni's observations were founded the Alphonsine tables of the moon's motions; as is observed by Nic. Muler, in the *Tab. Frisicæ*, p. 248.

ALBEMARLE *County*, in Virginia, lies between the Blue ridge and the tide waters, and contains 12,585 inhabitants, including 5579 slaves. Its extent about 35 miles square.—*Morse*.

Albemarle Sound, on the coast of North-Carolina, is a kind of inland sea, 60 miles in length, and from 8 to 12 in breadth. It lies north of Pamplico Sound, and communicates with it; as it likewise does with Currituck Inlet. It receives Roanoke and Meherrin rivers; and the passage into it from the sea is called Roanoke Inlet.—*ib*.

ALDERAIMIN, a star of the third magnitude, in the right shoulder of the constellation Cepheus.

ALEXANDRIA, a township in Grafton county, New-Hampshire, containing 298 inhabitants; incorporated in 1782.—*Morse*.

Alexandria, a township in Hunterdon county, New-Jersey, containing 1503 inhabitants, inclusive of 40 slaves.—*ib*.

Alexandria, a small town in Huntingdon county, Pennsylvania, on the Frankstown branch of Juniata river; 192 miles N. W. of Philadelphia.—*ib*.

Alexandria, formerly called *Belhaven*, a city in Virginia, situated on the southern bank of the Patowmac river, in Fairfax county, about 5 miles S. W. from the Federal City, 60 S. W. from Baltimore, 60 N. from Fredericksburgh, 168 N. of Williamsburgh, and 290 from the sea; 38. 45. N. lat. and 77. 10. W. long. Its situation is elevated and pleasant. The soil is clayey. The original settlers, anticipating its future growth and importance, laid out the streets on the plan of Philadelphia. It contains about 400 houses, many of which are handsomely built, and 2748 inhabitants. This city, upon opening the navigation of Patowmac river, and in consequence of its vicinity to the future seat of the federal government, bids fair to be one of the

the most thriving commercial places on the continent. —*Morse*.

ALFORD, a township in Berkshire county, Massachusetts, containing 577 inhabitants; 145 miles westward from Boston.—*ib*.

ALFRAGAN, Alferganı, or *Fargani*, a celebrated Arabic astronomer, who flourished about the year 800. He was so called from the place of his nativity, Fergan, in Sogdiana, now called Maracanda, or Samarcand, anciently a part of Bactria. He is also called *Ahmed* (or *Muhammed) ben Cothair*, or *Katir*. He wrote the Elements of Astronomy in 30 chapters or sections. In this work the author chiefly follows Ptolemy, using the same hypothesis, and the same terms, and frequently citing him. Of Alfragan's work there are three Latin translations, of which the last and best was made by Golius, professor of mathematics and oriental languages in the university of Leyden. This translation, which was published in 1669, after the death of Golius, is accompanied with the Arabic text, and with many learned notes on the first nine chapters, which would undoubtedly have been carried to the end, had the translator lived to complete his plan.

ALGORAB, a fixed star of the third magnitude, in the right wing of the constellation Corvus.

ALHAZEN, an Arabian astronomer, who flourished in Spain about the beginning of the 12th century. See Astronomy, n° 6. Encycl.

ALKANSAS, or *Arkansas*, an Indian nation in Louisiana, on the west side of Mississippi river, near the river of the same name, in N. lat. 34. See *Arkansas River*.—*Morse*.

ALLBURG, a township in Franklin county, Vermont, containing 446 inhabitants; situated on *Missisque Bay*.—*ib*.

ALLEGHANY *Mountains*. See Appalachian, *Encyclopædia*.

Alleghany *River*, in Pennsylvania, rises on the western side of the Alleghany Mountain, and after running about 200 miles in a S. W. direction, meets the Monongahela at Pittsburg, and both united, form the Ohio. The lands on each side of this river, for 150 miles above Pittsburg, consist of white oak and chesnut ridges, and, in many places, of poor pitch pines, interspersed with tracts of good land, and low meadows. This river, and the Ohio likewise, from its head waters until it enters the Mississippi, are known and called by the name of Alleghany River, by the Seneca, and other tribes of the Six Nations, who once inhabited it.—*Morse*.

Alleghany *County*, in Pennsylvania, extends from the junction of the river of that name with the Ohio, where its chief town, Pittsburg, is situated, to the New-York line. It contains 10,309 inhabitants, including 159 slaves.—*ib*.

Alleghany, is the most western county in Maryland, and has Pennsylvania on the north. The windings of the Potowmac River separate it from Virginia on the south, and Sideling hill Creek divides it from Washington county on the east. It contains 4809 inhabitants, including 258 slaves. Cumberland is its chief town.—*ib*.

ALLEMAND, a river which falls into the Mississippi from the S. E. about 43 miles S. of the Natches. —*ib*.

ALLENSTOWN, a town in New-Jersey, in Monmouth county, 15 miles N. E. from Burlington, and 13 S. by E. from Princeton.—*Morse*.

Allenstown, a township in Rockingham county, New-Hampshire, containing 254 inhabitants; situated on the E. side of Merrimack river, 25 miles N. W. of Exeter, and 40 from Portsmouth.—*ib*.

ALLEN-TOWN, in Pennsylvania, Northampton county, on the point of land formed by Jordan's creek, and the Little Lehiegh. It contains about 90 houses, and an academy.—*ib*.

ALLOWAY *Creek*, in Salem county, New-Jersey, empties into the Delaware. It is navigable 16 miles, interrupted, however, by several draw-bridges.—*ib*.

ALL-SAINTS, a parish in Georgetown district, South-Carolina, containing 2225 inhabitants, of whom 429 are whites, and 1795 slaves. It sends a member to each house of the state legislature.—*ib*.

All-Saints *Bay*, a captainship in the middle division of Brazil, so called from a large bay of that name, bounded N. by the Ria Real; on the S. by that of Las Ilheos; on the E. by the ocean; and on the W. by three unconquered nations of Indians. It is reckoned one of the richest and most fertile captainships in all Brazil, producing great quantities of cotton and sugar. The bay itself is about 2½ leagues over, interspersed with a number of small, but pleasant islands, and is of prodigious advantage to the whole country. It has several cities and towns, particularly St. Salvador, which is its capital. All-Saints Bay lies in lat. 12. 3. S. long. 40. 10. W. See *Salvador*.—*ib*.

ALMAMON, was a philosopher and astronomer, who, in the beginning of the 9th century, ascended the throne of the caliphs of Bagdat. He was the son of Harun Al-Rashid, and grandson of Almansor. His name is otherwise written, *Mamon*, *Almaon*, *Almamun*, *Alamoun*, or *Al-Maimon*. Having been educated with great care, and with a love for the liberal sciences, he applied himself to cultivate and encourage them in his own country. For this purpose he requested the Greek emperors to supply him with such books on philosophy as they had among them; and he collected skilful interpreters to translate them into the Arabic language. He also encouraged his subjects to study them; frequenting the meetings of the learned, and assisting at their exercises and deliberations. He caused Ptolemy's Almagest to be translated in 827, by Isaac Ben-honain, and Thabet Ben-korah according to Herbelot, but, according to others, by Sergius, and Alhazen the son of Joseph. In his reign, and doubtless by his encouragement, an astronomer of Bagdat, named Habash, composed three sets of astronomical tables.

Almamon himself made many astronomical observations, and determined the obliquity of the ecliptic to be then 23° 35′ (or 23° 33′ in some manuscripts), but Vossius says 23° 51′ or 23° 34′. He also caused skilful observers to procure proper instruments to be made, and to exercise themselves in astronomical observations; which they did accordingly at Shemasi in the province of Bagdat, and upon Mount Cassius near Damus.

Under the auspices of Almamon also a degree of the meridian was measured on the plains of Sinjar or Sindgiar (or, according to some, Fingar), upon the borders of the Red Sea; by which the degree was found to contain 56⅔ miles, of 4000 coudees each, the coudee being

being a foot and a half: but it is not known what foot is here meant, whether the Roman, the Alexandrian, or ſome other. Riccioli makes this meaſure of the degree amount to 81 ancient Roman miles, which value anſwers to 62,046 French toiſes; a quantity more than the true value of the degree by almoſt one third. Finally, Almamon revived the ſciences in the Eaſt to ſuch a degree, that many learned men were found, not only in his own time, but after him, in a country where the ſtudy of the ſciences had been long forgotten. This learned king died near Tarſus in Cilicia, by having eaten too freely of ſome dates, on his return from a military expedition, in the year 833.

ALMSBURY, commonly called *Ameſbury*, is a flouriſhing town in Eſſex county, Maſſachuſetts, on the north weſtern bank of Merrimack river, about five miles N. W. of Newburyport, containing 1801 inhabitants. Powaws river divides the townſhip from Saliſbury, over which a handſome bridge has lately been erected. A number of mills lie on this river round the lower falls. See *Powaws river*.—*Morse*.

ALOE DICHOTOMA, in botany, called by the Dutch *Kooker-boom* or *Quiver-tree*, is a native of the ſouthern parts of Africa, and ſeems to be a ſpecies of the AGAVE or *American aloe* (ſee AGAVE, Encycl.) It is thus deſcribed by LE VAILLANT in his *New Travels into the Interior Parts of Africa*: "The *aloe dichotoma* riſes to the height of 25 or 30 feet; its trunk is ſmooth, and the bark white. When young, and the trunk not more than four or five feet long, it terminates with a ſingle tuft of leaves, which, like thoſe of the ananas, ſpread and form a crown, from the midſt of which all its flowers iſſue. As it grows older, it puſhes out lateral branches, perfectly regular and ſymmetrical, each of which has at its extremity a crown ſimilar to that of the young plant. The kooker-boom thrives much better on mountains than in the plain. Inſtead of long roots penetrating deep into the earth, like thoſe of other trees, it has but a very ſlight one by which it is fixed to the ſoil. Accordingly, three inches of mould are ſufficient to enable it to grow upon the very rocks, and attain its utmoſt beauty; but its root is ſo feeble a ſupport, that I could throw down the largeſt with a ſingle kick of my foot. The hordes on the weſt make their quivers of the trunk of this tree when young, whence is derived the name given it by the planters."

It becomes not us, ſitting in our chamber, to controvert a fact in natural hiſtory, of the reality of which we never had an opportunity of judging; nor would it be proper, on account of our own ſcepticiſm, to ſuppreſs the narrative of a traveller, who corrects the narratives of former travellers in terms which nothing ſhould have dictated but the conſciouſneſs of his own invariable veracity. Yet we hope to be pardoned for expreſſing our ſurpriſe that, in any part of the world, trees ſhould be found in great numbers 25 or 30 feet high, and ſhooting out many branches, which have yet ſo looſe a hold of the ground, that the largeſt of them may be thrown down by the ſingle kick of a man's foot. The reader's ſurpriſe will probably equal ours, when he is informed that the author ſaw one of theſe trees of which the trunk was ten feet four inches in circumference, whilſt its branches overſhadowed a ſpace of more than 100 feet in diameter! This tree he aſſures that he could have *kicked* over. The country, according to his account, is not exempted from ſtorms. He is himſelf a French philoſopher. What a pity then is it that he did not explain to thoſe, who have not had the benefit of being enlightened in that ſchool, upon what principle of mechanics or ſtatics the tree could reſiſt the violence of the elements till it arrived at ſo enormous a ſize?

ALPHONSUS X. king of Leon and Caſtile (ſee *Encycl.*) This prince underſtood aſtronomy, philoſophy, and hiſtory, as if he had been only a man of letters; and compoſed books upon the motions of the heavens, and on the hiſtory of Spain, which are highly commended. "What can be more ſurpriſing (ſays Mariana), than that a prince, educated in a camp, and handling arms from his childhood, ſhould have ſuch a knowledge of the ſtars, of philoſophy, and the tranſactions of the world, as men of leiſure can ſcarcely acquire in their retirements? There are extant ſome books of Alphonſus on the motions of the ſtars, and the hiſtory of Spain, written with great ſkill and incredible care." In his aſtronomical purſuits he diſcovered that the tables of Ptolemy were full of errors; and thence he conceived the firſt of any the reſolution of correcting them. For this purpoſe, about the year 1240, and during the life of his father, he aſſembled at Toledo the moſt ſkilful aſtronomers of his time, Chriſtians, Moors, and Jews, when a plan was formed for conſtructing new tables. This taſk was accompliſhed about 1252, the firſt year of his reign; the tables being drawn up chiefly by the ſkill and pains of Rabbi Iſaac Hazan, a learned Jew, and the work called the *Alphonſine Tables*, in honour of the prince, who was at vaſt expenſes concerning them. He fixed the epoch of the tables to the 30th of May 1252, being the day of his acceſſion to the throne. They were printed for the firſt time in 1483, at Venice, by Radtoldt, who excelled in printing at that time. This edition is extremely rare: there are others of 1492, 1521, 1545, &c.

In the Encyclopædia it is ſaid, that the charge of impiety brought againſt this prince was *unjuſt*. This was ſaid too confidently, becauſe we know not of any direct proof of his innocence. All that has been ſaid for him by Dr. Hutton, one of his ableſt apologiſts, amounts to nothing more than a high degree of probability that the charge was carried by much too far. The charge itſelf was, that Alphonſus affirmed, "that if he had been of God's privy council when he made the world, he would have adviſed him better." Mariana, however, ſays only in general, that Alphonſus was ſo bold as to blame the works of Providence, and the conſtruction of our bodies; and he ſays that this ſtory concerning him reſted only upon a vulgar tradition. The Jeſuit's words are curious: "Emanuel, the uncle of Sanchez (the ſon of Alphonſus), in his own name, and in the name of other nobles, deprived Alphonſus of his kingdom by a public ſentence; which that prince merited, for daring ſeverely and boldly to cenſure the works of Divine Providence, and the conſtruction of the human body, as tradition ſays he did. Heaven moſt juſtly puniſhed the folly of his tongue." Though the ſilence of ſuch an hiſtorian as Mariana, in regard to Ptolemy's ſyſtem, ought to be of ſome weight, yet we cannot think it improbable, that if Alphonſus did paſs ſo bold a cenſure on any part of the univerſe, it was on the celeſtial ſphere, and meant to glance upon the contrivers and ſupporters of that ſyſtem. For, beſides

sides that he studied nothing more, it is certain that at that time astronomers explained the motions of the heavens by intricate and confused hypotheses, which did no honour to God, nor any wise answered the idea of an able workman. So that, from considering the multitude of spheres composing the system of Ptolemy, and those numerous eccentric cycles and epicycles with which it is embarrassed, if we suppose Alphonsus to have said, "that if God had asked his advice when he made the world, he would have given him better counsel," the boldness and impiety of the censure will be greatly diminished.

Such is the apology made by Dr Hutton for this royal astronomer of Spain; and we hope, for the honour of science, that it is well founded. Still it leaves Alphonsus guilty of great irreverence of language, which is to us wholly unaccountable, if it be really true that he read the Bible fourteen times. We have seen impiety indeed break out lately from very eminent astronomers of a neighbouring nation; but these men read not the Bible, nor any thing else, but the dreams of the eternal sleepers.

ALSTEAD, a township in Cheshire county, New-Hampshire, containing 1111 inhabitants; 8 miles S. from Charlestown.—*Morse.*

ALTERNATE ANGLES. See GEOMETRY (Encycl.), Part I. 35.

ALTERNATE Ratio, or *Proportion*, is the ratio of the one antecedent to the other, or of one consequent to the other, in any proportion, in which the quantities are of the same kind. So if $A : B :: C : D$, then alternately, or by alternation $A : C :: B : D$.

ALTITUDE, PARALLAX OF, is an arch of a vertical circle, by which the true altitude, observed at the centre of the earth, exceeds that which is observed on the surface. See PARALLAX (Encycl.) and ASTRONOMY *(Suppl.)*

ALTITUDE of the Nonagesimal, is the altitude of the 90th degree of the ecliptic, counted upon it from where it cuts the horizon, or of the middle or highest point of it which is above the horizon, at any time; and is equal to the angle made by the ecliptic and horizon where they intersect at that time.

ALTITUDE of the Cone of the Earth's or Moon's Shadow, the height of the shadow of the body made by the sun, and measured from the centre of the body. To find it say, As the tangent of the angle of the sun's apparent semidiameter is to radius; so is 1 to a fourth proportional, which will be the height of the shadow in semidiameters of the body.

ALUM is a salt so useful in commerce and the arts, that the knowledge of its component parts, and of the best method of preparing it, must be of importance. In the article CHEMISTRY (Encycl.), the opinions which were then held respecting its composition, and the practice which was generally followed in its preparation, have been detailed at full length; but some of these opinions have since been controverted, and if they be erroneous, it must be expedient to vary in some degree the mode of preparation. In particular, the opinion that it is merely an excess of acid which prevents the formation of alum by evaporation of the ley, has been shown to be false by Citizen *Vauquelin*, who contends, of course, that the addition of putrid urine to the ley is a very bad practice.

This eminent chemist had long suspected, that the crystallization of alum is not prevented by an excess of acid, and that pot-ash is not of use simply to saturate this acid, but to perform an office of more importance. To bring his suspicions to the test of experiment, he dissolved very pure ALUMINE in sulphuric acid of equal purity, and evaporated the solution to dryness, for the purpose of expelling the superabundant acid. He then redissolved the dry and pulverulent residue in water, and reduced the solution to different degrees of specific gravity, with a view to seize the point most favourable to crystallization; but with every possible precaution he could obtain nothing but a magma (see MAGMA), formed of saline plates, without consistence or solidity. This solution, however, though it constantly refused to afford crystallized alum alone, afforded it immediately by the addition of a few drops of the solution of pot-ash; and as he had employed these two substances in the requisite proportion, the rest of the solution, to the very end, afforded pure alum, without any mixture of sulphate of pot-ash.

Into another portion of the same solution of pure alumine he dropped the same quantity of carbonate of soda, as he had added of that of pot-ash to the former; but no crystallization was formed, even by the help of evaporation, nor did lime and barytes produce any better effect. But if the common opinion that pot-ash, in the formation of alum, is of use only to abstract the excess of acid, be true, soda, lime, barytes, and all the substances which by a more powerful force would take this acid from alum, ought to give the same result. Another argument presented itself, which seemed decisive: If the alkalis, pot-ash, and ammoniac, do nothing more than unite to the superabundant acid of the alum, the sulphates of pot-ash and of ammoniac ought not to occasion any change in pure alum in its acidulated state; whereas if these alkalis enter as a constituent part into the alum, and are necessary to its existence, they ought to produce the same effects as pure pot-ash or ammoniac. He therefore added to a third portion of the solution of sulphate of alumine before-mentioned some drops of the solution of sulphate of pot-ash; immediately upon which octahedral crystals of alum were formed. The sulphate of ammoniac presented the same effect.

This result gave still greater confirmation to his first notions, though it did not yet afford a demonstration perfectly without objection; for it might have happened that the two salts he made use of might determine the crystallization of the alum, simply by absorbing the superfluous acid, of which they are very greedy; but to determine this possible fact, he mixed in the uncrystallizable solution of alumine some sulphate of pot-ash with excess of acid, and obtained a crystallization no less abundant than with the neutral sulphate of pot-ash.

This last experiment leaves therefore no doubt with regard to the influence and mode of action of pot-ash and ammoniac in the fabrication of alum; and this action is still more strongly confirmed by the examination of the alums which have been formed by the processes above related; for in this manner it is proved that they contain considerable quantities of the sulphates of pot-ash and ammoniac.

These experiments led M. Vauquelin to an examination of the different alums of commerce, of which he found not one that did not afford sulphate of pot-ash, or of ammoniac, or of both. His methods of analyſis are very accurate; but to detail them at length would ſwell this article to little purpoſe. To ſuch of our readers as are not chemiſts they would hardly be intelligible; and the experienced chemiſt will deviſe methods of analyſis for himſelf. It may be proper, however, to obſerve, that M. Vauquelin proved, to his own ſatiſfaction, that the ſulphate of pot-aſh, or of ammoniac, is neceſſary to render alum capable of being precipitated by its earth, or to cauſe it to paſs, as it were, to the earthy ſtate (A). He proved likewiſe, that ſuch aluminous waters as do not contain pot-aſh, may remain, as long as may be deſired, on their materials, without being ſaturated with too great a quantity of earth, or ſuffering alum to precipitate.

From the whole of his experiments our author drew the following concluſions, which he conſiders as of importance to the arts, to chemiſtry, and to natural hiſtory.

1. It is not, at leaſt in the greateſt number of circumſtances, the exceſs of acid which impedes the cryſtallization of alum, but it is the want of pot-aſh or ammoniac: For it is difficult to imagine that the ſulphuric acid could remain diſengaged after ſo long remaining upon alumine in a ſtate of extreme diviſion, and always ſuperabundant. It is true that the aluminous waters redden the vegetable tinctures; but this property is not owing to a diſengaged acid. This portion of acid is a conſtituent part of theſe waters; and it appears to have more affinity with the neutral ſulphate of alumine than with a new quantity of this earth at the temperature of the atmoſphere.

2. The ſulphate of pot-aſh may be uſed, as well as pure pot-aſh, to cauſe the cryſtallization of alum. It even has the advantage over the latter ſalt, becauſe if the aluminous waters do not really contain a diſengaged acid, the pot-aſh, in its combination, will precipitate a portion of alumine, and diminiſh the product of the boiling; whereas the ſulphate of pot-aſh does not produce the ſame effect; but if the lixiviums contain diſengaged acid, which muſt very ſeldom be the caſe, it is not converted into alum by the ſulphate of pot-aſh, and is loſt with regard to the product. Our author therefore is of opinion, that when the waters really contain an exceſs of acid, or a very oxided ſulphate of iron, the uſe of pot-aſh is preferable to that of the ſulphate of pot-aſh. But when economy is an object, that in many places it would be profitable to uſe the ſulphate of pot-aſh; becauſe it is a ſalt indirectly produced in many manufactories, where of courſe it may be obtained for nothing. In particular, the reſidues of the diſtillation of aquafortis by the ſulphuric acid would be excellent for this operation, and much preferable to putrid urine, becauſe this fluid always contains phoſphoric ſalts, which decompoſe a portion of the ſulphate of alumine, and conſiderably diminiſh the product.

3. Alumine cannot be uſed in the treatment of mother waters, as Bergman propoſes. This earth is incapable of favouring the cryſtallization of alum, beſides which, it decompoſes a portion of alum by the aſſiſtance of ebullition; in which circumſtance it ſeizes the acid neceſſary to its ſolution, and precipitates it in the form of that powder which is called alum ſaturated with its earth.

4. Many alum ores muſt naturally contain pot-aſh, becauſe perfect alum is often obtained from the firſt cryſtallization of new alum waters without the addition of this alkali. It is true that an objection may be made with regard to the wood uſed in calcining theſe ores, which may be ſuppoſed to have furniſhed the alkali; but it is not probable that the ſmall quantity of wood employed, in compariſon to the quantity of ore and the alum it affords, could ſupply enough of pot-aſh for the cryſtallization.

5. All the earths and ſtones which have given, or ſhall hereafter afford, by analyſis with the ſulphuric acid, perfect alum without addition of pot-aſh, muſt contain this alkali naturally. For it is well proved, that alum cannot exiſt without pot-aſh or ammoniac; and as there is little probability that this laſt ſhould be found combined in earths or ſtones, unleſs perhaps in very rare caſes, we may almoſt conſtantly be aſſured, when alum is obtained from any of theſe ſubſtances, that its formation was effected by pot-aſh. The quantity of alum will immediately ſhow in what proportion this alkali exiſted in the ſubſtances analyſed.

6. The alum of commerce ought not to be conſidered as a ſimple ſalt, but as a combination in the ſtate of a tripple and ſometimes quadruple ſalt of ſulphate of alumine, ſulphate of pot-aſh, or of ammoniac. Among theſe laſt we may diſtinguiſh two ſpecies; the one without exceſs of acid, inſoluble in water and inſipid, being what is improperly called alum ſaturated with its own earth; and the other, which contains an exceſs of acid ſoluble in water, very ſapid and aſtringent, is the common alum.

There is likewiſe a pure ſulphate of alumine, very aſtringent, very difficult of cryſtallization, in the form of brilliant pearl-coloured plates without conſiſtence, and which cannot be rendered ſoluble by the addition of a new quantity of its baſe. This laſt ſalt may with the greateſt propriety be called the ſulphate of alumine.

7. It follows from the comparative analyſis, and the knowledge acquired reſpecting the different ſtates of the combination of alumine with the ſulphuric acid united at the ſame time with other baſes, that we muſt diſtinguiſh ſeven ſtates in this combination, and that it is neceſſary to expreſs them according to the rules of the methodical nomenclature. Here follow the ſeries, the nature, and the names of theſe ſeven ſulphates of alumine.

1. Sulphate of alumine, or the artificial combination of ſulphuric acid and alumine. This ſalt is aſtringent; it cryſtallizes in laminæ or flexible leaves, ſoluble in water. It has never been deſcribed nor named by chemiſts. 2. Acid ſulphate of alumine is the foregoing ſalt, with exceſs of acid, from which it differs by reddening blue vegetable colours. It is eaſily made by diſſolving that ſalt in the ſulphuric acid, but it is not eaſy to convert this into the neutral ſulphate of alumine but by boiling it a long time with its earth. This ſalt, like the firſt, has not been deſcribed. 3. Saturated

(A) It may be proper to notice, that Scheele ſeems to have known this long before, and that he mentions it expreſsly in his paper on *Pyrophorus*.

fulphate of alumine and of pot-afh is the alum of the chemifts faturated with its earth. It is pulverulent, infipid, infoluble, not cryftallizable, and is eafily converted into true alum by the addition of fulphuric acid. 4. The acid fulphate of alumine and of pot-afh greatly refembles common alum, and is eafily prepared chemically; but M. Vauquelin found no alum but that of La Tolfa which is exactly of the fame nature with it. 5. The acid fulphate of alumine and of ammoniac has all the properties of alum, and may be ufed for the fame purpofes; but though it is eafily made in the laboratories, our author never found it pure in commerce. 6. The acid fulphate of alumine, pot-afh, and ammoniac. It is remarkable enough, fays M. Vauquelin, that this fhould be the nature of the alum moft frequently made in the arts, and that to exprefs its combination fo many words fhould be neceffary. This, however, may be avoided, by referving the name of alum to this fubftance, which will be fufficient to diftinguifh it perfectly. 7. The acidulous fulphate of alumine and of pot-afh, our author fays, he is lefs acquainted with than with the preceding feries. The name by which he characterizes it was fuggefted to him, and he thinks it proper, becaufe by adding to the folution a fmall quantity of pot-afh more than is neceffary to obtain octahedral cryftals, it manifeftly paffes to the cubic form.

From thefe deductions, the phyfician, the chemift, and the manufacturer, with whom the ufes of alum are greatly multiplied, will hereafter poffefs a knowledge of the fubftance they employ, and may appreciate its effects on the animal economy, and other bodies to which it is fo frequently applied. See *Annales de Chimie*, xxii. 258, and *Nicholfon's Journal*, Vol. I. p. 318, &c.

ALUMINE, one of the fimple earths. See CHEMISTRY in this *Supplement*.

ALVARADO, a river in New Spain, which rifes in the mountains of the Zapotecas, and, after making a circuit through the province of Mazaltan, and receiving feveral fmaller rivers and ftreams, empties into the Gulf of Mexico, at 30 miles diftance from Vera-Cruz.—*Morse*.

AMBROSE, ST. an ifland in the S. Pacific ocean, on the coaft of Chili, 4 or 5 leagues due W. from St. Felix ifland. At firft view, it appears like two fmall iflands, but after a nearer approach, it is found they are joined by a reef. It lies in 26. 13. S. lat. and 80. 55. W. long. from Greenwich. There is a large rock 4 miles to the northward of the ifland, called, from its appearance, *Sail rock*. Capt. Roberts, who was here in 1792, found St. Felix ifland inacceffible. On St. Ambrofe ifland, his crew killed and cured 13,000 feal fkins of the beft quality, in feven weeks. The ifland has little elfe to recommend it. Fifh and crawfifh abound. The beft feafon for fealing is from the 1ft of April to the 1ft of Auguft. The ifland has the appearance of having had volcanic eruptions.—*ib.*

AMELIA, a county in Virginia, bounded N. by Appamatox river which feparates it from Powhatan and Chefterfield counties, N. W. by Prince Edward, E. by Dinwiddie, and S. by Nottaway. *Scott.* Amelia, including Nottaway, a new county, contains 18,097 inhabitants, of whom 11,037 are flaves.

AMELIA *Ifle*, on the coaft of E. Florida, lies about 7 leagues N. of St. Auguftine, and very near Talbot ifland on the S. at the mouth of St. John's river. It is 13 miles long and 2 broad, is very fertile, and has an excellent harbour. Its N. end lies oppofite Cumberland ifland, between which and Amelia Ifle is the entry into St. Mary's river, in N. lat. 30. 52. W. long. 67. 23.—*Morse*.

AMICABLE NUMBERS have been defined, and the firft pair of them given in the Encyclopædia. The fecond pair of amicable numbers are 17296 and 18416; and the third pair are 9363584 and 9437056.

Dr. Hutton informs us, that thefe three pairs of amicable numbers, with the properties from which they receive their name, were found out by F. Schooten, as appears from Sect. ix. of his *Exercitationes Mathematicæ*. To find the firft pair, he puts $4x$ and $4yz$, or a^2x and a^2yz for the two numbers where $a=2$; then making each of thefe equal to the fum of the aliquot parts of the other, gives two equations, from which are found the values of x and z, and confequently affuming a proper value for y, the two amicable numbers themfelves $4x$ and $4yz$.

In like manner for the other pairs of fuch numbers; in which he finds it neceffary to affume $16x$ and $16yz$, or a^4x and a^4yz for the fecond pair, and $128x$ and $128yz$ or a^7x and a^7yz for the third pair.

Schooten then gives this practical rule, from Defcartes, for finding amicable numbers, viz. affume the number 2, or fome power of the number 2, fuch that if unity or 1 be fubtracted from each of thefe three following quantities, viz. from 3 times the affumed number, alfo from 6 times the affumed number, and from 18 times the fquare of the affumed number, the three remainders may be all prime numbers; then the laft prime number being multiplied by double the affumed number, the product will be one of the amicable numbers fought, and the fum of its aliquot parts will be the other. That is, if a be put = the number 2, and n fome integer number, fuch that $3a^n - 1$, and $6a^n - 1$, and $18a^{2n} - 1$ be all three prime numbers; then is $\overline{18a^{2n} - 1} \times 2a^n$ one of the amicable numbers; and the fum of its aliquot parts is the other.

AMSTERDAM and ST PAUL, are two iflands in the South Sea, lying in the fame degree of longitude, and generally confounded with each other. The Dutch navigators have given the name of *Amfterdam* to the northern, and of *St Paul* to the fouthern ifland, and Captain Cook conforms to that appellation. Moft other Englifh navigators, and particularly Meffrs Cox and Mortimer, with Sir George Staunton, reverfe the names, calling the fouthern ifland Amfterdam, and the other St Paul. At this fouthern ifland the Lion man of war ftopped on her voyage to China with Lord Macartney, the late ambaffador to the court of Pekin, which gave an opportunity to the men of fcience in the train of the ambaffador to examine the ifland with more fkill and attention than probably it had ever been examined before.

Dr Gillan, who was appointed phyfician to the embaffy, as well for his knowledge of chemiftry as for his medical fkill, is confident that the ifland of Amfterdam is the product of fubterraneous fire, as it bears in every part of it evident marks of volcanic eruption. "On the weft and fouth-weft fides (fays he) there are four fmall cones regularly formed, with craters in their centres, in which the lava and other volcanic fubftances have

have every appearance of recent formation. The heat continues ftill fo great, and fuch a quantity of elaftic vapour iffues through numberlefs crevices, that there can be no doubt of their having been very lately in a ftate of eruption. In a thermometer placed upon the furface, the quickfilver rofe conftantly to 180 degrees, and when funk a little into the afhes, it advanced to 212 degrees. It certainly would have rifen ftill higher; but the fcale being graduated only to the point of boiling water, and the length of the tube proportioned to that extent, the thermometer was immediately withdrawn, left the increafing expanfion of the quickfilver fhould burft the glafs. The ground was felt tremulous under the feet; a ftone thrown violently upon it returned a hollow found; and the heat was fo intenfe for a confiderable diftance around, that the foot could not be kept for a quarter of a minute in the fame pofition without being fcorched. But the great crater on the eaftern fide, now full of water, is by far the largeft here, or perhaps elfewhere, and is of an aftonifhing fize, confiderably exceeding in diameter thofe of Etna or Vefuvius. The quantity of matter to be thrown up, which required fo wide an orifice for its paffage, and the force with which fuch matter was impelled, in order to overcome the refiftance of the fuperincumbent earth and fea, muft have been indeed prodigious.

"This vaft crater, according to the ufual method of computing the antiquity of volcanoes, muft have been formed at a very remote period. The lava all around its fides is much decompofed, and has mouldered into duft, which lies on the furface in many parts to a confiderable depth. The decompofition has fupplied a rich foil for the long grafs growing on the fides of the crater, and has even fpread over moft parts of the ifland. The fibrous roots of the grafs, extending in all directions through the decompofed lava and volcanic afhes, and mixed in a decaying ftate with the vegetable mould, produced from the annual putrefaction of the leaves and ftalks, have formed a layer of foil feveral feet deep all over the ifland. But as it has nothing except its own weight to comprefs it together, it is of a light fpongy texture, with very little cohefion, and in many places furrowed and interfected by the fummer rains, and the torrents occafioned by the melting of the fnow which lies upon it in the winter, from three to four feet thick, in all thofe places where the fubterraneous heat is not great enough to prevent its accumulation. In fome parts thefe furrows and cavities are deeper than the level of the common channel; hence they ferve the purpofe of fmall natural refervoirs. The water flows into them from all the neighbouring ground; and as their fides are fhaded, and almoft covered over by the leaves of the long grafs, growing from their edges in oppofite directions, the rays of the fun are excluded, and very little is loft by evaporation. Thefe refervoirs, however, are very fmall, and but few in number; the largeft could not contain more than three or four hogfheads of water; and there is none elfe to be found, except in the fprings on the fides of the large crater.

"The foil everywhere being light and fpongy, and full of holes, formed in it by fea-birds for nefts, is very troublefome to walk upon; the foot breaks through the furface, and finks deep at every ftep; a circumftance which renders the journey acrofs the ifland uncommonly fatiguing, although it be fcarcely three miles from the edge of the great crater to the oppofite weft fide. There is one place near the centre of the ifland, extending about 200 yards in length, and fomewhat lefs in breadth, where particular caution is neceffary in walking over it. From this fpot a hot frefh fpring is fuppofed to derive its fource, finding its way through the interftices of the lava to the great crater, and burfting out a little above the water covering its bottom. The heat in this upper fpot is too great to admit of vegetation. The furface is covered with a kind of mud or pafte formed from the afhes, moiftened by fteam conftantly rifing from below. When the mud is removed, the vapour iffues forth with violence, and in fome parts copioufly. This mud is fo hot, that a gentleman who inadvertently ftepped into it, had his foot feverely fcalded by it. The fame caufes which have prevented vegetation on this fpot, have had the fame effect on the four cones recently thrown up. Their furfaces are covered with afhes only; nor is there the leaft appearance even of mofs on the furrounding lava, for the production of which there does not appear to have elapfed a fufficient length of time fince the cones were formed: but this is not the cafe with the lava of the great primary crater; for in thofe parts of it where the edges are more perpendicular, and where confequently the mouldering decompofed earth, having no bafis to fupport it, flides down the fides of the rock, pretty long mofs was generally found growing upon it. All the fprings or refervoirs of hot water, except one only, were brackifh. One fpring derives its fource from the high ground and ridges of the crater. The water in it, inftead of boiling upwards through the ftones and mud, as in the other fprings, flows downward with a confiderable velocity, in a fmall collected ftream. Its temperature has been found not to exceed 112 degrees. The hand could be eafily kept in it for a confiderable time. It is a pretty ftrong chalybeate. The fides of the rock whence it iffues, and of the cavity into which it falls, are incrufted with ochre depofited from it.

"When the great crater is viewed from the high ground, it appears to have been originally a perfect circle, but to have been encroached upon by the fea on the eaftern fide, where the flood tide ftrikes violently. The rocks of lava which formed the edge of the crater on that fide have fallen down. The depth of the water in the crater is about 170 feet, rendering the whole height of the crater, from the bottom to its upper ridge, nearly if not quite 900 feet. The lofty rocks forming this ridge are the higheft parts of the ifland, which feems to have been originally produced by the melted lava flowing down on all fides from hence. Thus there is a gradual flope from the edges of the crater to the fea; and the lava, though very irregular, and lying in mixed ruin and confufion immediately around the crater, affumes a more uniform appearance at fome diftance, layer refting regularly upon layer, with a gradual declivity the whole way down to the fea. This difpofition of the layers is particularly obfervable in the weft fide, where they happen to terminate in an abrupt precipice. The eruptions that took place at different periods appear here diftinctly marked by the different layers that are found with regular divifions between them; the glaffy lava being undermoft, the compact next, the cellular lava next above, over it the volcanic afhes and lighter fubftances, and a layer of vegetable mould covering the whole."

The ifland appears indeed in fuch a ftate of volcanic inflammation, that from the fhips decks at night were obferved, upon the heights of the ifland, feveral fires iffuing out of the crevices of the earth, more confiderable, but in other refpects refembling fomewhat the nightly flames at Pietra Mala, in the mountains between Florence and Bologna, or thofe near Bradley in Lancafhire, occafioned by fome of the coal-pits having taken fire. In the day nothing more than fmoke could be perceived.

The length of the ifland from north to fouth is upwards of four miles, its breadth from eaft to weft about two miles and a half, and its circumference eleven miles, comprehending a furface of about eight fquare miles, or 5120 acres, almoft the whole of which is covered with a fertile foil. The ifland is inacceffible except on the eaft fide, where the great crater forms a harbour, the entrance to which is deepening annually, and might by the aid of art be made fit for the paffage of large fhips. The tides run in and out at the rate of three miles an hour, and rife perpendicularly eight or nine feet on the full and change of the moon; a northerly wind making the higheft tide. The water is eight or ten fathoms deep clofe to the edge of the crater; and in the bafon formed by the crater itfelf, the variation of the compafs was found to be nineteen degrees and fifty minutes weftward of the north pole.

On the ifland, which has no native inhabitants, were found three Frenchmen and two natives of England, who at the end of the American war had emigrated to Bofton. The whole five had come laft from the Ifle of France in the Indian Ocean, and had been left on the ifland of Amfterdam, about five months before the arrival of the Lion, for the purpofe of procuring a cargo of 25,000 feal-fkins for the Canton market, which, as they had already procured 8000, they hoped to complete in about ten months more. The veffel which brought them from the Ifle of France was gone to Nootka Sound, with a view of bringing a quantity of fea-otter fkins to China; and afterwards of calling for the cargo of feal-fkins at this place, to be carried to China likewife; proceeding thus alternately to Nootka and Amfterdam ifland as long as the owners fhould find their account in it.

The feals, whofe fkins are thus an article of commerce, are found here in greater numbers in the fummer than in the winter, when they generally keep in deep water, and under the weeds, which fhelter them from the inclemency of the weather. In the fummer months they come afhore, fometimes in droves of 800 or 1000 at a time, out of which about 100 are deftroyed, that number being as many as five men can fkin and peg down to dry in the courfe of a day. Little of the oil which thefe animals might furnifh is collected, for want of cafks to put it in; part of the beft is boiled, and ferves thofe people inftead of butter. The feal of Amfterdam is the *phoca urfina* of Linnæus. The female weighs ufually from 70 to 120 pounds, and is from three to five feet in length, but the male is confiderably larger. In general they are not fhy: fometimes they plunge into the water inftantly upon any one's approach, but at other times remain fteadily on the rocks, bark, and rear themfelves up in a menacing pofture; but the blow of a ftick upon the nofe feemed fufficient to difpatch them. As the fkins alone were the objects wanted, the carcafes were left on the ground to putrify at leifure, ftrewed in fuch numbers as to render it difficult to avoid treading on them in walking along. The people thus employed were remarkable for the fqualor and filth of their perfons, clothes, and dwelling; yet none of them feemed defirous of leaving the place before the bufinefs they came upon fhould be completed. One of them, an Englifhman, who had been a confiderable time upon the ifland on a former adventure, gave but an unfavourable account of the weather during the winter months, which are always boifterous, with hail and fnow; but in fummer he acknowledged it to be very fine.

The fea fupplies this ifland with great varieties of excellent fifh, particularly a kind of cod, which was equally relifhed whether frefh or falted. Cray fifh were in fuch abundance on the bar acrofs the entrance into the crater, that at low water they might be taken with the hand; and at the anchorage of the fhips, when bafkets, in which were proper baits, were let down into the fea, they were in a few minutes drawn up filled with cray fifh. This circumftance is the more extraordinary, that in the fame place were found abundance of fharks and dog fifh of uncommon fize, which are known to be fo voracious and fuch enemies to all other fifh. The bafon of the crater abounds with tench, bream, and perch; and the perfon who with a hook and line has caught any of thefe fifh in the cold water of the bafon, may with a flight motion of his hand let them drop into the adjoining hot fpring already mentioned, in which they will be boiled and rendered fit for eating in the fpace of fifteen minutes. This was often practifed by the gentlemen of the embaffy, and furnifhed them at once with a fingular amufement and a highly relifhed repaft.

Of all the birds which frequent this ifland, fo extraordinary in its origin, formation, and appearance, not one is common to the fame degree of latitude in the northern hemifphere. Of the larger kind were feveral fpecies of the *albatrofs*; on examining one of which, diftinguifhed by the name of *exulans*, it was found, that inftead of having only the rudiments of a tongue, as naturalifts generally fuppofe, it had one equalling half the length of the bill. Another large bird is likewife common here, called the great *black petrel*, or *procellaria equinoctialis* of Linnæus. It is the determined enemy of the albatrofs, as well as of the *blue petrel* of Amfterdam, or *procellaria forfteri*. This blue petrel, which is about the fize of a pigeon, conftitutes the principal food of the feal-catchers on the ifland. During the day-time they hide themfelves in the ground, in order to efcape, if poffible, their deftroyer the black petrel. At night they come abroad, and thence are termed *night birds* by the people at Amfterdam; but being fond of flocking to any light, they fall into another fnare laid for them by the feal-catchers, who kindle torches to attract them, and then kill them in multitudes. The pretieft of the feathered tribe, inhabiting or vifiting Amfterdam, is the filver bird, or *fterna hirundo*, about the fize of a large fwallow or fwift, with a forked or fwallow tail. The bill and legs are of a bright crimfon colour, the belly white, and the back and wings of a bluifh afh colour. This bird fubfifts chiefly on fmall fifh, which it it picks up as they are swimming over the surface of the water.

This singular island lies in 38° 42′ S. Lat. and in 76° 54′ E. Long. from Greenwich. St Paul's, or the island lying in sight and to the northward, differed in appearance materially from Amsterdam. It presented no very high land, or any rising in a conic form; and seemed to be overspread with shrubs or trees of a middling size. It was said to abound with fresh water, but to have no good anchorage near it, nor any place of easy landing.—*Sir George Staunton's Account of an Embassy to the Emperor of China.*

AMELINS, *Ecor a*, is a south eastern head branch of Wabash river, whose mouth is 9 miles N. E. from the mouth of Salamanie river, and 45 miles S. W. from the Miami village and fort.—*Morse.*

AMOENIA, a thriving township in Dutchess county, New-York, 6 miles distant from Sharon, in Connecticut. It contains 3078 inhabitants, of whom 383 are electors.—*ib.*

AMHERST, a township in Cumberland county, Nova-Scotia, situated on Chignecto Bason, on the S. side of La Planch River, and on the rivers Napan and Macon. The navigation of the two last is difficult on account of shoals. The town was settled by North Irish, Yorkshire and New-England people.—*ib.*

Amherst, the shire-town of Hillsborough county, New-Hampshire, is a town of some note, formerly *Souhegan West*, and was originally granted from *Massachusetts*. It has 2369 inhabitants, and was incorporated in 1762. The Aurean Academy was founded here in 1790. A few years ago, the township being much infested with wolves, the people, on a day appointed, surrounded a large swamp which they frequented, and kept up an incessant firing of guns and beating of drums the whole day; which music forced the wolves to decamp the following night, with dismal howlings; and they have never done any mischief in the town since. Amherst lies on a northern branch of Souhegan River, which falls into Merrimack River, and is 60 miles W. of Portsmouth, and 53 N. W. of Boston. N. lat. 42. 54. W. long. 71. 33.—*ib.*

Amherst, a township in Hampshire county, Massachusetts, containing 1233 inhabitants; 91 miles westerly from Boston, and about eight north-easterly from Northampton.—*ib.*

Amherst *County*, in Virginia, lies between the Blue Ridge and the tide waters, and contains 13,703 inhabitants, including 5296 slaves. It lies on the north of James River.—*ib.*

AMICU, a lake in the province of Cumana, South-America, whose waters run southwardly through Parima River into the Amazon.—*ib.*

AMONOOSUCK, an Indian name given to two rivers in New-Hampshire: the one is called *Upper* Amonoosuck, passing through a tract of excellent meadow. It rises near the north end of the White Hills, runs northerly about 15 miles, where is a carrying place of about three miles to Amariscoggin River. From thence the river runs S. W. and W. nearly 18 miles, and empties into the Connecticut at Northumberland, near the Upper Coos.

The other is called *Great* or *Lower* Amonoosuck, which rises on the west side of the White Mountains. It falls into the Connecticut just above the town of Haverhill, in Lower Coos, by a mouth 100 yards wide. About two miles from its mouth it receives *Wild Amonoosuck*, 40 yards wide from Franconia and Lincoln Mountains. Two or three hours rain raises the water in this last mentioned river several feet, and occasions a current so furious as to put in motion stones of a foot in diameter, but its violence soon subsides.—*ib.*

AMOTAPE, a town near Tumbez, lying near the shore of the South Sea, in the empire of Peru. Being near a river of fine water, the adjacent country is highly improved. Lat. 4. 15. 43. S.—*ib.*

AMPALLA, by some authors called *Ampalia*, a city and seaport in Guatimala Gulf, in that of Mexico, 350 miles S. E. of the city of Guatimala, and carries on a brisk trade in cochineal, cocoa, hides, indigo, &c.—*ib.*

AMPARES, a jurisdiction under the archbishop of Plata, eastward of that city, in the empire of Peru. It abounds in grain and cattle.—*ib.*

AMUSKEAG *Falls*, in New-Hampshire, are on Merrimack River, sixteen miles below Concord, and seven below Hookset Falls. It consists of three pitches, one below the other, so that the water falls about 80 feet in the course of half a mile. The second pitch, which may be seen from the road, on the W. side, is truly majestic. In the middle of the upper part of the fall is a high rocky island, on the top of which are a number of pits, made exactly round, like barrels or hogsheads, some of which are capable of holding several tons; formed by the circular motion of small stones, impelled by the force of the descending water. There is a bridge across the falls 556 feet in length, and 20 in breadth, consisting of 2000 tons of timber, and made passable for travellers 57 days after it was begun. N. lat. 42. 59.—*ib.*

ANACLASTIC curves, a name given by M. de Mairan to certain apparent curves formed at the bottom of a vessel full of water, to an eye placed in the air; or the vault of the heavens, seen by refraction through the atmosphere.

ANAPHORA, in astrology, the second house, or that part of the heavens which is 30 degrees from the horoscope. The term *anaphora* is also sometimes applied promiscuously to some of the succeeding houses, as the 5th, the 8th, and the 11th. In this sense *anaphora* is the same as *epanaphora*, and stands opposed to *cataphora*.

ANASTATIA, St. a small island close to the coast of East-Florida, situated S. of Mastances Inlet, where the river Mastances forms two islands of the same name at its mouth. St. Anastatia island is bounded on the N. by St. Augustine's bar. Here is a quarry of fine stone for building.

ANASTROUS signs, in astronomy, a name given to the *duodecatemoria*, or the twelve portions of the ecliptic, which the signs possessed anciently, but have since deserted by the precession of the equinox.

ANCHOR of a ship, is an instrument which, as it is commonly made, has been sufficiently described in the Encyclopædia. An improvement, however, has been proposed on its construction by Mr James Stu nd of the parish of St Anne, Middlesex, who obtained a patent for his invention, dated Feb. 9, 1796.

The whole of this invention consists in making the anchor

anchor with one fluke or arm inſtead of two, and contriving to load that fluke or arm in ſuch a manner as to make it always fall the right way. With this view Mr Stuard would have the ſhank of the anchor made very ſhort, that it may *cant* the more when ſuſpended by the cable; and he would have the arm and it made of bars in one length, that there may be no ſhoot or joining in the whole inſtrument. The bend of the ſhank and arm he would have rounded, and not angular as in the common anchor; and on this bend he would have a ſmall ſhackle, or two plates with a ſmall bolt between them, for the buoy rope to be made faſt to. Inſtead of wood. he propoſes for the ſtock of the anchor a bar of wrought iron, loaded or covered at the ends with knobs of caſt iron; and he would have the palm of the fluke or arm either to be compoſed entirely of caſt iron, or to be a caſt iron ſhell filled with lead. This weight of the palm, the ſhortneſs of the ſhank, and the ſtructure of the ſtock, will no doubt make the anchor fall the right way; which, having no upper fluke, will never be tripped by the cable taking hold of it on the ſhip's ſwinging, nor will it prove ſo dangerous as the common anchor to ſuch veſſels as may happen to ground by it.

ANCOCUS or RANCOCUS *Creek*, in New-Jerſey, a water of the Delaware, 6 miles S. W. from Burlington. It is navigable 16 miles; and conſiderable quantities of lumber are exported from it—*Morſe*.

ANDAGUAYLAS, a juriſdiction in South-America, in the empire of Peru, ſubject to the archbiſhop of Lima; lying E. by S. of the city of Guamanga. It abounds in ſugar plantations, grain of moſt ſorts, and fruits.—*ib*.

ANDERSON (Alexander), an eminent mathematician, was born at Aberdeen towards the end of the 16th century Where he was educated, or under what maſters, we have not learned; probably he ſtudied the belles lettres and philoſophy in the univerſity of his native city, and, as was the practice in that age of all who could afford it, went afterwards abroad for the cultivation of other branches of ſcience. But wherever he may have ſtudied, his progreſs in ſcience muſt have been rapid; for, early in the 17th century, we find him profeſſor of mathematics in the univerſity of Paris, where he publiſhed ſeveral ingenious works; and among others, 1. *Supplementum Apollonii Redivivi; ſive analyſis problematis hactenus deſiderati ad Appollonii Pergæi doctrinam* περι νευσεων, *a Marino Ghetaldo Patritio Raguſino hujuſque, non ita pridem reſtitutam. In qua exhibetur mechanice æqualitatum tertii gradus ſive ſolidarum, in quibus magnitudo omnino data, æquatur homogeneæ ſub altero tantum coefficiente ignoto. Huic ſubnexa eſt variorum problematum practice*, Paris, 1612, *in* 4to.—2. Απολογια: *Pro Zetetico Apolloniani problematis a ſe jam pridem edito in ſupplemento Apollonii Redivivi. Ad clariſſimum et ornatiſſimum virum Marinum Ghetaldum Patritium Raguſinum. In qua ad ea quæ obiter mihi perſtrinxit Ghetaldus reſpondetur, et analytice clarius detegitur*. Paris, 1615, in 4to.—3. *Franciſci Vietæ Fontenacenſis de Æquationum Recognitione et Emendatione Tractatus duo*, with a dedication, preface, and appendix, by himſelf. Paris, 1615, in 4to.—4. Vieta's *Angulares Sectiones;* to which he added demonſtrations of his own. Our profeſſor was couſin german to Mr David Anderſon of Finſhaugh, a gentleman who alſo poſſeſſed a ſingular turn for mathematical knowledge. This mathematical genius was hereditary in the family of the Anderſons; and from them it ſeems to have been tranſmitted to their deſcendants of the name of Gregory, who have for ſo many generations been eminent in Scotland as profeſſors either of mathematics, or, more lately, of the theory and practice of phyſic. The daughter of the David Anderſon juſt mentioned, was the mother of the celebrated James Gregory, inventor of the reflecting teleſcope; and obſerving in her ſon, while yet a child, a ſtrong propenſity to mathematical ſtudies, ſhe inſtructed him in the elements of that ſcience herſelf. From the ſame lady deſcended the late Dr Reid of Glaſgow, who was not leſs eminent for his knowledge of mathematics than for his writings as a metaphyſician.

The preciſe dates of Alexander Anderſon's birth and death, we have not learned either from Dempſter, Mackenzie, or Dr Hutton, who ſeems to have uſed every endeavour to procure information; nor are ſuch of his relations as we have had an opportunity of conſulting, ſo well acquainted with his private hiſtory as we expected to find them.

ANDOVER, a large, fertile and thriving town in Eſſex county, Maſſachuſetts. It contains 2863 inhabitants, in two pariſhes. In the South pariſh are a paper mill and powder mill, from the latter of which the army received large ſupplies of gun-powder in the late war. There is an excellent academy in this town, called "Phillips Academy," which owes its exiſtence to the liberal benefactions of the family whoſe name it bears. Andover is under excellent cultivation, particularly that part which is watered by Shawſheen River. It lies about 20 miles W. from Newburyport, and about 22 N. from Boſton.—*Morſe*.

ANDOVER, in Hillſborough, New-Hampſhire, contains 645 inhabitants, and was incorporated in 1779. —*ib*.

ANDOVER, is the ſouth-weſternmoſt townſhip in Windſor county, Vermont, has Cheſter on the E. lies 32 miles N. E. of Bennington, and contains 275 inhabitants.—*ib*.

ANDOVER, a place in Suſſex county, New-Jerſey, near the ſource of Pequeſt river, 5 miles S. E. from New-Town, and 16 in the ſame direction from Walpack.—*ib*.

ANDREW's, ST. a ſmall town in the conteſted country between New-Brunſwick and the United States; ſituated in the rear of an iſland of the ſame name, on the E. ſide of the arm of the inner bay of Paſſamaquoddy, called Scoodick. The town is regularly laid out in the form of an oblong ſquare. The few inhabitants are chiefly employed in the lumber trade. The common tide riſes here about 18 feet.—*ib*.

ANDREW's, ST. a townſhip in Caledonia county, Vermont, 100 miles N. E from Bennington.—*ib*.

ANDREW's, ST. a pariſh in Charleſton diſtrict, South Carolina, containing 2947 inhabitants, of whom 370 are whites and 2546 ſlaves.—*ib*.

ANDREW's SOUND, ST. lies S. of Jekyl's Iſland, and is formed by it and a ſmall iſland at the mouth of Great Satilla river. The ſmall river oppoſite this ſound ſeparates Camden from Glynn county, in Georgia.—*ib*.

ANDROSCOGGIN, or *Amariſcoggin river*, in the diſtrict of Maine, may be called the main weſtern branch of the Kennebeck. Its ſources are N. of Lake

Umbagog.

Umbagog. Its courſe is ſoutherly till it approaches near to the White Mountains, from which it receives Mooſe and Peabody rivers. It then turns to the E. and then to the S. E. in which courſe it paſſes within two miles of the ſea-coaſt, and then turning N. runs over Pejepſkaeg falls into Merry-Meeting-Bay, where it forms a junction with the Kennebeck, 20 miles from the ſea. Formerly, from this bay to the ſea, the confluent ſtream was called Sagadahock. The lands on this river are very good.—*Morse.*

ANEGADA, one of the Virgin Iſles in the Weſt-Indies, and dependent on Virgin Gorda. It is about 6 leagues long, is low, and almoſt covered by water at high tides. On the S. ſide is Treaſure point. Lat. 18. 35. N. long. 63. W.—*ib.*

ANGARAEZ, a province in South-America, in the empire of Peru, ſubject to the archbiſhop of Lima, 20 leagues N. W. by W. of the city of Guamanga. It abounds in all kinds of grain and fruits, beſides vaſt droves of cattle for labour and ſuſtenance.—*ib.*

ANGUILLA, a bank and iſland E. of the Great Bahama Bank, and N. of the iſland of Cuba. Long. 78. 10. to 79½. lat. 23½. to 24. 10. N.—*ib.*

ANGUILLE, Cape, a point of land in Newfoundland iſland, on the W. ſide, in the Gulf of St. Lawrence, 6 leagues N. from Cape-Ray, the S. W. extremity of the iſland, in lat. 47. 57. N.—*ib.*

Anguille, a bay on the N. N. E. ſide of the iſland of St. John's, in the Gulf of St. Lawrence, oppoſite Magdalen Iſles; and having St. Peter's harbour on the S. E. and Port Chimene on the N. W. —*ib.*

ANHINGA, in ornithology, a ſpecies of the pelicanus; conſiſts of four known varieties, two peculiar to America, one to Senegal, and the fourth to the region about the Cape of Good Hope. This laſt is thus deſcribed by Le Vaillant in his New Travels into the Interior Parts of Africa.

" The denomination of *Slange-Hals-Voogel*, given to it by the Hottentots, characteriſes the anhinga in a very ſimple and accurate manner. Buffon, who was ſtruck with the conformation peculiar to birds of this kind, has delineated them by a ſimilar expreſſion. Plate III. 'The anhinga (ſays he) exhibits a reptile grafted on the body of a bird.' Indeed there is no perſon who, upon ſeeing the head and neck only of an anhinga, while the reſt of the body is hid among the foliage of the tree on which it is perched, would not take it for one of thoſe ſerpents accuſtomed to climb and reſide in trees; and the miſtake is ſo much the eaſier, as all its tortuous motions ſingularly favour the illuſion. In whatever ſituation the anhinga may be ſeen, whether perched on a tree, ſwimming in the water, or flying in the air, the moſt apparent and remarkable part of its body is ſure to be its long and ſlender neck, which is continually agitated by an oſcillatory motion, unleſs in its flight, when it becomes immoveable and extended, and forms with its tail a perfectly ſtraight and horizontal line.

" The true place which nature ſeems to have aſſigned to the anhingas, in the numerous claſs of the palmipedes, is exactly between the cormorant and the grebe. They partake indeed equally of both theſe genera of birds, having the ſtraight ſlender bill and the long neck of the latter; while they approach the former by the conformity of their feet, the four toes of which are joined by a ſingle membrane. They partake alſo of the cormorant by their flight; having like it the wings larger and fitter for the purpoſe than thoſe of the grebe, which are ſhort and weak. The tail of the anhinga is extremely long; a characteriſtic very ſingular and remarkable in a water fowl, and which ought, it would ſeem, to render them totally diſtinct from diving birds, which in general have little or no tail. By this trait they approach ſtill nearer to the cormorants; for tho' the tails of the latter are ſhorter, the tails of both have a great reſemblance to each other, ſince their quills are equally ſtrong, elaſtic, and proper to form a rudder when theſe fowls ſwim through the water in purſuit of fiſh, which conſtitute their principal nouriſhment. When the anhinga ſeizes a fiſh, he ſwallows it entire if it be ſmall enough, and if too large he carries it off to a rock or the ſtump of a tree, and fixing it under one of his feet, tears it to pieces with his bill.

" Though water is the favourite element of this bird, it builds its neſt and rears its young on rocks and trees; but it takes great care to place them in ſuch a manner, that it can precipitate them into a river as ſoon as they are able to ſwim, or the ſafety of the little family may require it.

The male anhinga differs from the female, which is ſmaller, in having the whole under part of the body, from the breaſt to the root of the tail, of a beautiful black, while the latter has the ſame parts of a yellow iſabella colour. It has alſo, on each ſide of its neck, a white ſtripe, which extends from the eye to the middle of its length, and interſects a reddiſh ground. A very ſingular characteriſtic, common to all the anhingas, is that of having the feathers of the tail deeply ſtriated, and as it were ribbed. It is a very ſagacious bird, eſpecially when ſurpriſed ſwimming; for its head is the only part which it expoſes above the water; and if the ſportſman once miſs that part, the anhinga plunges out of ſight entirely, and never more ſhows itſelf but at very great diſtances, and then no longer at a time than is abſolutely neceſſary for breathing.

ANNAPOLIS *River*, in Nova-Scotia, is of ſmall ſize. It riſes in the E. near the head waters of the ſmall rivers which fall into the baſon of Minas. Annapolis river paſſes into the bay of Fundy through the baſon of its own name, in the S. ſide of which, at the mouth of the river, ſtands the town and fort of Annapolis Royal. It is navigable for ſhips of any burden 10 miles, for thoſe of 100 tons, 15 miles; and is paſſable for boats within 20 miles of Horton. The tide flows up 30 miles.—*Morse.*

Annapolis, a county on the above river, adjoining to King's county, having 5 townſhips, viz. Wilmot, Granville, Annapolis, the chief towns, Clare, and Monckton. It is chiefly inhabited by Acadians, Iriſh, and New-Englanders.—*ib.*

ANN ARUNDEL *County*, in Maryland, lies between Patapſco and Patuxent Rivers, and has Cheſapeak Bay S. E. Annapolis is the chief town. This county contains 22,598 inhabitants, of whom 10,131 are ſlaves.—*ib.*

ANN, Cape, is the point of land in the town of that name, or Glouceſter, which forms the N. ſide of Maſſachuſetts Bay, as Cape Cod does the S. ſide. N. lat. 42. 45. long. 70. 17. W. See *Glouceſter*. This

Cape was so named in honour of Ann, consort of King James I.—*ib.*

ANN, St. a lake in Upper Canada, northerly from Lake Superior, which sends its waters north-easterly into James's Bay, through Albany River. Its north-eastern point lies in N. lat. 50. W. long. 88.—*ib.*

ANN, St. is the chief town of the province of Parana, in the E. division of Paraguay, South America.—*ib.*

ANN's, St. a port on the E. side of Cape Breton Island, where fishing vessels often put in. It lies on the N. W. side of the entrance into Labrador Lake. W. long. 60. N. lat. 47.—*ib.*

ANN's, St. is a small town on the River St. John's, province of New-Brunswick, about 80 miles from St. John's. It is at present the seat of government.—*ib.*

ANN, Fort, in the state of New-York, lies at the head of batteaux navigation, on Wood Creek, which falls into South Bay, Lake Champlain, near Skenesborough. It lies 6½ miles S. W. by S. from Skenesborough Fort; 10 E. S. E. from Fort George, and 12 N. E. by N. from Fort-Edward, on Hudson River. Such was the savage state of this part of the country, and the layers of trees laid lengthwise and across, and so broken with creeks and marshes, that General Burgoyne's army, in July, 1777, could scarcely advance above a mile in a day, on the road to Fort-Edward. They had no fewer than 40 bridges to construct, one of which was of log work 2 miles in length; circumstances which in after ages will appear hardly credible.—*ib.*

ANSON, an interior county of N. Carolina, in Fayette district, having Mecklinburg county N. and Bladen and Cumberland counties on the E. It contains 5133 inhabitants, including 828 slaves.—*ib.*

ANTECEDENTAL calculus. See Calculus in this Supplement.

ANTES, in architecture, small pilastres placed at the corners of buildings.

ANTHONY's Falls, St. in the River Mississippi, lie about 10 miles N. W. of the mouth of St. Pierre River, which joins the Mississippi from the W. and are situated in about lat. 44. 50. N. and were so named by father Louis Hennipin, who travelled into these parts about the year 1680, and was the first European ever seen by the natives there. The whole river, 250 yards wide, falls perpendicularly above 30 feet, and forms a most pleasing cataract. The rapids below, in the space of 300 yards, render the descent considerably greater; so that when viewed at a distance, they appear to be much higher than they really are. In the middle of the falls is a small island, about 40 feet broad, and somewhat longer, on which grow a few hemlock and spruce trees; and about half way between this island and the eastern shore, is a rock, lying at the very edge of the fall, in an oblique position, 5 or 6 feet broad, and 30 or 40 long. These falls are peculiarly situated, as they are approachable without the least obstruction from any intervening hill or precipice; which cannot be said, perhaps, of any other considerable fall in the world. The scene around is exceedingly beautiful. It is not an uninterrupted plain, where the eye finds no relief, but composed of many gentle ascents, which, in the spring and summer, are covered with verdure, and interspersed with little groves, that give a pleasing variety to the prospect.

At a little distance below the falls is a small island, about 1½ acre, on which grow a great number of oak trees, all the branches of which, able to bear the weight, are, in the proper season of the year, loaded with eagles nests. Their instinctive wisdom has taught them to choose this place, as it is secure, on account of the rapids above, from the attacks either of man or beast.—*Morse.*

Anthony's *Kill*, a western water of Hudson River. Its mouth is 7 miles above that of Mohawk River, with which likewise it communicates at the E. end of Long Lake.—*ib.*

Anthony's *Nose*, a point of land in the Highlands, on Hudson River, in the state of New-York, from which to Fort Montgomery on the opposite side, a large boom and chain was extended in the late war, which cost not less than 70,000l. sterling. It was partly destroyed and partly carried away by General Sir Henry Clinton, in October, 1777. Also, the name given to the point of a mountain on the N. bank of Mohawk River, about 30 miles above Schenectady. Around this point runs the stage road.—*ib.*

ANTICS, in architecture, figures of men and animals placed as ornaments to buildings.

ANTICUM, in architecture, a porch; also that part of a temple which lies between the body of the temple and the portico, and is therefore called the outer temple.

ANTIETAM *Creek*, in Maryland, rises by several branches in Pennsylvania, and empties into Potowmack River, 3 miles S. S. E. from Sharpsburg. Elizabeth and Funk's towns stand on this creek. It has a number of mills and forges.—*Morse.*

ANTIMETER, or Reflecting Sector, an instrument invented by Mr William Garrard, for the purpose of measuring angles, particularly small ones, with a greater degree of accuracy than can be done by Hadley's quadrant or by the sextant.

The frame of this instrument is similar to that of Hadley's quadrant, having two radii, a limb, and braces; but with this difference, that the further radius is produced upwards of four inches beyond the centre of motion of the index; and the great speculum, or what is called the index-glass in Hadley's quadrant, being placed there, is called the *upper centre*. In this instrument there is no provision for the back observation. The horizon-glass is like that in Hadley's quadrant; there are two sight vanes, to suit two different situations of the large speculum or object glass: these vanes are adapted to receive a small telescope. On the centre of the index, where the index glass of Hadley's quadrant is fixed, is a brass or bell-metal semicircle, two inches in diameter, and one eighth of an inch thick: this semicircle is screwed fast to the index, in such a manner that the axis of the index is a tangent to it. On the upper centre are two circular brass plates, which revolve concentrically, either together or separately. The under plate has a lever, or part perpendicular to the plane of the instrument, projecting downwards, a little beyond the lower centre: this lever is acted upon by the semicircular plate at the lower centre, to which it is always kept close by a spring on the other side. In the upper of the above mentioned circular plates are two

two circular perforations or slits, through one of which a screw takes into the head of the instrument, and thro' the other a screw takes into the lower moveable plate. The large speculum is fastened to the upper plate; and by the above mentioned screws the position of this glass may be altered. A circular plate is fixed to the lower centre by three pillars: in its centre is a nut to admit a screw, by which the plate carrying the large speculum may be fastened here occasionally.

The scale on the limb is divided into 45 equal parts or degrees, and not into half degrees as is the case in Hadley's quadrant, by reason of the double reflection. These divisions are numbered in a retrogade order; zero being at the extremity of the further radius. Although the limb contains 45 degrees, yet the greatest angle which can be measured, the large speculum remaining fixed to the circular plate, is $10^{\circ} 18' 21''.8$; the distance between the two centres being four inches, and the radius of the semicircle one inch. Agreeable to these dimensions, the inventor has given a table exhibiting the value of each primary division on the limb; he hath also given a more ample table, adapted to a distance between the centres of three times the radius of the semicircle, which he says hath been found the most convenient in practice. If an angle greater than $10^{\circ} 18'$ is wanted, it may be measured by the method of *anticipation*, as the inventor calls it, which is as follows: Let the screw which fastens the two circular plates on the upper centre be made fast, and loosen the screw which fastens the upper circular plate to the instrument: Now adjust the glasses by the usual method; bring forward the index to any given division on the limb, and make it fast; also fasten the screw which was before loose, and loosen the other screw; then bring the index to zero, and proceed as before.

The inventor gives the following directions for adjusting and using the instrument.

The first thing to be attended to is, to set the horizon-glass perpendicular to the plane of the instrument, which is performed as follows: Hold the instrument with its plane perpendicular to the horizon, and look over backwards into the glass and beyond it. If the limb of the instrument appears in a right line with its reflection, the glass is upright; but if it does not appear so, loosen or tighten the little screw on the foot of the glass until it be adjusted: Then with the instrument, as in taking an altitude, look through the sight vane or telescope at some distant object, with the index fixed in any intended situation; the two screws at the upper centre being loose, turn the glass about till the same object appears nearly in the same part of the horizon-glass: Next hold it in a horizontal position, and adjust the object-glass or large speculum with the screws which are behind and before, on the foot of it, till the object and its reflection are seen in the same horizontal line. Lastly, with the instrument upright, turn the tangent-screw belonging to the horizon-glass at the back of the instrument, until there be a perfect coincidence of the object and its reflection that way, and the adjustments are complete.

ANTIPARALLELS, in geometry, are those lines which make equal angles with two other lines, but contrary ways; that is, calling the former pair the first and second lines, and the latter pair the third and fourth lines, if the angle made by the first and third lines be equal to the angle made by the second and fourth, and contrariwise the angle made by the first and fourth equal to the angle made by the second and third; then each pair of lines are antiparallels with respect to each other, viz. the first and second, and the third and fourth. So, if AB and AC be any two lines, and FC and FE be two others, cutting them so, Plate II. fig. 5.

that the angle B is equal to the angle E,
and the angle C is equal to the angle D;

then BC and DE are antiparallels with respect to AB and AC; also these latter are antiparallels with regard to the two former. It is a property of these lines, that each pair cuts the other into proportional segments, taking them alternately,

viz. AB : AC : : AE : AD : : DB : EC,
and FE : FC : : FB : FD : : DE : BC.

ANTONIO DE SUCHITEPEC, ST. a town in Mexico or New Spain, on the coast of the Pacific Ocean. N. lat. 15. W. long. 93 5.—*Morse.*

ANTONIO, ST. the capital of the province of Apachiera, in New-Mexico.—*ib.*

ANTONIO, a town in the province of Navarre, in North-America, on a river which runs S. W. into the Gulph of California.—*ib.*

ANTONIO, CAPE ST. the most western point of the island of Cuba; having on the N. W. a number of islets and rocks, called Los Colorados, between which and the cape is the channel of Guaniguanica. N. lat. 22. 15. W. long. $85\frac{1}{2}$.—*ib.*

ANTONIO DE CABO, ST. a town in Brazil, in South-America, near Cape St. Augustine, subject to the Portuguese. Here they make a considerable quantity of sugar. S. lat. 8. 34. W. long. 35. 22.—*ib.*

ANTONIO ST. a town in New-Mexico, on the W. side of Rio Bravo River, below St. Gregoria. Also, the name of a town on the river Hondo, which falls into the Gulf of Mexico, N. E. of Rio de Brava; and on the eastern side of the river, S. by W. from Texas.—*ib.*

ANTERIM, a township in Hillsborough county, New-Hampshire, having 528 inhabitants, incorporated in 1777; 75 miles W. of Portsmouth, and about the same distance N. W. of Boston.—*ib.*

ANVILLE, or *Miller's Town*, in Dauphine county, Pennsylvania, at the head of Tulpehocken Creek. When the canal between the Susquehannah and Schuylkill, along these creeks, is completed, this town will probably rise to some consequence. It lies 18 miles N. E. by E. from Harrisburg, and 65. N. W. from Philadelphia.—*ib.*

ANZERMA, is a town and province of Popayan, in South-America, having mines of gold. It is seated on the river Coca. N. lat. 4. 58.—*ib.*

APACHIERA, an audience and province of New-Mexico, whose capital is St. Fe, in N. lat. 36. 30. W. long. 104.—*ib.*

APALACHES or *St. Mark's R.* rises in the country of the Seminole Indians, in E. Florida, in N. lat. 31. 30. near the N. W. source of Great Satilla River; runs S. W through the Apalachy country, into the bay of Apalachy, in the Gulph of Mexico, about 15 miles below St. Mark's. It runs about 135 miles, and falls into the Bay near the mouth of Apalachicola River.—*ib.*

APALACHICOLA, a river between E. and W.

Florida, having its source in the Apalachian Mountains, in the Cherokee country, within ten miles of Tugaloo, the upper branch of Savannah River. From its source to the mouth of Flint River, a distance of 300 miles, it is called Chata-Uche, or Chatahooche River. Flint River falls into it from the N. E. below the Lower Creek Towns, in N. lat. 31. From thence it runs near 80 miles and falls into the Bay of Apalachy, or Apalachicola, in the Gulf of Mexico, at Cape Blaize. From its source to the 33d deg. of N. lat. its course is S. W. from thence to its mouth it runs nearly S. See *Chata-Ucha* and *Flint Rivers*.—*ib.*

Apalachicola, is likewise the name of the mother town or capital of the Creek or Muscogulge confederacy, called Apalachucla by Bartram. It is, says he, sacred to peace; no captives are put to death or human blood spilt here: and when a general peace is proposed, deputies from all the towns in the confederacy meet here to deliberate. On the other hand, the great Coweta Town, 12 miles higher up the Chata-Uche River, is called the *Bloody Town*, where the Micos chiefs and warriors assemble when a general war is proposed; and there captives and state malefactors are put to death. Apalachicola is situated a mile and an half above the ancient town of that name, which was situated on a peninsula formed by the doubling of the river, but deserted on account of inundations. The town is about 3 days journey from Tallassee, a town on the Tallapoose River, a branch of the Mobile River. See *Coweta*, and *Tallassee*.—*ib.*

APALACHY *Country*, extends across Flint and Apalaches Rivers, in East Florida, having the Seminole country on the N. E. Apalachy, or Apalachya, is by some writers, applied to a town and harbour in Florida, 90 miles E. of Pensacola, and the same distance W. from Del Spiritu Santo River. The tribes of the Apalachian Indians lie around it.—*ib.*

APERTURE, in optics, has been defined in the Encyclopædia, but no rule was given there for finding a just aperture. As much depends upon this circumstance, our optical readers will be pleased with the following practical rule given by Dr Hutton in his Mathematical Dictionary. "Apply several circles of dark paper, of various sizes, upon the face of the glass, from the breadth of a straw to such as leave only a small hole in the glass; and with each of these, separately, view some distant object, as the moon, stars, &c. then that aperture is to be chosen through which they appear the most distinctly.

"Huygens first found the use of apertures to conduce much to the perfection of telescopes; and he found by experience (*Diopt.* prop. 56.), that the best aperture for an object-glass, for example of 30 feet, is to be determined by this proportion, as 30 to 3, so is the square root of 30 times the distance of the focus of any lens to its proper aperture: and that the focal distances of the eye-glasses are proportioned to the apertures. And M. Auzout says he found, by experience, that the apertures of telescopes ought to be nearly in the subduplicate ratio of their lengths. It has also been found by experience, that object-glasses will admit of greater apertures, if the tubes be blacked within side, and their passage furnished with wooden rings.

"It is to be noted, that the greater or less aperture of an object-glass, does not increase or diminish the visible area of the object; all that is effected by this is the admittance of more or fewer rays, and consequently the more or less bright the appearance of the object. But the largeness of the aperture or focal distance causes the irregularity of its refractions. Hence, in viewing Venus through a telescope, a much less aperture is to be used than for the moon, or Jupiter, or Saturn, because her light is so bright and glaring. And this circumstance somewhat invalidates and disturbs Azout's proportion, as is shown by Dr Hook, Phil. Trans. N° 4."

APOCATASTASIS, or, as it should be written, Apokatastasis, is a Greek word employed in the language of astronomers, to denote the period of a planet, or the time it takes to return to that point of the zodiac whence it set out.

APOQUENEMY *Creek*, falls into Delaware Bay from Middletown, in New-castle county, Delaware, a mile and an half below Reedy Island. A canal is proposed to extend from the southern branch of this creek, at about 4 miles from Middletown, to the head of Bohemia River, nearly 8 miles distant; which will form a water communication between Delaware Bay, and that of Chesapeak, through Elk River.—*ib.*

APPLE *Island*, a small uninhabited island in St. Lawrence River, in Canada, on the S. side of the river, between Basque and Green Islands. It is surrounded by rocks, which renders the navigation dangerous.—*ib.*

Apple *Town*, an Indian village on the E. side of Seneca Lake, in New-York, between the townships of Ovid on the S. and Romulus on the N.—*ib.*

APPOMATOX, is the name of a southern branch of James River, in Virginia. It may be navigated as far as Broadways, 8 or 10 miles from Bermuda Hundred, by any vessel which has crossed Harrison's Bar, in James River. It has 8 or 9 feet water a mile or two farther up to Fisher's Bar, and 4 feet on that and upwards to Petersburg, where all navigation ceases.—*ib.*

APOLO BAMA, a jurisdiction consisting of missions belonging to the Franciscans, subject to the bishop of Cusco, 60 leagues from that city, in the empire of Peru. These consist of 7 towns of converted Indians. To protect these from the insults of the other Indians, and to give credit to the missionaries, a militia is kept here, under a major-general, formed by the inhabitants.—*ib.*

APOTOME, is a term employed by Euclid to denote the difference between two lines or quantities which are only commensurable in power. Such is the difference between 1 and $\sqrt{2}$, or the difference between the side of a square and its diagonal. The doctrine of apotomes in lines, as delivered by this ancient mathematician in the tenth book of his Elements, is a very curious subject, and has always been admired by such as understood it. The first algebraical writers in Europe, such as Lucas de Burgo, Cardan, Tartalea, Stifelius, &c. employed a considerable portion of their works on an algebraical exposition of that which led them to the doctrine of surd quantities.

APPARENT conjunction of the planets, is when a right line supposed to be drawn through their centres, passes through the eye of the spectator, and not through the

the centre of the earth. And, in general, the apparent conjunction of any objects, is when they appear or are placed in the fame right line with the eye.

Apparent Diameter of a planet or other heavenly body, is not the real length of the diameter of that body, but the angle which it fubtends at the eye, or under which it appears.

Apparent Diftance, is that which we judge an object to be from us, when feen afar off; and which is almoft always very different from the true diftance.

Apparent Figure, is the figure or fhape under which an object appears when viewed at a diftance; and is often very different from the true figure. Thus a ftraight line, viewed at a diftance, may appear but as a point; a furface, as a line; and a folid, as a furface.

Apparent Motion, is either that motion which we perceive in a diftant body that moves, the eye at the fame time being either in motion or at reft; or that motion which an object at reft feems to have, while the eye itfelf only is in motion.

Apparent Place of a Planet, &c. in aftronomy, is that point in the furface of the fphere of the world where the centre of the luminary appears from the furface of the earth.

APPARITION, in aftronomy, denotes a ftar's or other luminary's becoming vifible, which before was hid. So, the heliacal rifing, is rather an apparition than a proper rifing.

APURIMA, or *Aporamac*, a very rapid river in Peru, South-America, 30 miles from the river Abanzai.—*Morse.*

AQUAFORT, a fettlement on the E. fide of the fouth-eaftern extremity of Newfoundland Ifland, lat. 47. 10. N.—*ib.*

AQUEDOCHTON, the outlet of lake Winnipifeogee, in New-Hampfhire, N. lat. 43. 40. whofe waters pafs through feveral fmaller ones in a S. W. courfe, and empty into Merrimack River, between the towns of Sanburn and Canterbury.—*ib.*

ARARAT, *Mount* or the *Stone Head*, a fhort range of mountains on the N. frontier of North-Carolina, in a N. E. direction from Ararat River, a N. W. branch of Yadkin River.—*ib.*

ARATHAPESCOW, an Indian tribe inhabiting the fhores of the lake and river of that name, in the N. W. part of North-America, between the latitudes of 57. and 59. N. North of this nation's abode, and near the Arctic Circle, is Lake Edlande, around which live the Dog Ribbed Indians.—*ib.*

ARAUCO, a fortrefs and town of Chili, in South-America; fituated in a fine valley, on a river of the fame name, N. by W. from Baldivia. The native Indians are fo brave that they drove the Spaniards out of their country, though deftitute of fire-arms. S. lat. 37. 30. W. long. 73. 20.—*ib.*

ARAZIBO, one of the principal places in Porto Rico Ifland, in the Weft-Indies. It has few inhabitants, and little trade but fmuggling.—*ib.*

ARCAS, an ifland in the Gulf of Mexico, in the Bay of Campeachy. Lat. 20. long. 92. 50.—*ib.*

ARCH, in building, is an artful difpofition and adjuftment of feveral ftones or bricks, generally in a bow-
1 Arch defined. like form, by which their weight produces a mutual preffure and abutment; fo that they not only fupport each other, and perform the office of an entire lintel, but may be extended to any width, and made to carry the moft enormous weights.

In thofe mild climates which feem to have been the firft inhabited parts of this globe, mankind ftood more in need of fhade from the fun than of fhelter from the inclemency of the weather. A very fmall addition to the fhade of the woods ferved them for a dwelling. Sticks laid acrofs from tree to tree, and covered with bruſhwood and leaves, formed the firft houfes in thofe delightful regions. As population and the arts improved, thefe huts were gradually refined into commodious dwellings. The materials were the fame, but more artfully put together. At laft agriculture led the inhabitants out of the woods into the open country. The connection between the inhabitant and the foil became now more conftant and more interefting. The wifh to preferve this connection was natural, and fixed eftablifhments followed of courfe. Durable buildings were more defirable than thofe temporary and perifhable cottages—ftone was fubftituted for timber. 2 History of architecture connected with arches.

But as thefe improved habitations were gradual refinements on the primitive hut, traces of its conftruction remained, even when the choice of more durable materials made it in fome meafure inconvenient. Thus it happened, that while a plain building, intended for accommodation only, confifted of walls, pierced with the neceffary doors and windows, an ornamented building had, fuperadded to thefe effentials, columns, with the whole apparatus of entablature, borrowed from the wooden building, of which they had been effential parts, gradually rendered more fuitable to the purpofes of accommodation and elegance.

This view of ornamental architecture will go far to account for fome of the more general differences of national ftyle which may be obferved in different parts of the world. The Greeks borrowed many of their arts from their Afiatic neighbours, who had cultivated them long before. It is highly probable that architecture travelled from Perfia into Greece. In the ruins of Shufhan, Perfepolis, or Tchilminar, are to be feen the firft models of every thing that diftinguifhes the Grecian architectures. There is no doubt, we fuppofe, among the learned, as to the great priority of thefe monuments to any thing that remains in Greece; efpecially if we take into account the tombs on the mountains, which have every appearance of greater antiquity than the remains of Perfepolis. In thofe tombs we fee the whole *ordonnance* of column and entablature, juft as they began to deviate from their firft and neceffary forms in the wooden buildings. We have the architrave, frize, and corniche; the far-projecting mutules of the Tufcan and Doric orders; the modillions no lefs diftinct; the rudiments of the Ionic capital; the Corinthian capital in perfection, pointing out the very origin of this ornament, viz. a number of long graceful leaves tied round the head of the column with a fillet (a cuftom which we know to have been common in their temples and banqueting rooms). Where the diftance between the columns is great, fo that each had to fupport a weight too great for one tree, we fee the columns cluftered or fluted, &c. In fhort, we fee every thing of the Grecian architecture but the floped roof or pediment; a thing not wanted in a country where it hardly ever rains. 3 Origin of Greek architecture.

The ancient Egyptian architecture feems to be a refinement on the hut built of clay, or unburnt bricks mix- 4 Egyptian;

ed

Arch.

ed with ſtraw—every thing is maſſive, clumſy, and timid —ſmall intercolumnations, and hardly any projections.

5 Arabian, and

The Arabian architecture ſeems a refinement on the tent. A moſque is like a little camp, conſiſting of a number of little bell tents, ſtuck cloſe together round a great one. A caravanſeray is a court ſurrounded by a row of ſuch tents, each having its own dome. The Greek church of St Sophia at Conſtantinople has imitated this in ſome degree: and the copies from it, which have been multiplied in Ruſſia as the ſacred form for a Chriſtian church, have adhered to the original model of cluſtered tents in the ſtricteſt manner. We are ſometimes diſpoſed to think that the painted glaſs (a faſhion brought from the Eaſt) was an imitation of the painted hangings of the Arabs.

6 Chineſe architecture.

The Chineſe architecture is an evident imitation of a wooden building. Sir Geo. Staunton ſays, that the ſingular form of their roofs is a *profeſſed* imitation of the cover of a ſquare tent.

In the ſtone buildings of the Greeks, the roofs were imitations of the wooden ones; hence the lintels, flying corniches, ceilings in compartments, &c.

The pediment of the Greeks ſeems to have ſuggeſted the greateſt improvement in the art of building. In erecting their ſmall houſes, they could hardly fail to obſerve occaſionally, that when two rafters were laid together from the oppoſite walls, they would, by leaning on each other, give mutual ſupport, as in fig. 1. Nor is it unlikely that ſuch a ſituation of ſtones as is repreſented in fig. 2. would not unfrequently occur by accident to maſons. This could hardly fail of exciting a little attention and reflection. It was a pretty obvious reflection, that the ſtones A and C, by overhanging, leaned againſt the intermediate ſtone B, and gave it ſome ſupport, and that B cannot get down without thruſting aſide A and C, or the piers which ſupport them. This was an approach to the theory of an arch; and if this be combined with the obſervation of fig. 1. we get the diſpoſition repreſented in fig. 3. having a perpendicular joint in the middle, and the *principle of the arch* is completed. Obſerve that this is quite different from the principle of the arrangement in fig. 2. In that figure the ſtones act as wedges, and one cannot get down without thruſting the reſt aſide; the ſame principle obtains in fig. 4. conſiſting of five arch ſtones; but in fig. 3. the ſtones B and C ſupport each other by their mutual preſſure (independent of their own weight), ariſing from the tendency of each lateral pair to fall outwards from the pier. This is the principle of the arch, and would ſupport the key-ſtone of fig. 4. although each of its joints were perpendicular, by reaſon of the great friction ariſing from the horizontal thruſt exerted by the adjoining ſtones.

Plate I.

7 Origin of the arch.

This was a moſt important diſcovery in the art of building; for now a building of any width may be roofed with ſtone.

8 Grecian.

We are diſpoſed to give the Greeks the merit of this diſcovery; for we obſerve arches in the moſt ancient buildings of Greece, ſuch as the temple of the ſun at Athens, and of Apollo at Didymos; not indeed as roofs to any apartment, nor as parts of the ornamental deſign, but concealed in the walls, covering drains or other neceſſary openings; and we have not found any *real* arches in any monuments of ancient Perſia or Egypt. Sir John Chardin ſpeaks of numerous and extenſive ſubterranean paſſages at Tchelminar, built of the moſt exquiſite maſonry, the joints ſo exact, and the ſtones ſo beautifully dreſſed, that they look like one continued piece of poliſhed marble; but he nowhere ſays that they are arched; a circumſtance which we think he would not have omitted—no arched door or window is to be ſeen. Indeed one of the tombs is ſaid to be arch-roofed, but it is all of one ſolid rock. No trace of an arch is to be ſeen in the ruins of ancient Egypt; even a wide room is covered with a ſingle block of ſtone. In the pyramids, indeed, there are two galleries, whoſe roofs conſiſt of many pieces; but their conſtruction puts it beyond doubt that the builder did not know what an arch was: for it is covered in the manner repreſented in fig. 5. where every projecting piece is more than balanced behind, ſo that the whole aukward maſs could have ſtood on two pillars. The Greeks therefore ſeem entitled to the honour of the invention. The arched dome, however, ſeems to have ariſen in Etruria, and originated in all probability from the employment of the augurs, whoſe buſineſs it was to obſerve the flight of birds. Their ſtations for this purpoſe were *templa*, ſo called *a templando*, "on the ſummits of hills." To ſhelter ſuch a perſon from the weather, and at the ſame time allow him a full proſpect of the country around him, no building was ſo proper as a dome ſet on columns; which accordingly is the figure of a temple in the moſt ancient monuments of that country. We do not recollect a building of this kind in Greece except that called the *Lanthern of Demoſthenes*, which is of very late date, whereas they abounded in Italy. In the later monuments and coins of Italy or of Rome, we commonly find the Etruſcan dome and the Grecian temple combined; and the famous pantheon was of this form, even in its moſt ancient ſtate.

Arch.

It does not appear that the arch was conſidered as a part of the *ornamental* architecture of the Greeks during the time of their independency. It is even doubtful whether it was employed in roofing their temples. In none of the *ancient* buildings where the roof is gone, can there be ſeen any rubbiſh of the vault, or mark of the ſpring of the arch. It is not unfrequent, however, after the Roman conqueſts, and may be ſeen in Athens, Delos, Palmyra, Balbek, and other places. It is very frequent in the magnificent buildings of Rome; ſuch as the Coliſeum, the baths of Diocleſian, and the triumphal arches, where its form is evidently made the object of attention. But its chief employment was in bridges and aqueducts; and it is in thoſe works that its immenſe utility is the moſt conſpicuous: For by this happy contrivance a canal or a road may be carried acroſs any ſtream, where it would be almoſt impoſſible to erect piers ſufficiently near to each other for carrying lintels. Arches have been executed 130 feet wide, and their execution demonſtrates that they may be made four times as wide.

It was uſed at firſt only in bridges and aqueducts.

As ſuch ſtupendous arches are the greateſt performances of the maſonic art, ſo they are the moſt difficult and delicate. When we reflect on the immenſe quantity of materials thus ſuſpended in the air, and compare this with the ſmall coheſion which the firmeſt cement can give to a building, we ſhall be convinced that it is not by the force of the cement that they are kept together: they ſtand faſt only in conſequence of the proper balance of all their parts. Therefore, in order to

10 Difficulty of conſtructing it.

to erect them with a well-founded confidence of their durability, this balance ſhould be well underſtood and judiciouſly employed. We doubt not but that this was underſtood in ſome degree by the engineers of antiquity. But they have left us none of their knowledge.

11 Skill and myſteries of the Dionyſiacs.

They muſt have had a great deal of mechanical knowledge before they could erect the magnificent and beautiful buildings whoſe ruins ſtill enchant the world; but they kept it among themſelves. We know that the Dionyſiacs of Ionia were a great corporation of architects and engineers, who undertook, and even monopolized, the building of temples, ſtadiums, and theatres, preciſely as the fraternity of maſons in the middle ages monopolized the building of cathedrals and conventual churches. Indeed the Dionyſiacs reſembled the myſtical fraternity now called free maſons in many important particulars. They allowed no ſtrangers to interfere in their employment; they recogniſed each other by ſigns and tokens; they profeſſed certain myſterious doctrines, under the tuition and tutelage of Bacchus, to whom they built a magnificent temple at Teos, where they celebrated his myſteries as ſolemn feſtivals; and they called all other men profane, becauſe not admitted to theſe myſteries. But their chief myſteries and moſt important ſecrets ſeem to be their mechanical and mathematical ſciences, or all that academical knowledge which forms the regular education of a civil engineer. We know that the temples of the gods and the theatres required an immenſe apparatus of machinery for the celebration of ſome of their myſteries; and that the Dionyſiacs contracted for thoſe jobs, even at far diſtant places, where they had not the privilege of building the edifice which was to contain them. This is the moſt likely way of explaining the very ſmall quantity of mechanical knowledge that is to be met with in the writings of the ancients. Even Vitruvius does not appear to have been of the fraternity, and ſpeaks of the Greek architects in terms of reſpect next to veneration. The *Collegium Murariorum*, or incorporation of maſons at Rome, does not ſeem to have ſhared the ſecrets of the Dionyſiacs.

12 The art of building arches underſtood in the middle ages.

The art of building arches has been moſt aſſiduouſly cultivated by the aſſociated builders of the middle ages of the Chriſtian church, both Saracens and Chriſtians, and they ſeem to have indulged in it with fondneſs: they multiplied and combined arches without end, placing them in every poſſible ſituation.

Having ſtudied this branch of the art of building with ſo much attention, they were able to erect the moſt magnificent buildings with materials which a Greek or Roman architect could have made little or no uſe of.

13 Better than by the Greeks and Romans.

There is infinitely more ſcientific ſkill diſplayed in a Gothic cathedral, than in all the buildings of Greece and Rome. Indeed theſe laſt exhibit very little knowledge of the mutual balance of arches, and are full of groſs blunders in this reſpect; nor could they have reſiſted the ſhock of time ſo long, had they not been almoſt ſolid maſſes of ſtone, with no more cavity than was indiſpenſably neceſſary.

Anthemius and Iſidorus, whom the Emperor Juſtinian had ſelected as the moſt eminent architects of Greece for building the celebrated church of St Sophia at Conſtantinople, ſeem to have known very little of this matter. Anthemius had boaſted to Juſtinian, that he would outdo the magnificence of the Roman pantheon, for he would hang a greater dome than it aloft in the air. Accordingly he attempted to raiſe it on the heads of four piers, diſtant from each other about 115 feet, and about the ſame height. He had probably ſeen the magnificent vaultings of the temple of Mars the Avenger, and the temple of Peace at Rome, the thruſts of which are withſtood by two maſſes of ſolid wall, which join the ſide walls of the temple at right angles, and extend ſidewiſe to a great diſtance. It was evident that the walls of the temple could not yield to the preſſure of the vaulting without puſhing theſe immenſe buttreſſes along their foundations. He therefore placed four buttreſſes to aid his piers. They are almoſt ſolid maſſes of ſtone, extending at leaſt 90 feet from the piers to the north and to the ſouth, forming as it were the ſide walls of the croſs. They effectually ſecured them from the thruſts of the two great arches of the nave which ſupport the dome; but there was no ſuch proviſion againſt the puſh of the great north and ſouth arches. Anthemius truſted for this to the half dome, which covered the ſemicircular eaſt end of the church, and occupied the whole eaſtern arch of the great dome. But when the dome was finiſhed, and had ſtood a few months, it puſhed the two eaſtern piers with their buttreſſes from the perpendicular, making them lean to the eaſtward, and the dome and half dome fell in. Iſidorus, who ſucceeded to the charge on the death of Anthemius, ſtrengthened the piers on the eaſt ſide, by filling up ſome hollows, and again raiſed the dome. But things gave way before it was cloſed; and while they were building in one part it was falling in in another. The pillars and walls of the eaſtern ſemicircular end were much ſhattered by this time. Iſidorus ſeeing that they could give no reſiſtance to the puſh which was ſo evidently directed that way, erected ſome clumſy buttreſſes on the eaſt wall of the ſquare which ſurrounded the whole Greek croſs, and was roofed in with it, forming a ſort of cloiſter round the whole. Theſe buttreſſes, ſpanning over this cloiſter, leaned againſt the piers of the dome, and thus oppoſed the thruſts of the great north and ſouth arches. The dome was now turned for the third time, and many contrivances were adopted for making it extremely light. It was made offenſively flat: and, except the ribs, it was roofed with pumice ſtone; but notwithſtanding theſe precautions, the arches ſettled ſo as to alarm the architects, and they made all ſure by filling up the whole from top to bottom with arcades in three ſtories. The loweſt arcade was very lofty, ſupported by four noble marble columns, and thus preſerved, in ſome meaſure, the church in the form of a Greek croſs. The ſtory above formed a gallery for the women, and had ſix columns in front, ſo that they did not bear fair on thoſe below. The third ſtory was a dead wall filling up the arch, and pierced with three rows of ſmall ill-ſhaped windows. In this unworkmanlike ſhape it has ſtood till now, and is the oldeſt church in the world; but it is an ugly miſhapen maſs, more reſembling an overgrown potter's kiln, ſurrounded with furnaces pieced and patched, than a magnificent temple. We have been thus particular in our account of it, becauſe this hiſtory of the building ſhows that the ancient architects had acquired no diſtinct notions of the action of arches. Almoſt any maſon of our time would know, that as the ſouth arch would puſh the pier to the eaſtward, while the eaſt arch puſhed it to the ſouthward, the

14 Defects of the church of St Sophia at Conſtantinople.

Arch.

the buttress which was to withstand these thrusts must not be placed on the south side of the pier, but on the south-east side, or that there must be an eastern as well as a southern buttress. No such blunders are to be seen in a Gothic cathedral. Some of them appear, to a careless spectator, to be very massive and clumsy; but when judiciously examined, they will be found very bold and light, being pierced in every direction by arcades, and the walls are divided into cells like a honeycomb, so that they are very stiff, while they are very light.

15 Such as are never found in a Gothic church.

About the middle, or rather towards the end, of last century, when the Newtonian mathematics opened the road to true mechanical science, the construction of arches engrossed the attention of the first mathematicians. The first hint of a principle that we have met with is Dr Hooke's assertion, that the figure into which a chain or rope, perfectly flexible, will arrange itself when suspended from two hooks, is, when inverted, the proper form for an arch composed of stones of uniform weight. This he affirmed on the same principle which is made use of in the Encyclopædia in the article Roof, § 25. viz. that the figure which a flexible festoon of heavy bodies assumes, when suspended from two points, is, when inverted, the proper form for an arch of the same bodies, touching each other in the same points; because the forces with which they mutually press on each other in this last case, are equal and opposite to the forces with which they pull at each other in the case of suspension.

16 Dr Hooke's principle of arches

This principle is strictly just, and may be extended to every case which can be proposed. We recollect seeing it proposed, in very general terms, in the St. James's Chronicle in 1759, when plans were forming for Blackfriar's Bridge in London; and since it is perhaps equal, in practical utility, to the most elaborate investigations of the mathematicians, our readers will not be displeased with a more particular account of it in this place.

17 Explained,

Let ABC (fig. 6.) be a parcel of magnets of any size and shape, and let us suppose that they adhere with great force by any points of contact. They will compose such a flexible festoon as we have been speaking of, if suspended from the points A and C. If this figure be inverted, preserving the same points of contact, they will remain in equilibrio. It will indeed be that kind of equilibrium which will admit of no disturbance, and which may be called a *tottering equilibrium*. If the form be altered in the smallest degree, by varying the points of contact (which indeed are points in the *figure of equilibration*), the magnets will no more recover their former position than a needle, which we had made to stand on its point, will regain its perpendicular position after it has been disturbed.

But if we suppose planes *de*, *fg*, *hi*, &c. drawn, that the points of mutual contact *a*, *b*, *c*, each bisecting the angle formed by the lines that unite the adjoining contacts (*fg*, for example, bisecting the angle formed by *ab*, *bc*), and if we suppose that the pieces are changed for others of the same weights, but having flat sides, which meet in the planes *de*, *fg*, *hi*, &c. it is evident that we shall have an arch of equilibration, and that the arch will have some stability, or will bear a little change of form without tumbling down: for it is plain that the equilibrium of the original festoon obtained only in the points *a*, *b*, *c*, of contact, where the pressures were perpendicular to the touching surfaces; therefore if the curve *a*, *b*, *c*, still passes through the touching surfaces perpendicularly, the conditions that are required for equilibrium still obtain. The case is quite similar to that of the stability of a body resting on a horizontal plane. If the perpendicular through the centre of gravity falls within the base of the body, it will not only stand, but will require some force to push it over. In the original festoon, if a small weight be added in any part, it will change the form of the curve of equilibration a little, by changing the points of mutual contact. This new curve will gradually separate from the former curve as it recedes from A or C. In like manner, when the festoon is set up as an arch, if a small weight be laid on any part of it, it will bring the whole to the ground, because the shifting of the points of contact will be just the contrary to what it should be to suit the new curve of equilibration. But if the same weight be laid on the same part of the arch now constructed with flat joints, it will be sustained, if the new curve of equilibration still passes through the touching surfaces.

These conclusions, which are very obviously deducible from the principle of the festoon, shew us, without any further discussion, that the longer the joints are, the greater will be the stability of the arch, or that it will require a greater force to break it down. Therefore it is of the greatest importance to have the arch stones as long as economy will permit; and this was the great use of the ribs and other apparent ornaments in the Gothic architecture. The great projections of those ribs augmented their stiffness, and enabled them to support the unadorned copartments of the roof, composed of very small stones, seldom above six inches thick. Many old bridges are still remaining, which are strengthened in the same way by ribs.

Having thus explained, in a very familiar manner, the stability of an arch, we proceed to give the same popular account of the general application of the principle.

18 And applied.

Suppose it to be required to ascertain the form of an arch which shall have the span AB (fig. 7.), and the height F 8, and which shall have a road-way of the dimensions CDE above it. Let the figure ACDEB be inverted, so as to form a figure A *c d e* B. Let a chain of uniform thickness be suspended from the points A and B, and let it be of such a length that its lower point will hang at, or rather a little below, *f*, corresponding to F. Divide AB into a number of equal parts, in the points 1, 2, 3, &c. and draw vertical lines, cutting the chain in the corresponding points 1, 2, 3, &c. Now take pieces of another chain, and hang them on at the points 1, 2, 3, &c. of the chain A *f* B. This will alter the form of the curve. Cut or trim these pieces of chain, till their lower ends all coincide with the inverted road-way *c d e*. The greater lengths that are hung on in the vicinity of A and B will pull down these points of the chain, and cause the middle point *f* (which is less loaded) to rise a little, and will bring it near to its proper height.

It is plain that this process will produce an arch of perfect equilibration; but some farther considerations are necessary for making it exactly suit our purpose. It is an arch of equilibration for a bridge, that is so loaded that the weight of the arch stones is to the weight of the matter with which the haunches and crown are loaded, as the weight of the chain A *f* B is to

Arch.

to the sum of the weights of all the little bits of chain very nearly. But this proportion is not known beforehand; we must therefore proceed in the following manner: Adapt to the curve produced in this way a thickness of the arch stones as great as are thought sufficient to ensure stability; then compute the weight of the arch stones, and the weight of the gravel or rubbish with which the haunches are to be filled up to the road-way. If the proportion of these two weights be the same with the proportion of the weights of chain, we may rest satisfied with the curve now found; but if different, we can easily calculate how much must be added equally to, or taken from, each appended bit of chain, in order to make the two proportions equal. Having altered the appended pieces accordingly, we shall get a new curve, which may perhaps require a very small trimming of the bits of chain to make them fit the road-way. This curve will be infinitely near to the curve wanted.

We have practised this method for an arch of 60 feet span and 21 feet height, the arch stones of which were only two feet nine inches long. It was to be loaded with gravel and shivers. We made a previous computation, on the supposition that the arch was to be nearly elliptical. The distance between the points 1, 2, 3, &c. were adjusted, so as to determine the proportion of the weights of chain agreeable to the supposition. The curve differed considerably from an ellipse, making a considerable angle with the verticals at the spring of the arch. The real proportion of the weights of chain, when all was trimmed so as to suit the road-way, was considerably different from what was expected. It was adjusted. The adjustment made very little change in the curve. It would not have changed it two inches in any part of the real arch. When the process was completed, we constructed the curve mathematically. It did not differ sensibly from this mechanical construction. This was very agreeable information; for it showed us that the first curve, formed by about two hours labour, on a supposition considerably different from the truth, would have been sufficiently exact for the purpose, being in no place three inches from the accurate curve, and therefore far within the joints of the intended arch stones. Therefore this process, which any intelligent mason, though ignorant of mathematical science, may go through with little trouble, will give a very proper form for an arch subject to any conditions.

19
The chief defect of the curve found according to this principle.

The chief defect of the curve found in this way is a want of elegance, because it does not spring at right angles to the horizontal line; but this is the case with all curves of equilibration, as we shall see by and by. It is not material: for, in the very neighbourhood of the piers, we may give it any form we please, because the masonry is solid in that place; nay, we apprehend that a deviation from the curve of equilibration is proper. The construction of that curve supposes that the pressure on every part of the arch is vertical; but gravel, earth, and rubbish, exert somewhat of a hydrostatical pressure laterally in the act of settling, and retain it afterwards. This will require some more curvature at the haunches of an arch to balance it; but what this lateral pressure may be, cannot be deduced with confidence from any experiments that we have seen. We are inclined to think that if, instead of dividing the horizontal line AB in the points 1, 2, 3, &c. we divide the chain itself into equal parts, the curve will approach nearer to the proper form.

20
Theory founded on this principle.

After this familiar statement of the general principle, it is now time to consider the theory founded on it more in detail. This theory aims at such an adjustment of the position of the arch stones to the load on every part of the arch, that all shall remain in equilibrio, although the joints be perfectly polished, and without any cement. The whole may be reduced to two problems. The first is to determine the vertical pressure or load on every point of a line of a given form, which will put that line in equilibrio. The second is to determine the form of a curve which shall be in equilibrio when loaded in its different points, according to any given law.

The whole theory is deducible from § 27. of the article Roof. The fundamental proposition in that section states the proportions between the various pressures or thrusts which are exerted at the angles of an assemblage of beams or other pieces of solid heavy matter, freely moveable about those angles, as so many joints, but retaining their position by the equilibrium of those pressures. It is there demonstrated, "that the thrust at any angle, if estimated in a horizontal direction, is the same throughout, and may be represented by any horizontal line BT, fig. 8. (Roofs, fig. 10. Pl. CCCCXL); and that if a vertical line QTS be drawn through T, the thrust exerted at any angle D by the piece CD, in its own direction, will then be represented by BR, drawn parallel to CD; and in like manner, that the thrust in the direction ED is represented by BS, &c.; and, lastly, that the vertical thrusts or loads, at each angle B, C, D, by which all these other pressures are excited, are represented by the portions QC, CR, RS, of the vertical intercepted by those lines; that is, all these pressures are to the uniform horizontal thrust as the lines which represent them are to BT. The horizontal thrust, therefore, is a very proper unit, with which we may compare all the others. Its magnitude is easily deduced from the same proposition; for QS is the sum of all the vertical pressures of the angles, and therefore represents the weight of the whole assemblage. Therefore as QS is to BT, so is the weight of the whole to the horizontal thrust.

21
Accommodated to the construction of an arch vault,

To accommodate this theory to the construction of a curvelineal arch vault, let us first suppose the vault to be polygonal, composed of the cords of the elementary arches. Let AVE (fig. 9.) be a curvelineal arch, of which V is the vertex, and VX the vertical axis, which we shall consider as the axis or abscissa of the curve, while any horizontal line, such as HK, is an ordinate to the curve. About any point C of the curve as a centre describe a circle BLD, cutting the curve in B and D. Draw the equal cords CB, CD. Draw also the horizontal line CF, cutting the circle in F. Describe a circle BCDQ passing through B, C, D. Its centre O will lie in a line CCQ, which bisects the angle BCD, and C *d*, which touches this circle in C, will bisect the angle *b* C *d*, formed by the equal cords BC, CD. Draw CLP perpendicular to *cb*, and DP perpendicular to CD, meeting CL in P. Through L draw the tangent GLM, meeting CD in G, and the vertical line CM in M. Draw the tangent F *a*, cutting the cords BC, CD, in *b* and *d*, and the tangent to the circle BCDQ in *c*. Lastly, draw *d* N parallel to *b c*.

From

Arch. From what is demonstrated in § 27. of the article Roof, it appears, that if BC, CD be two pieces of an equilibrated heavy polygon, and if CF represent the horizontal thrust in every angle of the polygon, C d and C b will severally represent the thrusts exerted by the pieces DC, BC, and that $b\,d$, or CN, will represent the weight lying on the angle BCD, by which those thrusts are balanced.

As the reader may not have the article Roof at hand, this equilibrium may be recalled to his remembrance in the following manner: Produce d C to o, so that C o may be equal to C d. Draw $b\,n$ to the vertical parallel to d B, and join $n\,o$. It is evident that $b\,n\,o$ C is a parallelogram, and that n C ($= b\,d$)=CN. Now the thrust or support of the piece BC is exerted in the direction C b, while that of DC is exerted in the direction C o. These two thrusts are equivalent to the thrust in the diagonal C n; and it is with this compound thrust that the load or vertical pressure CN is in *immediate* equilibrium.

22 And demonstrated. Because b CL, NCF, are right angles, and FCL is common to both, the angles b CF and MCL are equal. Therefore the right angled triangles b CF and MCL are similar. And since CF is equal to CL, $c\,b$ is equal to CM. It is evident that the triangles GCM and d CN are similar. Therefore CG : C d = CM : CN, = C b : CN. Therefore we have $\mathrm{CN} = \frac{\mathrm{C}b \times \mathrm{C}d}{\mathrm{CG}}$. But because CDP and CLG are right angles, and therefore equal, and the angle GCP is common to the two triangles GCL, PCD, and CD is equal to CL, we have CG equal to CP. Therefore $\mathrm{CN} = \frac{\mathrm{C}b \times \mathrm{C}d}{\mathrm{CP}}$. Also, since CDP is a right angle, DP meets the diameter in Q, the opposite point of the circumference, and the angle DQC is equal to DC d, or DC b (because b C d is bisected by the tangent), that is, to PCQ (because the right angles b CP, c DO are equal, and c DP is common). Therefore PQ is equal to PC; and if PO be drawn perpendicular to CQ, it will bisect it, and O is the centre of the circle BCDQB.

Now let the points B and D continually approach to C (by diminishing the radius of the small circle), and ultimately coincide with it. It is evident that the circle BCDQ is ultimately the equicurve circle, and that PC ultimately coincides with OC, the radius of curvature. Also C $b \times$ C d becomes ultimately C c^2. Therefore CN, the vertical load on any point of a curve of equilibration, is $= \frac{\mathrm{C}c^2}{\text{Rad. Curv.}}$

It is farther evident, that CF is to C c as radius to the secant of the elevation of the tangent above the horizon. Therefore we have the load on any point of the curve always proportional to $\frac{\text{Sec.}^2 \text{ Elev.}}{\text{Rad. Curv.}}$

This load on every elementary arch of the wall is commonly a quantity of solid matter incumbent on that element of the curve, and pressing it vertically; and it may be conceived as made up of a number of heavy lines standing vertically on it. Thus, if the element E e of the curve were lying horizontally, a little parallelogram RE $e\,r$, standing perpendicularly on it, would represent its load. But as this element E e has a sloping position, it is plain that, in order to have the same quantity of heavy matter pressing it vertically, the height of the parallelogram must be increased till it meets in $e\,\rho$, the line R e drawn parallel to the tangent EG. It is evident that the angle RE ρ is equal to the angle AEG. Therefore we have ER : E ρ = Rad. : Sec. Elev. Arch.

If therefore the arch is kept in equilibrio by the vertical pressure of a wall, we must have the height of the wall above any point proportional to $\frac{\text{Sec.}^3 \text{ Elev.}}{\text{Rad. of Curv.}}$ 23

Cor. I. If OS be drawn perpendicular to the vertical CS, CS will be half the vertical cord of the equicurve circle. The angle OCS is equal to c CF, that is, to the angle of elevation. Therefore 1 : Sec. Elev. = CS : CO, and the secant of elevation may be expressed by $\frac{\mathrm{CO}}{\mathrm{CS}}$, and its cube by $\frac{\mathrm{CO}^3}{\mathrm{CS}^3}$. Therefore the height of wall is proportional to $\frac{\mathrm{CO}^3}{\mathrm{CS}^3 \times \mathrm{CO}}$, or to $\frac{\mathrm{CO}^2}{\mathrm{CS}^3}$, or $\frac{\mathrm{CO}^2}{\mathrm{CS}^2 \times \mathrm{CS}}$, or to $\frac{\text{Sec.}^2 \text{ of Elev.}}{\text{Vert. Cord of Curv.}}$ Corollaries.

Cor. II. If we make the arch VC = z, the abscissa VH=x, the ordinate HC=y, the radius osculi CO=r, and the $\frac{1}{2}$ vertical cord CS = s, the height of wall pressing on any point is proportional to $\frac{\dot{z}^3}{\dot{y}^3 r}$; or to $\frac{\dot{z}^2}{\dot{y}^2 s}$, or $\frac{\dot{x}^2+\dot{y}^2}{\dot{y}^2 s}$. Therefore, when the equation of the curve is given, and the height of wall on any one point of it is also given, we can determine it for any other point: for the equation of the curve will always give us the relation of $\dot{z}$, $\dot{x}$, and $\dot{y}$, and the value of r or s. This may be illustrated by an example or two. For this purpose it will generally be most convenient to assume the height above the vertex V for the unit of computation. The thickness of the arch at the crown is commonly determined by other circumstances. At the vertex the tangent to the arch is horizontal, and therefore the cube of the secant is unity or 1. Call the height of wall, at the crown, H, and let the radius of curvature in that point be R, and its half cord R (it being then coincident with the radius), and the height on any other point h. We have $\frac{1}{\mathrm{R}} : \frac{\dot{z}^3}{\dot{y}^3 r} = \mathrm{H} : h$, and $h = \mathrm{H} \times \frac{\dot{z}^3}{\dot{y}^3} \times \frac{\mathrm{R}}{r}$. The other formula gives $h = \mathrm{H} \times \frac{\dot{z}^2}{\dot{y}^2} \times \frac{\mathrm{R}}{s}$.

24 Illustrated by examples. *Examp.* 1. Suppose the arch to be a segment of a circle, as in fig. 10. where AE is the diameter, and O the centre. In this arch the curvature is the same throughout, or $\frac{\mathrm{R}}{r} = 1$. Therefore $h = \mathrm{H} \times \frac{\dot{z}^3}{\dot{y}^3}$, or $= \mathrm{H} \times$ Cube Sec. Elev.

This gives a very simple calculus. To the logarithm of H add thrice the logarithm of the secant of elevation. The sum is the logarithm of h.

It gives also a very simple construction. Draw the vertical CS, cutting the horizontal diameter in S. Draw ST, cutting the radius OC perpendicularly in T. Draw the horizontal line T z, cutting the vertical in z. Join $z\,o$. Make C u = V v, and draw $u\,x$ parallel to $z\,o$. C c must be made = C x. The demonstration is evident.

It is very easy to see that if CV is an arch of 60°, and V v is $\frac{1}{14}$th of VC, the points v and c will be on a level;

Arch.

a level; for the fecant of CV is twice CO, and therefore C c is 8 times V v, which is $\frac{1}{7}$th of VH.

The dotted line $v\,g\,c\,f$ is drawn according to this calculus or conftruction. It falls confiderably below the horizontal line in the neighbourhood of c; and then, paffing very obliquely through c, it rifes rapidly to an unmeafurable height, becaufe the vertical line through A is its affymptote. This muft evidently be the cafe with every curve which fprings at right angles with a horizontal line.

It is plain that if v V be greater, all the other ordinates of the curve $v\,g\,c\,f$, refting on the circumference AVE, will be greater in the fame proportion, and the curve will cut the horizontal line drawn through v in fome point nearer to v than c is. Hence it appears that a circular arch cannot be put in equilibrio by building on it up to a horizontal line, whatever be its fpan, or whatever be the thicknefs at the crown. We have feen that when this thicknefs is only $\frac{1}{14}$th of the radius, an arch of 120 degrees will be too much loaded at the flanks. This thicknefs is much too fmall for a bridge, being only $\frac{1}{25}$th of the fpan CM, whereas it fhould have been almoft double of this, to bear the inequalities of weight that may occafionally be on it. When the crown is made ftill thinner, the outline is ftill more depreffed before it rifes again. There is therefore a certain fpan, with a correfponding thicknefs at the crown, which will deviate leaft of all from a horizontal line. This is an arch of about 54 degrees, the thicknefs at the crown being about one-fourth of the fpan, which is extravagantly great. It appears in general therefore, that the circle is not a curve fuited to the purpofes of a bridge or an arcade, which requires an outline nearly horizontal.

Examp. 2. Let the curve be a parabola AVE (fig. 11.), of which V is the vertex, and DG the directrix. Draw the diameters DCF, GVN, the tangent CK, VP, and the ordinates VF and CN. It is well known that GV is to DC as VP^2 to CK^2, or as CN^2 to CK^2. Alfo 2 GV is the radius of the ofculating circle at V, and 2 DC is one-half of the vertical cord of the ofculating circle at C. Therefore $CN^2 : CK^2$ (or $\dot{y}^2 : \dot{z}^2$) $= R : s$, and $s = \frac{\dot{z}^2}{\dot{y}^2}R$. But C c, or $h = H \times \frac{\dot{z}^2 R}{\dot{y}^2 S}$. Therefore

$$h = H \times \frac{\dot{z}^2 \quad R}{\dot{y}^2 \frac{\dot{z}^2}{\dot{y}^2}R}, \; = H \times \frac{\dot{z}^2 R}{\dot{z}^2 R}, \; = H. \quad \text{Therefore}$$

$C\,c = v\,V$.

It follows from this inveftigation, that the back or extrados of a parabolic arch of equilibration muft be parallel to the arch or foffit itfelf; or that the thicknefs of the arch, eftimated in a vertical direction, muft be equal throughout; or that the extrados is the fame parabola with the foffit or intrados.

We have felected thefe two examples merely for the fimplicity and perfpicuity of the folutions, which have been effected by means of elementary geometry only, inftead of employing the analytical value of the radius of the ofculatory circle viz. $\frac{\dot{z}^3}{\dot{y}\,\ddot{x} - \dot{x}\,\ddot{y}}$, which would have involved us at leaft in the elements of fecond fluxions. We have alfo preferred fimplicity to elegance in the inveftigation, becaufe we wifh to inftruct the practical engineer, who may not be a proficient in the higher mathematics.

Arch.

25 The converfe of the problem, namely, to find the form of the arch when the figure of the back of it is given, is the moft ufual queftion of the two, at leaft in cafes which are moft important and moft difficult. Of thefe perhaps bridges are the chief. Here the neceffity of a road-way, of eafy and regular afcent, confines us to an outline nearly horizontal, to which the curve of the arch muft be adapted. This is the moft difficult problem of the two; and we doubt whether it can be folved without employing infinite approximating feriefes inftead of accurate values.

To find the form of an arch when the figure of its back is given.

Let $a\,v\,e$ (fig. 12.) be the intended outline or extrados of the arch AVE, and let v Q be the common axis of both curves. From c and C, the correfponding points, draw the ordinates $c\,h$, CH. Let the thicknefs v V at the top be a, the abfciffa $v\,h$ be $= u$, and VH $= x$, and let the equal ordinates $c\,h$, CH be y, and the arch VC be z.

Then, by the general theorem, $c\,C = \frac{\dot{z}^3}{r\,\dot{y}^3}$, r being the radius of curvature. This, by the common rules, is $= \frac{\dot{z}^3}{\dot{y}\,\ddot{x} - \dot{x}\,\ddot{y}}$. This gives us $c\,C \doteq \frac{\dot{y}\,\ddot{x} - \dot{x}\,\ddot{y}}{\dot{y}^3}$, or $= \frac{\dot{y}\,\ddot{x} - \dot{x}\,\ddot{y}}{\dot{y}^3} \times C$; where C is a conftant quantity, found by taking the real value of $c\,C$ in V, the vertex of the curve. But it is evident that it is alfo $= a + x - u$. Therefore $a + x - u = \frac{\dot{y}\,\ddot{x} - \dot{x}\,\ddot{y}}{\dot{y}^3} \times C, = \frac{C}{\dot{y}} \times$ fluxion of $\frac{\dot{x}}{\dot{y}}$.

If we now fubftitute the true value of u (which is given, becaufe the extrados is fuppofed to be of a known form), expreffed in terms of y, the refulting equation will contain nothing but x and y, with their firft and fecond fluxions, and known quantities. From this equation the relation of x and y muft be found by fuch methods as feem beft adapted to the equation of the extrados.

Fortunately the procefs is more fimple and eafy in the moft common and ufeful cafe than we fhould expect from this general rule. We mean the cafe where the extrados is a ftraight line, efpecially when this is horizontal. In this cafe u is equal to o.

Example. To find the form of the balanced arch AVE (fig. 13.), having the horizontal line $c\,v$ for its extrados. Plate II.

Keeping the fame notation, we have $u = o$, and therefore $a + x = \frac{C}{\dot{y}} \times$ fluxion of $\frac{\dot{x}}{\dot{y}}$.

Affume $\dot{y} = \frac{\dot{x}}{v}$; then $\frac{\dot{x}}{\dot{y}} = v$, and $\frac{C}{\dot{y}} \times$ fluxion of $\frac{\dot{x}}{\dot{y}}$, $= \frac{C v \dot{v}}{\dot{x}}$, that is $a + x = \frac{C v \dot{v}}{\dot{x}}$. Therefore $a\dot{x} + x\dot{x} = C v \dot{v}$; and by taking the fluents, we have $2ax + x^2 = C v^2$; and $\dot{v} = \sqrt{\frac{2ax + x^3}{C}}$. Confequently, $\dot{y} =$

$\dot{y} = \frac{\sqrt{C}\,\dot{x}}{\sqrt{2ax \times x^2}}\left(\text{being} = \frac{\dot{x}}{v}\right)$. Taking the fluent of this, we have $y = \sqrt{C} \times L\,(2ax + 2x^2 + 2\sqrt{2ax + x^2})$. But at the vertex, where $x = 0$, we have $y = \sqrt{C} \times L\,(2a)$. The corrected fluent is therefore $y = \sqrt{C} \times L\,\frac{a + x + \sqrt{2ax + x^2}}{a}$.

It only remains to find the conſtant quantity C. This we readily obtain by ſelecting ſome point of the extrados where the values of x and y are given by particular circumſtances of the caſe. Thus, when the ſpan $2s$ and height h of the arch are given, we have $s = \sqrt{C} \times L\left(\frac{a + h + \sqrt{2ah + h^2}}{a}\right)$, and conſequently $\sqrt{C} = \frac{s}{L\left(\frac{a + h + \sqrt{2ah + h^2}}{a}\right)}$. Therefore

the general value of $y = s \times \frac{L\left(\frac{a + x + \sqrt{2ax + x^2}}{a}\right)}{L\left(\frac{a + h + \sqrt{2ah + h^2}}{a}\right)}$;

$$= \frac{s}{L\frac{a + h + \sqrt{2ah + h^2}}{a}} \times L\,\frac{a + x + \sqrt{2ax + x^2}}{a}.$$

As an example of the uſe of this formula, we ſubjoin a table calculated by Dr Hutton of Woolwich for an arch, the ſpan of which is 100 feet and the height 40, which are nearly the dimenſions of the middle arch of Blackfriars Bridge in London.

y	x	y	x	y	x

26 Defects of the Catenarian curve.

The figure for this propoſition is exactly drawn according to theſe dimenſions, that the reader may judge of it as an object of ſight. It is by no means deficient in gracefulneſs, and is abundantly roomy for the paſſage of craft; ſo that no objection can be offered againſt its being adapted on account of its mechanical excellency.

The reader will perhaps be ſurpriſed that we have made no mention of the celebrated Catenarean curve, which is commonly ſaid to be the beſt form for an arch; but a little reflection will convince him, that although it is the only form for an arch conſiſting of ſtones of equal weight, and touching each other only in ſingle points, it cannot ſuit an arch which muſt be filled up in the haunches, in order to form a road-way. He will be more ſurpriſed to hear, after this, that there is a certain thickneſs at the crown, which will put the Catenarea in equilibrio, even with a horizontal road-way; but this thickneſs is ſo great as to make it unfit for a bridge, being ſuch that the preſſure at the vertex is equal to the horizontal thruſt. This would have been about 37 feet in the middle arch of Blackfriars Bridge. The only ſituation therefore in which the Catenarean form would be proper, is an arcade carrying a height of dead wall; but in this ſituation it would be very ungraceful. Without troubling the reader with the inveſtigation, it is ſufficient to inform him that in a Catenarean arch of equilibration the abſciſſa VH is to the abſciſſa $v\,h$ in the conſtant ratio of the horizontal thruſt to its exceſs above the preſſure on the vertex.

27 Inutility of the common theory of equilibration.

This much will ſerve, we hope, to give the reader a clear notion of this celebrated theory of the equilibrium of arches, one of the moſt delicate and important applications of mathematical ſcience. Volumes have been written on the ſubject, and it ſtill occupies the attention of mechanicians. But we beg leave to ſay, with great deference to the eminent perſons who have proſecuted this theory, that their ſpeculations have been of little ſervice, and are little attended to by the practitioner. Nay, we may add, that Sir Chriſtopher Wren, perhaps the moſt accompliſhed architect that Europe has ſeen, ſeems to have thought it of little value: for, among the fragments which have been preſerved of his ſtudies, there are to be ſeen ſome imperfect diſſertations on this very ſubject, in which he takes no notice of this theory, and conſiders the balance of arches in quite another way. Theſe are collected by the author of the account of Sir Chriſtopher Wren's family. This man's great ſagacity, and his great experience in building, and, ſtill more his experience in the repairs of old and crazy fabrics, had ſhown him many things very inconſiſtent with this theory, which appears ſo ſpecious and ſafe. The general facts which occur in the failure of old arches are highly inſtructive, and deſerve the moſt careful attention of the engineer; for it is in this ſtate that their defects, and the proceſs of nature in their deſtruction, are moſt diſtinctly ſeen. We venture to affirm, that a very great majority of theſe facts are irreconcileable to the theory. The way in which circular arches commonly fail, is by the ſinking of the crown and the riſing of the flanks. It will be found by calculation, that in moſt of the caſes it ought to have been juſt the contrary. But the cleareſt proof is, that arches very rarely fail where their load differs moſt remarkably from that which this theory allows. Semicircular arches have ſtood the power of ages, as may be ſeen in the bridges of ancient Rome, and in the numerous arcades which the ancient inhabitants have erected. Now all arches which ſpring perpendicularly from the horizontal line, require, by this theory, a load of infinite height; and, even to a conſiderable diſtance from the ſpringing of the arch, the load neceſſary for the theoretical equilibrium is many times greater than what is ever laid on thoſe parts; yet a failure in the immediate neighbourhood of the ſpring of an arch is a moſt rare phenomenon, if it ever was obſerved. Here is a moſt remarkable deviation from the theory; for, as is already obſerved, the load is frequently not the fourth part of what the theory requires.

Many other facts might be adduced which ſhow great deviations

Arch.

deviations from the legitimate refults from the theory. We hope to be excufed, therefore, by the mathematicians for doubting of the juftnefs of this theory. We do not think it erroneous, but defective, leaving out circumftances which we apprehend to be of great importance; and we imagine that the defects of the theory have arifen from the very anxiety of the mechanicians to make it perfect. The arch ftones are fuppofed to be perfectly fmooth or polifhed, and not to be connected by any cement, and therefore to fuftain each other merely by the equilibrium of their vertical preffure. The theory enfures this equilibrium, and this only, leaving unnoticed any other caufes of mutual action.

28
Its defects.

The authors who have written on the fubject fay exprefsly, that an arch which thus fuftains itfelf muft be ftronger than another which would not; becaufe when, in imagination, we fuppofe both to acquire connection by cement, the firft preferves the influence of this connection unimpaired; whereas in the other, part of the cohefion is wafted in counteracting the tendency of fome parts to break off from the reft by their want of equilibrium. This is a very fpecious argument, and would be juft, if the forces which are mutually exerted between the parts of the arch in its fettled ftate were merely vertical preffures, or, where different, were inconfiderable in comparifon with thofe which are really attended to in the conftruction.

But this is by no means the cafe. The forms which the ufes for which arches are erected oblige us to adopt, and the loads laid on the different points of the arch, frequently deviate confiderably from what are neceffary for the equilibrium of vertical preffures. The varying load on a bridge, when a great waggon paffes along it, fometimes bears a very fenfible proportion to the weight of that point of the arch on which it refts. It is even very doubtful whether the preffures which are occafioned by the weight of the ftuff employed for filling up the flanks really act in a vertical direction, and in the proportion which is fuppofed. We are pretty certain that this is not the cafe with fand, gravel, fat mould, and many fubftances in very general ufe for this purpofe. When this is the cafe, the preffures fuftained by the different parts of the arch are often very inconfiftent with the theory—a part of the arch is overloaded, and tends to fall in, but is prevented by the cement. This part of the arch therefore acts on the remoter parts by the intervention of the parts between, employing thofe intermediate parts as a kind of levers to break the arch in a remote part, juft as a lintel would be broken. We apprehend that a mathematician would be puzzled how to explain the ftability of an arch cut out of a folid and uniform mafs of rock. His theory confiders the mutual thrufts of the arch ftones as in the direction of the tangents to the arch. Why fo? becaufe he fuppofes that all his polifhed joints are perpendicular to thofe tangents. But in the prefent cafe he has no exifting joints; and there feems to be nothing to direct his imagination in the affumption of joints, which, however, are abfolutely neceffary for employing his theory, becaufe, without a fuppofition of this kind, there feems no conceiving any mutual abutment of the arch ftones. Afk a common, but intelligent, mafon what notion he forms of fuch an arch? We apprehend that he will confider it as no arch, but as a lintel, which may be broken like a wooden lintel, and which refifts entirely by its cohefion. He will not readily conceive that, by cutting the under fide of a ftone lintel into an arched form, and thus taking away more than half of its fubftance, he has changed its nature of a lintel, or given it any additional ftrength. Nor would there be any change made in the way in which fuch a mafs of ftone would refift being broken down, if nothing were done but forming the under fide into an arch. If the lintel be fo laid on the piers that it can be broken without its parts pufhing the piers afide (which will be the cafe if it lies on the piers with horizontal joints), it will break like any other lintel; but if the joints are directed downwards, and converging to a point within the arch, the broken ftone (fuppofe it broken at the crown by an overload in that part) cannot be preffed down without forcing the piers outwards. Now, in this mode of acting, the mind cannot trace any thing of the ftatical equilibrium that we have proceeded on in the foregoing theory. The two parts of the broken lintel feem to pufh the piers afide in the fame manner that two rafters pufh outwards the walls of a houfe, when their feet are not held together by a tye-beam. If the piers cannot be pufhed afide (as when the arch abuts on two folid rocks), nothing can prefs down the crown which does not crufh the ftone.

This conclufion will be ftrictly true if the arch is of fuch a form that a ftraight line drawn from the crown to the pier lies wholly within the folid mafonry. Thus if the vault confift of two ftraight ftones, as in fig. 1. or if it confift of feveral ftones, as in fig. 14. difpofed in two ftraight lines, no weight laid on the crown can deftroy it in any other way but by crufhing it to powder.

29
When it is to be called into the aid of the builder.

But when ftraight lines cannot be drawn from the overloaded part to the firm abutments through the folid mafonry, and when the cohefion of the parts is not able to withftand the tranfverfe ftrains, we muft call the principles of equilibrium to our aid; and, in order to employ them with fafety, we muft confider how they are modified by the excitement of the cohering forces.

The cohefion of the ftones with each other by cement or otherwife, has, in almoft every fituation, a bad effect. It enables an overload at the crown to break the arch near the haunches, caufing thofe parts to rife, and then to fpread outwards, juft as a Manfarde or Kirb roof would do if the trufs-beam which connects the heads of the lower rafters were fawn through. This can be prevented only by loading that part more than is requifite for equilibrium. It would be prudent to do this to a certain degree, becaufe it is by this cohefion that the crown always becomes the weakeft part of the arch, and fuffers more by any occafional load.

We expect that it will be faid in anfwer to all this, that the cohefion given by the ftrongeft cement that we can employ, nay the cohefion of the ftone itfelf, is a mere nothing in comparifon with the enormous thrufts that are in a ftate of continual exertion in the different parts of an arch. This is very true; but there is another force which produces the fame effect, and which increafes nearly in the proportion that thofe thrufts increafe, becaufe it arifes from them. This is the friction of the ftones on each other. In dry freeftone this friction confiderably exceeds one-half of the mutual preffure. The reflecting reader will fee that this produces the fame effect, in the cafe under confideration, that cohefion heſion would do; for while the arch is in the act of failing, the mutual preſſure of the arch ſtones is acting with full force, and thus produces a friction more than adequate to all the effects we have been ſpeaking of.

30 Proceſs of the breaking of an arch.

When theſe circumſtances are conſidered, we imagine that it will appear that an arch, when expoſed to a great overload on the crown (or indeed on any part), divides, of itſelf, into a number of parts, each of which contains as many arch ſtones as can be pierced (ſo to ſpeak) by one ſtraight line, and that it may then be conſidered as nearly in the ſame ſituation with a polygonal arch of long ſtones butting on each other like ſo many beams in a Norman roof (ſee Roof, n° 49), but without their braces and ties. It tends to break at all thoſe angles; and it is not ſufficiently reſiſted there, becauſe the materials with which the flanks are filled up have ſo little coheſion, that the angle feels no load except what is immediately above it; whereas it ſhould be immediately loaded with all the weight which is diffuſed over the adjoining ſide of the polygon. This will be the caſe, even though the curvelineal arch be perfectly equilibrated. We recollect ſome circumſtances in the failure of a conſiderable arch, which may be worth mentioning. It had been built of an exceedingly ſoft and friable ſtone, and the arch ſtones were too ſhort. About a fortnight before it fell, chips were obſerved to be dropping off from the joints of the archſtones about ten feet on each ſide of the middle, and alſo from another place on one ſide of the arch, about twenty feet from its middle. The maſons in the neighbourhood prognoſticated its ſpeedy downfal, and ſaid that it would ſeparate in thoſe places where the chips were breaking off. At length it fell; but it firſt ſplit in the middle, and about 15 or 16 feet on each ſide, and alſo at the very ſpringing of the arch. Immediately before the fall a ſhivering or crackling noiſe was heard, and a great many chips dropped down from the middle between the two places from whence they had dropped a fortnight before. The joints opened above at thoſe new places above two inches, and in the middle of the arch the joints opened below, and in about five minutes after this the whole came down. Even this movement was plainly diſtinguiſhable into two parts. The crown ſunk a little, and the haunches roſe very ſenſibly, and in this ſtate it hung for about half a minute. The arch ſtones of the crown were hanging by their upper corners. When theſe ſplintered off, the whole fell down.

We apprehend that the procedure of nature was ſomewhat in this manner. Straight lines can be drawn within the archſtones from A (fig. 15.) to B and D, and from thoſe points to C and E. Each of the portions ED, DA, AB, BC, reſiſt as if they were of one ſtone, compoſing a polygonal vault EDABC. When this is overloaded at A, A can deſcend in no other way than by puſhing the angles B and D outwards, cauſing the portions BC, DE, to turn round C and E. This motion muſt raiſe the points B and D, and cauſe the arch ſtones to preſs on each other at their *inner* joints *b* and *d*. This produced the copious ſplintering at theſe joints immediately preceding the total downfal. The ſplintering which happened a fortnight before aroſe from this circumſtance, that the lines AB and AD, along which the preſſure of the overload was propagated, were tangents to the ſoffit of the arch in the points F, H, and G, and therefore the ſtrain lay all on theſe corners of the arch ſtones, and ſplintered a little from off them till the whole took a firmer bed. The ſubſequent phenomena are evident conſequences of this diſtribution and modification of preſſure, and can hardly be explained in any other way; at leaſt not on the theoretical principles already ſet forth: for in this bridge the loads at B and D were very conſiderably greater than what the equilibrium required; and we think that the firſt obſerved ſplintering at H, F, and G, was moſt inſtructive, ſhowing that there was an extraordinary preſſure at the inner joints in thoſe places, which cannot be explained by the uſual theory.

Not ſatisfied with this ſingle obſervation, after this way of explaining it occurred to us, and not being able to find any ſimilar fact on record, the writer of this article got ſome ſmall models of arches executed in chalk, and ſubjected them to many trials, in hopes of collecting ſome general laws of the internal workings of arches which finally produce their downfal. He had the pleaſure of obſerving the above mentioned circumſtances take place very regularly and uniformly, when he overloaded the models at A. The arch always broke at ſome place B conſiderably beyond another point F, where the firſt chipping had been obſerved. This is a method of trial that deſerves the attention both of the ſpeculatiſt and the practitioner.

If theſe reflections are any thing like a juſt account of the procedure of nature in the failure of an arch, it is evident that the ingenious mathematical theory of equilibrated arches is of little value to the engineer. We ventured to ſay as much already, and we reſted a good deal on the authority of Sir Chriſtopher Wren. He was a good mathematician, and delighted in the application of this ſcience to the arts. He was a celebrated architect; and his reports on the various works committed to his charge, ſhow that he was in the continual habit of making this application. Several ſpecimens remain of his own methods of applying them. The roof of the theatre of Oxford, the roof of the cupola of St. Paul's, and in particular the mould on which he turned the inner dome of that cathedral, are proofs of his having ſtudied this theory moſt attentively. He flouriſhed at the very time that it occupied the attention of the greateſt mechanicians of Europe; but there is nothing to be found among his papers which ſhows that he had paid much regard to it. On the contrary, when he has occaſion to deliver his opinion for the inſtruction of others, and to explain to the Dean and Chapter of Weſtminſter his operations in repairing that collegiate church, this great architect conſiders an arch juſt as a ſenſible and ſagacious maſon would do, and very much in the way that we have juſt now been treating it: (See *Account of the Family of Wren*, p. 356, &c.) Supported therefore by ſuch authority, we would recommend this way of conſidering an arch to the ſtudy of the mathematician; and we would deſire the experienced maſon to think of the moſt efficacious methods for reſiſting this tendency of arches to riſe in the flanks. Unfortunately there ſeems to be no preciſe principle to point out the place where this tendency is moſt remarkable.

We are therefore highly pleaſed with the ingenious contrivance of Mr. Mylne, the architect of Blackfriars Bridge in London, by which he determines this point with

Arch. with precision, by making it impossible for the overloaded arch to spring in any other place. Having thus confined the failure to a particular spot, he with equal art opposes a resistance which he believes to be sufficient; and the present condition of that noble bridge, which does not in any place show the smallest change of shape, proves that he was not mistaken. Looking on this work as the first, or at least the second, specimen of masonic ingenuity that is to be seen in the world, we imagine that our readers will be pleased with a particular account of its most remarkable circumstances.

31 Construction of Blackfriars Bridge. Plate III.

The span *k a* (fig. 16.) of the middle arch is 100 feet, and its height OV is 40, and the thickness KV of the crown is six feet seven inches. Its form is nearly elliptical; the part AVZ being an arch of a circle whose centre is C, and radius 56 feet, and the two lateral portions A *k* B and Z *a* E being arches described with a radius of 35 feet nearly. The thickness of the pier at *a b* is 19 feet. The thickness of the arch increases from the crown V to Y, where it is eight or nine feet. All the arch stones have their joints directed to the centres of their curvature. The joints are all joggled, having a cubic foot of hard stone let half way into each. By this contrivance the joints cannot slide, nor can any weight laid on the crown ever break the arch in that part, if the piers do not yield; for a straight line from the middle of KV to the middle of the joint YI is contained within the solid masonry, and does not even come near the inner joints of the arch stones. Therefore the whole resists like one stone, and can be broken only by crushing it. The joint at Z is very nearly perpendicular to a line YF drawn to the outer edge of the foundation of the pier. By this it was intended to take off all tendency of the pressure on the joint *d* Z to overset the pier; for if we suppose, according to the theory of equilibration, that this pressure is necessarily exerted perpendicularly to the joint, its direction passes through the fulcrum at F, round which it is thought that the pier must turn in the act of oversetting. This precaution was adopted, in order to make the arch quite independent of the adjoining arches; so that although any of them should fall, this arch should run no risk.

Still farther to secure the independence of the arch, the following construction was practised to unite it into one mass, which should rise all together. All below the line *a b* is built of large blocks of Portland stone, dovetailed with sound oak. Four places in each course are interrupted by equal blocks of a hard stone called *Kentish rag*, sunk half way in each course. These act as joggles, breaking the courses, and preventing them from sliding laterally.

The portion *a* Y of the arch is joggled like the upper part. The interior part is filled up with large blocks of Kentish rag, forming a kind of coursed rubble-work, the courses tending to the centres of the arch. The under corner of each arch stone projects over the one below it. By this form it takes fast hold of the rubble-work behind it. Above this rubble there is constructed the inverted arch I *c* G of Portland stone. This arch shares the pressure of the two adjoining arches, along with the arch stones in Y *a* and in G *b*. Thus all tend together to compress and keep down the rubble-work in the heart of this part of the pier. This is a very useful precaution; for it often happens, that when the centres of the arches are struck, before the piers are built up to their intended height, the thrust of the arches squeezes the rubble-work horizontally, after the morter has set, but before it has dried and acquired its utmost hardness. Its bond is broken by this motion, and it is squeezed up, and never acquires its former firmness. This is effectually prevented by the pressure exerted by the back of the inverted arch.

Above this counter arch is another mass of coursed rubble, and all is covered by a horizontal course of large blocks of Portland stone, butting against the back of the arch stone ZI and its corresponding one in the adjoining arch. This course connects the feet of the two arches, preserves the rubble work from too great compression, and protects it from soaking water. This last circumstance is important; for if the water which falls on the road-way is not carried off in pipes, it soaks through the gravel or other rubbish, rests on the morter, and keeps it continually wet and soft. It cannot escape through the joints of good masonry, and therefore fills up this part like a funnel.

Supposing the adjoining arch fallen, and all tumbled off that is not withheld by its situation, there will still remain in the pier a mass of about 3500 tons. The weight of the portion VY is about 2000 tons. The directions of the thrusts RY and YF are such, that it would require a load of 4500 tons on VY to overturn the pier round F. This exceeds VY by 2500 tons; a weight incomparably greater than any that can ever be laid on it.

Such is the ingenious construction of Mr. Mylne. It evidently proceeds on the principles recommended above; principles which have occurred to his experience and sagacious mind during the course of his extensive practice. We have seen attempts by other engineers to withstand the horizontal thrusts of the arch by means of counter arches inserted in the same manner as here, but extending much farther over the main arch; but they did not appear to be well calculated for producing this effect. A counter arch springing from any point between Y and V has no tendency to hinder that point from rising by the sinking of the crown; and such a counter arch will not resist the precisely horizontal thrust so well as the straight course of Mr. Mylne.

THE great incorporation of architects who built the cathedrals of Europe departed entirely from the styles of ancient Greece and Rome, and introduced another, in which arcades made the principal part. Not finding in every place quarries from which blocks could be raised in abundance of sufficient size for forming the far-projecting corniches of the Greek orders, they relinquished those proportions, and adopted a style of ornament which required no such projections: and having substituted arches for the horizontal architrave or lintel, they were now able to erect buildings of vast extent with spacious openings, and all this with very small pieces of stone. The form which had been adopted for a Christian temple occasioned many intersections of vaultings, and multiplied the arches exceedingly. Constant practice gave opportunities of giving every possible variety of these intersections, and taught the art of balancing arch against arch in every variety of situation. An art so multifarious, and so much out of the road of

32 Origin of the Gothic arches.

Arch.

of ordinary thought, could not but become an object of fond study to the architects most eminent for ingenuity and invention. Becoming thus the dupes of their own ingenuity, they were fond of displaying it even when not necessary. At last arches became their principal ornament, and a wall or ceiling was not thought dressed out as it should be till filled full of mock arches, crossing and butting on each other in every direction. In this process in their ceilings they found that the projecting mouldings, which we now call the Gothic tracery, formed the chief supports of the roofs. The plane surfaces included between those ribs were commonly vaulted with very small stones, seldom exceeding six or eight inches in thickness. This tracery therefore was not a random ornament. Every rib had a position and direction that was not only proper, but even necessary. Habituated to this scientific arrangement of the mouldings, they did not deviate from it when they ornamented a smooth surface with mock arches; and in none of the highly ornamented *ancient* buildings will we find any false positions. This is by no means the case in many of the modern imitations of Gothic architecture, even by our best architects. Ignorant of the directing principle, or not attending to it, in their stucco work, they please the unskilled eye with pretty radiated figures: but in these we frequently see such abutments of mouldings as would infallibly break the arches, if these mouldings were really performing their ancient office, and supporting a vaulting of considerable extent. Nay, this began even before the Gothic style was finally abandoned. Several instances are to be found in the highly enriched vaultings of New College, and Christ Church in Oxford, in St George's Chapel at Windsor, and Henry VII's Chapel in Westminster.

33 Degeneracy of that style.

We call the middle ages rude and barbarous; but there was surely much knowledge in those who could execute such magnificent and difficult works. The working drafts which were necessary for such varieties of oblique intersections must have required considerable skill, and would at present occupy many very expensive volumes of *masons jewels* and *carpenters manuals*, and the like. All this knowledge was kept a profound secret by the corporation, and on its breaking up we had all to learn again.

There is no appearance, however, that those architects had studied the theory of equilibrated arches. They had adopted an arch which was very strong, and permitted considerable irregularities of pressure—we mean the pointed arch. The very deep mouldings with which it was ornamented, made the arch stones very long in proportion to the span of the arch. But they had studied the mutual thrust of arches on each other with great care; and they contrived to make every invention for this purpose become an ornament, so that the eye *required* it as a necessary part of the building. Thus we frequently see small buildings having buttresses at the sides. These are necessary in a large vaulted building, for withstanding the outward thrust of the vaulting; but they are useless when we have a flat ceiling within. Pinnacles on the heads of the buttresses are now considered as ornaments; but originally they were put there to increase the weight of the buttress: even the great tower, in the centre of a cathedral, which now constitutes its great ornament, is a load almost indispensably necessary, for enabling the four principal columns to withstand the combined thrust of the aisles, of the nave, and transepts. In short, the more closely we examine the ornaments of this architecture, the more shall we perceive that they are essential parts, or derived from them by imitation: and the more we consider the whole style of it, the more clearly do we see that it is all deduced from the relish for arcades, indulged in the extreme, and pushed to the limit of possibility of execution.

34 Great skill of the ablest Gothic architects.

35. Dome or cupola

THERE is another species of arch which must not be overlooked, namely, the DOME or CUPOLA, with all its varieties, which include even the pyramidal steeple or spire.

It is evident that the erection of a dome is also a scientific art, proceeding on the principles of equilibration, and that these principles admit and require the same or similar modifications, in consequence of the cohesion and friction of the materials. At first sight, too, a dome appears a more difficult piece of work than a plain arch; but when we observe potters kilns and glasshouse domes and cones of vast extent, erected by ordinary bricklayers, and with materials vastly inferior in size to what can be employed in common arches of equal extent, we must conclude that the circumstance of curvature in the horizontal direction, or the abutment of a circular base, gives some assistance to the artist. Of this we have complete demonstration in the case of the cone. We know that a vaulting in the form of a pent roof could not be executed to any considerable extent, and would be extremely hazardous, even in the smallest dimensions; while a cone of the greatest magnitude can be raised with very small stones, provided only that we prevent the bottom from flying out, by a hoop, or any similar contrivance. And when we think a little of the matter, we see plainly, that if the horizontal section be perfectly round, and the joints be all directed to the axis, they all equally endeavour to slide inwards, while no reason can be offered why any individual stone should prevail. They are all wedges, and operate only as wedges. When we consider any single course, therefore, we see that it cannot fall in, even though it may be part of a curve which could not stand as a common arch; nay, we see that a dome may be constructed, having the convexity of the curve, by the revolution of which it is formed, turned towards the axis, so that the outline is concave. We shall afterwards find that this is a stronger dome by far than if the convexity were outwards, as in a common arch. We see also that a cone may be loaded on the top with the greatest weight, without the smallest danger of forcing it down, so long as the bottom course is firmly kept from bursting outwards. The stone lanthern on the top of St Paul's cathedral in London weighs several hundred tons, and is carried by a brick cone of eighteen inches thick, with perfect safety, as long as the bottom course is prevented from bursting outwards. The reason is evident: The pressure on the top is propagated along the cone in the direction of the slant side; and, so far from having any tendency to break it in any part, it tends rather to prevent its being broken by any irregular pressure from foreign causes.

36. Of easier construction than a plain arch.

37 Proper construction of octagonal pyramids.

For the same reasons the octagonal pyramids, which form the spires of Gothic architecture, are abundantly firm, although very thin. The sides of the spire of Salisbury

Saliſbury cathedral are not eight inches thick after the octagon is fully formed. It is proper, however, to direct the joints to the axis of the pyramid, and to make the courſing joints perpendicular to the ſlant ſide, becauſe the projecting mouldings which run along the angles are the abutments on which the whole pannel depends. A conſiderable art is neceſſary for ſupporting thoſe pannels or ſides of the octagon which ſpring from the angles of the ſquare tower. This is done by beginning a very narrow pointed arch on the ſquare tower at a great diſtance below the top; ſo that the legs of the arch being very long, a ſtraight line may be drawn from the top of the keyſtone of the arch through the whole arch ſtones of the legs. By this diſpoſition the thruſts ariſing from the weight of theſe four pannels are made to meet on the maſſive maſonry in the middle of the ſides of the tower, at a great diſtance below the ſpringing of the ſpire. This part, being loaded with the great maſs of perpendicular wall, is fully able to withſtand the horizontal thruſt from the legs of thoſe arches. In many ſpires theſe thruſts are ſtill farther reſiſted by iron bars which croſs the tower, and are hooked into pieces of braſs firmly bedded in the maſonry of the ſides.

38 Examples of ſuch conſtruction.

There is much nice balancing of this kind to be obſerved in the highly ornamented open ſpires; ſuch as thoſe of Bruſſels, Mechlin, Antwerp, &c. We have not many of this ſort in Britain. In thoſe of great magnitude, the judicious eye will diſcover that parts, which a common ſpectator would conſider as mere ornaments, are neceſſary for completing the balance of the whole. Tall pinnacles, nay, even pillars carrying entablatures and pinnacles, are to be ſeen ſtanding on the middle of the ſlender leg of an arch. On examination, we find that this is neceſſary, to prevent the arch from ſpringing upwards in that place by the preſſure at the crown. The ſteeple of the cathedral of Mechlin was the moſt elaborate piece of architecture in this taſte in the world, and was really a wonder; but it was not calculated to withſtand a bombardment, which deſtroyed it in 1578.

Such frequent examples of irregular and whimſical buildings of this kind, ſhow that great liberties may be taken with the principle of equilibration without riſk, if we take care to ſecure the baſe from being thruſt outwards. This may always be done by hoops, which can be concealed in the maſonry; whereas, in common arches, theſe ties would be viſible, and would offend the eye.

It is now time to attend to the principle of equilibrium, as it operates in a ſimple circular dome, and to determine the thickneſs of the vaulting when the curve is given, or the curve when the thickneſs is given.

Plate II.

39 Stability of a dome depends on principles

Therefore, let B *b* A (fig. 17.) be the curve which produces the dome by revolving round the vertical axis AD. We ſhall ſuppoſe this curve to be drawn through the middle of all the arch ſtones, and that the courſing or horizontal joints are every where perpendicular to the curve. We ſhall ſuppoſe (as is always the caſe) that the thickneſs KL, HI, &c. of the arch ſtones is very ſmall in compariſon with the dimenſions of the arch. If we conſider any portion HA *b* of the dome, it is plain that it preſſes on the courſe, of which HL is an arch ſtone, in a direction *b* C perpendicular to the joint HI, or in the direction of the next ſuperior element *β b* of the curve. As we proceed downwards, courſe after courſe, we ſee plainly that this direction muſt change, becauſe the weight of each courſe is ſuperadded to that of the portion above it, to complete the preſſure on the courſe below. Through B draw the vertical line BCG, meeting *β b*, produced in C. We may take *b c* to preſs the preſſure of all that is above it propagated in this direction to the joint KL. We may alſo ſuppoſe the weight of the courſe HL united in *b*, and acting on the vertical. Let it be repreſented by *b* F. If we form the parallelogram *b* FGC, the diagonal *b* G will repreſent the direction and intenſity of the whole preſſure on the joint KL. Thus it appears that this preſſure is continually changing its direction, and that the line, which will always coincide with it, muſt be a curve concave downward. If this be preciſely the curve of the dome, it will be an equilibrated vaulting; but ſo far from being the ſtrongeſt form, it is the weakeſt, and it is the limit to an infinity of others, which are all ſtronger than it. This will appear evident, if we ſuppoſe that *b* G does not coincide with the curve A *b* B, but paſſes without it. As we ſuppoſe the arch ſtones to be exceedingly thin from inſide to outſide, it is plain that this dome cannot ſtand, and that the weight of the upper part will preſs it down, and ſpring the vaulting outwards at the joint KL. But let us ſuppoſe, on the other hand, that *b* G falls within the curvelineal element *b* B. This evidently tends to puſh the arch ſtone inward, toward the axis, and would cauſe it to ſlide in, ſince the joints are ſuppoſed perfectly ſmooth and ſlipping. But ſince this takes place equally in every ſtone of this courſe, they muſt all abut on each other in the vertical joints, ſqueezing them firmly together. Therefore, reſolving the thruſt *b* G into two, one of which is perpendicular to the joint KL, and the other parallel to it, we ſee that this laſt thruſt is withſtood by the vertical joints all around, and there remains only the thruſt in the direction of the curve. Such a dome muſt therefore be firmer than an equilibrated dome, and cannot be ſo eaſily broken by overloading the upper part. When the curve is concave upwards, as in the lower part of the figure, the line *b* C always falls below *b* B, and the point C below B. When the curve is concave downwards, as in the upper part of the figure, '*b* C' paſſes above, or without *b* B. The curvature may be ſo abrupt, that even *b*' G' ſhall paſs without '*b* B', and the point G' is above B'. It is alſo evident that the force which thus binds the ſtones of a horizontal courſe together, by puſhing them towards the axis, will be greater in flat domes than in thoſe that are more convex; that it will be ſtill greater in a cone; and greater ſtill in a curve whoſe convexity is turned inwards: for in this laſt caſe the line *b* G will deviate moſt remarkably from the curve. Such a dome will ſtand (having poliſhed joints) if the curve ſprings from the baſe with any elevation, however ſmall; nay, ſince the friction of two pieces of ſtone is not leſs than half of their mutual preſſure, ſuch a dome will ſtand, although the tangent to the curve at the bottom ſhould be horizontal, provided that the horizontal thruſt be double the weight of the dome, which may eaſily be the caſe if it do not riſe high.

40 Different from that of a common arch.

Thus we ſee that the ſtability of a dome depends on very different principles from that of a common arch, and is in general much greater. It differs alſo in another

ther very important circumſtance, viz. that it may be open in the middle: for the uppermoſt courſe, by tending equally in every part to ſlide in toward the axis, preſſes all together in the vertical joints, and acts on the next courſe like the key-ſtone of a common arch. Therefore an arch of equilibration, which is the weakeſt of all, may be open in the middle, and carry at top another building, ſuch as a lanthern, if its weight do not exceed that of the circular ſegment of the dome that is omitted. A greater load than this would indeed break the dome, by cauſing it to ſpring up in ſome of the lower courſes; but this load may be increaſed if the curve is flatter than the curve of equilibration: and any load whatever, which will not cruſh the ſtones to powder, may be ſet on a truncate cone, or on a dome formed by a curve that is convex toward the axis; provided always that the foundation be effectually prevented from flying out, either by a hoop, or by a ſufficient maſs of ſolid pier on which it is ſet. We have mentioned the many failures which happened to the dome of St Sophia in Conſtantinople. We imagine that the thruſt of the great dome, bending the eaſtern arch outward as ſoon as the pier began to yield, deſtroyed the half dome which was leaning on it, and thus, almoſt in an inſtant, took away the eaſtern abutment. We think that this might have been prevented, without any change in the injudicious plan, if the dome had been hooped with iron, as was practiſed by Michael Angelo in the vaſtly more ponderous dome of St Peter's at Rome, and by Sir Chriſtopher Wren in the cone and the inner dome of St Paul's at London. The weight of the latter conſiderably exceeds 3000 tons, and they occaſion a horizontal thruſt which is nearly half this quantity, the elevation of the cone being about 60°. This being diſtributed round the circumference, occaſions a ſtrain on the hoop $= \frac{7}{2 \times 22}$ of the thruſt, or nearly 238 tons. A ſquare inch of the worſt iron, if well forged, will carry 25 tons with perfect ſafety; therefore a hoop of 7 inches broad and $1\frac{1}{2}$ inches thick will completely ſecure this circle from burſting outwards. It is, however, much more completely ſecured; for beſides a hoop at the baſe of very nearly theſe dimenſions, there are hoops in different courſes of the cone which bind it into one maſs, and cauſe it to preſs on the piers in a direction exactly vertical. The only thruſts which the piers ſuſtain are thoſe from the arches of the body of the church and the tranſepts. Theſe are moſt judiciouſly directed to the entering angles of the building, and are there reſiſted with inſuperable force by the whole lengths of the walls, and by four ſolid maſſes of maſonry in the corners. Whoever conſiders with attention and judgment the plan of this cathedral, will ſee that the thruſts of theſe arches, and of the dome, are incomparably better balanced than in St Peter's church at Rome. But to return from this ſort of digreſſion.

41 Excellency of the dome of St Paul's.

42 Theory of the curves proper for domes.

We have ſeen that if b G, the thruſt compounded of the thruſt b C, exerted by all the courſes above HILK, and if the force b F, or the weight of that courſe, be every where coincident with b B, the element of the curve, we ſhall have an equilibrated dome; if it falls within it, we have a dome which will bear a greater load; and if it falls without it, the dome will break at the joint. We muſt endeavour to get analytical expreſſions of theſe conditions. Therefore draw the ordinates $b\,\delta\,b''$, BDB'', C d C''. Let the tangents at b and b'' meet the axis in M, and make MO, MP, each equal to $b\,c$, and complete the parallelogram MONP, and draw OQ perpendicular to the axis, and produce b F, cutting the ordinates in E and e. It is plain that MN is to MO as the weight of the arch HAb to the thruſt $b\,c$ which it exerts on the joint KL (this thruſt being propagated through the courſe HILK); and that MQ, or its equal $b\,e$, or $\delta\,d$, may repreſent the weight of the half AH.

Let AD be called x, and DB be called y. Then $b\,e = \dot{x}$, and e C $= \dot{y}$ (becauſe $b\,c$ is in the direction of the element $\beta\,b$). It is alſo plain, that if we make $\dot{y}$ conſtant, BC is the ſecond fluxion of x, or BC $= \ddot{x}$, and $b\,e$ and BE may be conſidered as equal, and taken indiſcriminately for $\dot{x}$. We have alſo b C $= \sqrt{\dot{x}^2 + \dot{y}^2}$. Let d be the depth or thickneſs HI of the arch ſtones. Then $d\sqrt{\dot{x}^2 + \dot{y}^2}$ will repreſent the trapezium HL: and ſince the circumference of each courſe increaſes in the proportion of the radius y, $d\,y\sqrt{\dot{x}^2 + \dot{y}^2}$ will expreſs the whole courſe. If $\int$ be taken to repreſent the ſum or aggregate of the quantities annexed to it, the formula will be analogous to the fluent of a fluxion, and $\int d\,y\sqrt{\dot{x}^2 + \dot{y}^2}$ will repreſent the whole maſs, and alſo the weight of the vaulting, down to the joint HI. Therefore we have this proportion $\int d\,y\sqrt{\dot{x}^2 + \dot{y}^2} : d\,y\sqrt{\dot{x}^2 + \dot{y}^2} = b\,e : b\,\text{F}, = b\,e : \text{CG}, = \delta d : \text{CG}, = \dot{x} : \text{CG}$. Therefore $\text{CG} = \frac{d\,y\,\dot{x}\sqrt{\dot{x}^2 + \dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2 + \dot{y}^2}}$.

If the curvature of the dome be preciſely ſuch as puts it in equilibrium, but without any mutual preſſure in the vertical joints, this value of OG muſt be equal to CB, or to $\ddot{x}$, the point G coinciding with B. This condition will be expreſſed by the equation $\frac{d\,y\,\dot{x}\sqrt{\dot{x}^2 + \dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2 + \dot{y}^2}} = \ddot{x}$, or, more conveniently, by $\frac{d\,y\sqrt{\dot{x}^2 + \dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2 + \dot{y}^2}} = \frac{\ddot{x}}{\dot{x}}$. But this form gives only a tottering equilibrium, independent of the friction of the joints and the coheſion of the cement. An equilibrium, accompanied by ſome firm ſtability, produced by the mutual preſſure of the vertical joints, may be expreſſed by the formula $\frac{d\,y\sqrt{\dot{x}^2 + \dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2 + \dot{y}^2}} > \frac{\ddot{x}}{\dot{x}}$, or by $\frac{d\,y\sqrt{\dot{x}^2 + \dot{y}^2}}{\int d\,y\sqrt{\dot{x}^2 + \dot{y}^2}} = \frac{\ddot{x}}{\dot{x}} + \frac{\dot{t}}{t}$, where t is ſome variable poſitive quantity, which increaſes when x increaſes.

Arch. creaſes. This laſt equation will alſo expreſs the equilibrated dome, if t be a conſtant quantity, becauſe in this caſe $\frac{\dot{t}}{t}$ is $= o$.

Since a firm ſtability requires that $\frac{dy\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}$ ſhall be greater than $\ddot{x}$, and CG muſt be greater than CB: Hence we learn, that figures of too great curvature, whoſe ſides deſcend too rapidly, are improper. Alſo, ſince ſtability requires that we have $\frac{dy\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\ddot{x}}$ greater than $\int dy\sqrt{\dot{x}^2+\dot{y}^2}$, we learn that the upper part of the dome muſt not be made very heavy. This, by diminiſhing the proportion of b F to b C, diminiſhes the angle $c\,b$ G, and may ſet the point G above B, which will infallibly ſpring the dome in that place. We ſee here alſo, that the algebraic analyſis expreſſes that peculiarity of dome-vaulting, that the weight of the upper part may even be ſuppreſſed.

The fluent of the equation $\frac{dy\sqrt{\dot{x}^2+\dot{y}^2}}{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}=\frac{\ddot{x}}{\dot{x}}+\frac{\dot{t}}{t}$ is moſt eaſily found. It is $L\int dy\sqrt{\dot{x}^2+\dot{y}^2}=L\dot{x}+Lt$, where L is the hyperbolic logarithm of the quantity annexed to it. If we conſider $\dot{y}$ as conſtant, and correct the fluent ſo as to make it nothing at the vertex, it may be expreſſed thus, $L\int dy\sqrt{\dot{x}^2+\dot{y}^2}-La=L\dot{x}-L\dot{y}+Lt$. This gives us $L\frac{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}{a}=L\frac{\dot{x}}{\dot{y}}t$, and therefore $\frac{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}{a}=t\frac{\dot{x}}{\dot{y}}$.

This laſt equation will eaſily give us the depth of vaulting, or thickneſs d of the arch, when the curve is given. For its fluxion is $\frac{dy\sqrt{\dot{x}^2+\dot{y}^2}}{a}=\frac{\dot{t}\dot{x}+t\ddot{x}}{\dot{y}}$, and $d=\frac{a\dot{t}\dot{x}+at\ddot{x}}{y\dot{y}\sqrt{\dot{x}^2+\dot{y}^2}}$, which is all expreſſed in known quantities; for we may put in place of t any power or function of x or of y, and thus convert the expreſſion into another, which will ſtill be applicable to all ſorts of curves.

Inſtead of the ſecond member $\frac{\ddot{x}}{\dot{x}}+\frac{\dot{t}}{t}$, we might employ $\frac{p\ddot{x}}{\dot{x}}$, where p is ſome number greater than unity. This will evidently give a dome having ſtability; becauſe the original formula $\frac{dy\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}$ will then be greater than $\ddot{x}$. This will give $d=\frac{pa\dot{x}^{p-1}\ddot{x}}{y\dot{y}^p\sqrt{\dot{x}^2+\dot{y}^2}}$. Each of theſe forms has its advantages when applied to particular caſes. Each of them alſo gives $d=\frac{a\ddot{x}}{y\dot{y}\sqrt{\dot{x}^2+\dot{y}^2}}$ when the curvature is ſuch as is in preciſe equilibrium. And, laſtly, if d be conſtant, that is, if the vaulting be of uniform thickneſs, we obtain the form of the curve, becauſe then the relation of $\ddot{x}$ to $\dot{x}$ and to $\dot{y}$ is given. Arch.

The chief uſe of this analyſis is to diſcover what curves are improper for domes, or what portions of given curves may be employed with ſafety. Domes are generally built for ornament; and we ſee that there is great room for indulging our fancy in the choice. All curves which are concave outwards will give domes of great firmneſs: They are alſo beautiful. The Gothic dome, whoſe outline is an undulated curve, may be made abundantly firm, eſpecially if the upper part be convex and the lower concave outwards.

The chief difficulty in the caſe of this analyſis ariſes from the neceſſity of expreſſing the weight of the incumbent part, or $\int dy\sqrt{\dot{x}^2+\dot{y}^2}$. This requires the meaſurement of the conoidal ſurface, which, in moſt caſes, can be had only by approximation by means of infinite ſerieſes. We cannot expect that the generality of practical builders are familiar with this branch of mathematics, and therefore will not engage in it here; but content ourſelves with giving ſuch inſtances as can be underſtood by ſuch as have that moderate mathematical knowledge which every man ſhould poſſeſs who takes the name of engineer.

The ſurface of any circular portion of a ſphere is very eaſily had, being equal to the circle deſcribed with a radius equal to the chord of half the arch. This radius is evidently $=\sqrt{x^2+y^2}$.

In order to diſcover what portion of a hemiſphere may be employed (for it is evident that we cannot employ the whole) when the thickneſs of the vaulting is uniform, we may recur to the equation or formula $\frac{dy\dot{x}\sqrt{\dot{x}^2-\dot{y}^2}}{\ddot{x}}=\int dy\sqrt{\dot{x}^2+\dot{y}^2}$. Let a be the radius of the hemiſphere. We have $\dot{x}=\frac{ay\dot{y}}{\sqrt{a^2-y^2}}$, and $\ddot{x}=\frac{a^2\dot{y}^2}{\overline{a^2-y^2}|^{\frac{3}{2}}}$. Subſtituting theſe values in the formula, we obtain the equation $y^2\sqrt{a^2-y^2}=\int\frac{a^2y\dot{y}}{\sqrt{a^2-y^2}}$. We eaſily obtain the fluent of the ſecond member $=a^3-a^2\sqrt{a^2-y^2}$, and $y=a\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$. Therefore if the radius of the ſphere be 1, the half breadth of the dome muſt not exceed $\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$, or 0,786, and the height will be 618. The arch from the vertex is about 51° 49′. Much more of the hemiſphere cannot ſtand, even though aided by the cement, and by the friction of the courſing joints. This laſt circumſtance, by giving connection to the upper parts, causes the whole to press more vertically on the course below, and thus diminishes the outward thrust; but it at the same time diminishes the mutual abutment of the vertical joints, which is a great cause of firmness in the vaulting. A Gothic dome, of which the upper part is a portion of a sphere not exceeding 45° from the vertex, and the lower part is concave outwards, will be very strong, and not ungraceful.

43 Dome of St Peter's at Rome.

But the public taste has long rejected this form, and seems rather to select more elevated domes than this portion of a sphere; because a dome, when seen from a small distance, always appears flatter than it really is. The dome of St Peter's is nearly an ellipsoid externally, of which the longer axis is perpendicular to the horizon. It is very ingeniously constructed. It springs from the base perpendicularly, and is very thick in this part. After rising about 50 feet, the vaulting separates into two thin vaultings, which gradually separate from each other. These two shells are connected together by thin partitions, which are very artificially dovetailed in both, and thus form a covering which is extremely stiff, while it is very light. Its great stiffness was necessary for enabling the crown of the dome to carry the elegant stone lanthern with safety. It is a wonderful performance, and has not its equal in the world; but it is an enormous load in comparison with the dome of St. Paul's, and this even independent of the difference of size. If they were of equal dimensions, it would be at least five times as heavy, and is not so firm by its gravity; but as it is connected in every part by iron bars (lodged in the solid masonry, and well secured from the weather by having lead melted all round them), it bids fair to last for ages, if the foundations do not fail.

Plate II.

If a circle be described round a centre placed anywhere in the transverse axis AC (fig. 18. N° 1.) of an ellipse, so as to touch the ellipse in the extremities B, *b*, of an ordinate, it will touch it internally, and the circular arch B *a b* will be wholly within the elliptical arch BA *b*. Therefore, if an elliptical and a spherical vaulting spring from the same base, at the same angle with the horizon, the spherical vaulting will be within the elliptical, will be flatter and lighter, and therefore the weight of the next course below will bear a greater proportion to the thrust in the direction of the curve; therefore the spherical vaulting will have more stability. On the contrary, and for similar reasons, an oblate elliptical vaulting is preferable to a spherical vaulting springing with the same inclination to the horizon. (Fig. 18. N° 2.)

44 Dimensions of the best form of a dome.

Persuaded, that what has been said on the subject convinces the reader that a vaulting perfectly equilibrated throughout is by no means the best form, provided that the base is secured from separating, we think it unnecessary to give the investigation of that form, which has a considerable intricacy; and shall content ourselves with merely giving its dimensions. The thickness is supposed uniform. The numbers in the first column of the table express the portion of the axis counted from the vertex, and those of the second column are the lengths of the ordinates.

465,4	1000	2602	1520	7260	1800

The curve delineated in fig. 19. is formed according to these dimensions, and appears destitute of gracefulness; because its curvature changes abruptly at a little distance from the vertex, so that it has some appearance of being made up of different curves pieced together. But if the middle be occupied by a lanthern of equal, or of smaller weight, this defect will cease, and the whole will be elegant, nearly resembling the exterior dome of St Paul's in London.

It is not a small advantage of dome-vaulting that it is lighter than any that can cover the same area. If, moreover, it be spherical, it will admit considerable varieties of figure, by combining different spheres. Thus, a dome may begin from its base as a portion of a large hemisphere, and may be broken off at any horizontal course, and then a similar or a greater portion of a smaller sphere may spring from this course as a base. It also bears being intersected by cylindrical vaultings in every direction, and the intersections are exact circles, and always have a pleasing effect. It also springs most gracefully from the heads of small piers, or from the corners of rooms of any polygonal shape; and the arches formed by its intersections with the walls are always circular and graceful, forming very handsome spandrels in every position. For these reasons Sir Christopher Wren employed it in all his vaultings, and he has exhibited many beautiful varieties in the transepts and the aisles of St Paul's, which are highly worthy of the observation of architects. Nothing can be more graceful than the vaultings at the ends of the north and south transepts, especially as finished off in the fine inside view published by Gwynn and Wale. 45 Advantages of dome-vaulting.

We conclude this article with observing, that the connection of the parts, arising from cement and from friction, has a great effect on dome-vaulting. In the same way as in common arches and cylindrical vaulting, it enables an overload on one place to break the dome in a distant place. But the resistance to this effect is much greater in dome-vaulting, because it operates all round the overloaded part. Hence it happens that domes are much less shattered by partial violence, such as the falling of a bomb or the like. Large holes may be broken in them without much affecting the rest; but, on the other hand it greatly diminishes the strength which should be derived from the mutual pressure in the vertical joints. Friction prevents the sliding in of the arch stones which produces this mutual pressure in the vertical joints, except in the very highest courses, and even there 46 Effects of cement and friction in dome vaulting.

there it greatly diminishes it. These causes make a great change in the form which gives the greatest strength: and as their laws of action are but very imperfectly understood as yet, it is perhaps impossible, in the present state of our knowledge, to determine this form with tolerable precision. We see plainly, however, that it allows a greater deviation from the best form than the other kind of vaulting, and domes may be made to rise perpendicular to the horizon at the base, although of no great thickness; a thing which must not be attempted in a plane arch. The immense addition of strength which may be derived from hooping, largely compensates for all defects; and there is hardly any bounds to the extent to which a very thin dome vaulting may be carried, when it is hooped or framed in the direction of the horizontal courses. The roof of the Halle du Bled at Paris is but a foot thick, and its diameter is more than 200, yet it appears to have abundant strength. It is, on the whole, a noble specimen of architecture.

47 The iron bridge at Sunderland described.

We must not conclude this article without taking notice of that magnificent and elegant arch which has been erected in cast iron at Weremouth, near Sunderland, in the county of Durham. The inventor and architect is Rowland Burdon, Esq; one of the representatives of that county in the present Parliament.

This arch is a segment of a circle whose diameter is about 444 feet. The span or cord of the arch is 236 feet, and its versed sine or spring is 34 feet. It springs at the elevation of 60 feet from the surface of the river at low water, so that vessels of 200 or perhaps 300 tons burden may pass under it in the middle of the stream, and even 50 feet on each side of it.

The sweep of the arch consists of a series of frames of cast iron, which butt on each other, in the same manner as the voussoirs of a stone arch. One of these frames or blocks (as we shall call them in future) is represented in fig. 1. as seen in front. It is cast in one piece; and consists of three pieces or arms BC, BC, BC, the middle one of which is two feet long, the upper being somewhat more, and the lower somewhat less, because their extremities are bounded by the radius drawn from the centre of the arch. These arms are four inches square, and are connected by other pieces KL, of such length that the whole length of the block is five feet in the direction of the radius. Each arm has a flat groove on each side, which is expressed by the darker shading, three inches broad and three-fourths of an inch deep. A section of this block, through the middle of KL, is represented by the light-shaded part BBB, in which the grooves are more distinctly perceived. These grooves are intended for receiving flat bars of malleable iron, which are employed for connecting the different blocks with each other. Fig. 2. represents two blocks united in this manner. For this purpose each arm has two square bolt-holes. The ends of the arms being nicely trimmed off, so that the three ends butt equally close on the ends of the next block; and the bars of hammered iron being also nicely fitted to their grooves, so as to fill them completely, and have their bolt-holes exactly corresponding to those in the blocks, they are put together in such a manner that the joints or meetings of the malleable bars may fall on the middle between the bolt-holes in the arms. Flat headed bolts of wrought iron

Plate IV.

are then put through, and keys or forelocks are driven through the bolt-tails, and thus all is firmly wedged together, binding each arm between two bars of wrought iron. These bars are of such length as to connect several blocks.

In this manner a series of about 125 blocks are joined together, so as to form the precise curve that is intended. This series may be called a rib, and it stands in a vertical plane. The arch consists of six of these ribs, distant from each other five feet. These ribs are connected together so as form an arch of 32 feet in breadth, in the following manner.

Fig. 3. represents one of the bridles or cross pieces which connect the different ribs, as it appears when viewed from below. It is a hollow pipe of cast iron, four inches in diameter, and has at each end two projecting shoulders, pierced with a bolt hole near their extremities, so that the distance between the bolt-holes in the shoulders of one end is equal to the distance between the holes in the arms of the blocks, or the holes in the wrought iron bars. In the middle of the upper and of the underside of each end may be observed a square prominence, more lightly shaded than the rest. These projections also advance a little beyond the flat of the shoulders, forming between them a shallow notch, about an inch deep, which receives the iron of the arms, where they butt on each other, and thus gives an additional firmness to the joint. The manner in which the arms are thus grasped by these notches in the bridles is more distinctly seen in fig. 2. at the letter H in the middle of the upper rail.

The rib having been all trimmed and put together, so as to form the exact curve, the bolts are all taken out, and the horizontal bridles are then set on in their places, and the bolts are again put in and made fast by the forelocks. The bolts now pass through the shoulders of the bridles, through the wrought iron bars, and through the cast iron arm that is between them, and the forelocks bind all fast together. The manner in which this connection is completed is distinctly seen in fig. 2. which shows in perspective a double block in front, and a single block behind it. The butting joints of the two front blocks are at the letters E, E, E; the holes in the shoulders of the horizontal cross pieces are at H.

48 Its construction simple and judicious,

This construction is beautifully simple and very judicious. A vast addition of strength and of stiffness is procured by lodging the wrought iron bars in grooves formed in the cast iron rails; and for this purpose it is of great importance to make the wrought iron bars fill the grooves completely, and even to be so tight as to require the force of the forelocks to draw them home to the bottom of the grooves. There can be no doubt but that this arch is able to withstand an enormous pressure, as long as the abutments from which it springs do not yield. Of this there is hardly any risk, because they are masses of rock, faced with about four or five yards (in some places only) of solid block masonry. The mutual thrusts of the frames are all in the direction of the rails, so that no part bears any transverse strain. We can hardly conceive any force that can overcome the strength of those arms by pressure or crushing them. The manner in which the frames are connected into one rib, effectually secures the butting joints from slipping; and the accuracy with which the whole can be executed, ed, ſecures us againſt any warping or deviation of a rib from the vertical plane.

But when we conſider the prodigious ſpan of this arch, and reflect that it is only five feet thick, it ſhould ſeem that the moſt perfect equilibration is indiſpenſably neceſſary. It is but like a film, and muſt be ſo ſupple that an overload on any part muſt have a great tendency to bend it, and to cauſe it to riſe in a diſtant part; and this effect is increaſed by the very firmneſs with which the whole ſticks together. The overloaded part acts on a diſtant part, tending to break it with all the energy of a long lever. This can be prevented only by means of the ſtiffneſs of the diſtant part. It is very true, the arch cannot break in the extrados except by tearing aſunder the wrought iron bars which connect the blocks along the upper rail, and each of theſe requires more than a hundred tons to tear it aſunder; yet an overload of five tons on any rib at its middle will produce this ſtrain at twenty feet from the ſides, ſuppoſing the ſides held firm in their poſition. It were deſirable therefore that ſomething were done to ſtiffen the arch at the ſides, by the manner of filling up the ſpandrels, or ſpace between the arch and the road-way. This is filled up in a manner that is extremely light and pleaſing to the eye, namely, by large caſt iron circles, which touch the extrados of the arch and touch the road-way. The road-way reſts on them as on ſo many hoops, while they reſt on the back of the arch, and alſo touch each other laterally. We cannot think that this contributes to the ſtrength of the arch; for theſe hoops will be eaſily compreſſed at the points of contact, and, changing their ſhape, will oppoſe very little reſiſtance. We think that this part of the arch might have been greatly ſtiffened and ſtrengthened, by connecting it with the road way by truſſed frames, in the ſame way that a judicious carpenter would have framed a roof. If a ſtrong caſt iron pillar had been made to reſt on the arch at about 20 feet from the impoſt, and been placed in the direction of a radius, the top of this pillar might have been connected by a diagonal bar of wrought iron with the impoſt of the arch, and with the crown of the arch by another ſtring or bar of the ſame materials. Theſe two ties would cauſe the radial pillar to preſs ſtrongly on the back of the arch, and they muſt be torn aſunder before it could bend in that place in the ſmalleſt degree. Suppoſing them of the ſame dimenſions as the bars in the arms, their poſition would give them near ten times the force for reſiſting the ſtrain produced by an overload on the crown.

49 Though in one particular capable, perhaps of improvement.

This beautiful arch contains only 260 tons of iron, of which about 55 are wrought iron. The ſuperſtructure is of wood, planked over a-top. This floor is covered with a coating of chalk and tar, on which is laid the materials for the carriage road, conſiſting of marle, limeſtone, and gravel, with foot-ways of flag-ſtones at the ſides. The weight of the whole did not exceed a thouſand tons; whereas the lighteſt ſtone arch which could have been erected would have weighed fifteen thouſand. It was turned on a very light but ſtiff ſcaffolding, moſt judiciouſly conſtructed for the preſervation of its form, and for allowing an uninterrupted paſſage for the numerous ſhips and ſmall craft which frequent the buſy harbour of Sunderland. The mode of framing the arch was ſo ſimple and eaſy, that it was put up in ten days! without an accident; and when all was finiſhed, and the ſcaffolding removed, the arch did not ſenſibly change its form. The whole work was executed in three years, and coſt about L. 26,000.

ARCHITECTURE is an art of ſo much importance, and capable of ſo many embelliſhments, as to have employed the attention and talents of men of ſcience in almoſt every age, and in every country. It is generally thought to have been carried to the utmoſt perfection among the Greeks and Romans; and it has been the aim of the moſt eminent architects of modern times to imitate with fidelity the buildings of thoſe accompliſhed nations. There is, however, another ſpecies of architecture, which was introduced into Europe in the middle ages, and is of ſuch a nature as to ſtrike every unprejudiced obſerver with admiration and aſtoniſhment. The architecture to which we allude has been called, perhaps with little propriety,

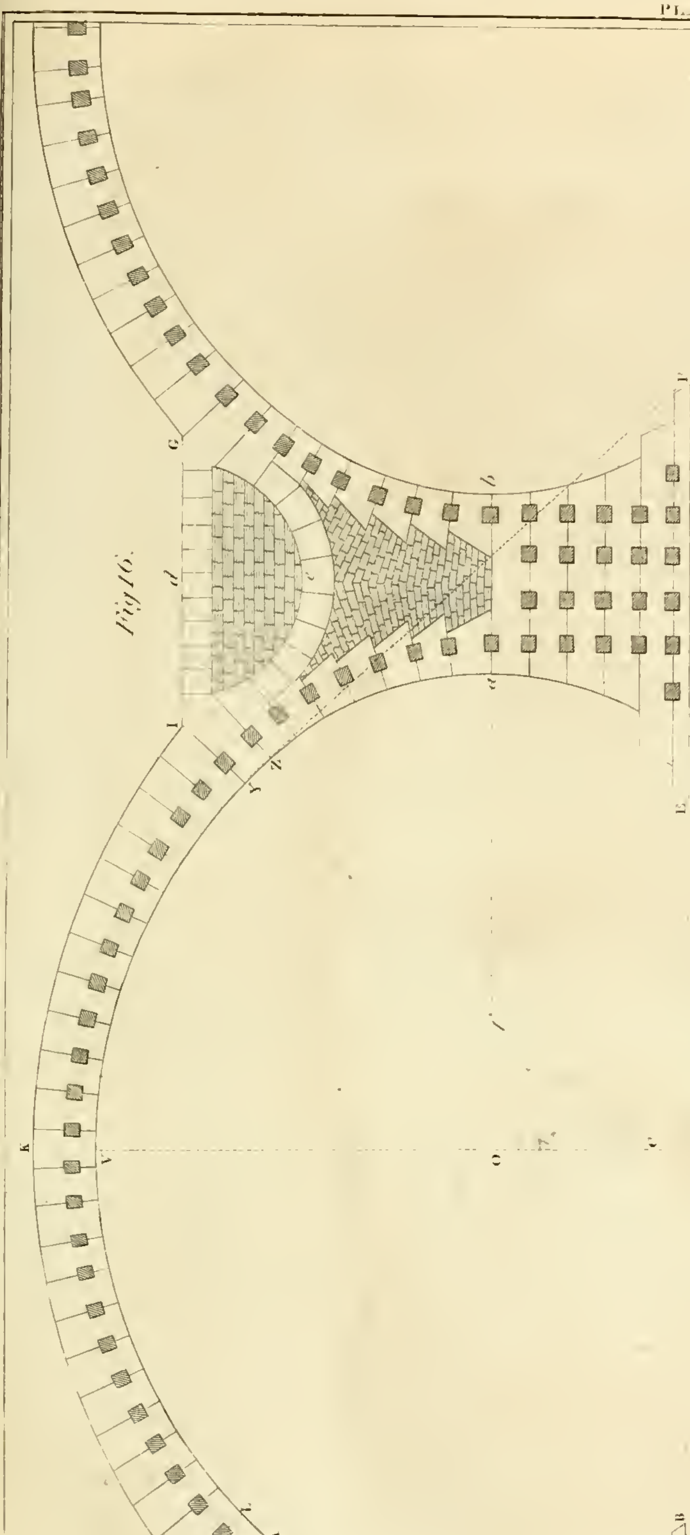
Gothic Architecture. It is that which is to be viewed in all our ancient cathedrals, and in other large buildings, which have been erected from the middle of the 12th to the beginning of the 16th century. That ſuch edifices have been conſtructed on principles of ſcience, has been ſhown elſewhere (ſee Roof, *Encycl.* and Arch, in this *Suppl.*): but a queſtion ſtill preſents itſelf to the inquiſitive mind, "How came ſuch ſtructures to be thought of by a people whom we are accuſtomed to call ignorant and barbarous?" This queſtion has occupied the attention of many ingenious men, who have attributed the Gothic ſtyle of building, ſome to neceſſity, and others to an imitation of the works of nature. That, where materials are bad, larger edifices can be erected in the Gothic than in the Grecian ſtyle, has been made ſufficiently evident in the articles to which we have referred; and that neceſſity is the parent of invention, is an adage which has been too long received to be now called in queſtion. But whence came the peculiarities of the Gothic ornaments in building, the pointed arch, and the double row of cluſtered pillars compoſed of ſlender ſhafts, which, reaching from the ground almoſt to the roof of the building, are there ſpread out in all directions, forming the ribs or *groins* of a vaulted roof?

The moſt ſatisfactory ſolution of this queſtion which we have ſeen, is in a memoir publiſhed in the fourth volume of the Tranſactions of the Royal Society of Edinburgh, by Sir James Hall, Bart. with whoſe permiſſion the following abſtract is laid before our readers.

"Although the connection between beauty and utility be ſtill involved in ſuch obſcurity, that we are unable to decide concerning the univerſality of that connection, of one thing we are certain, that, in a work intended to anſwer ſome uſeful purpoſe, whatever viſibly counteracts that purpoſe always occaſions deformity. Hence it is, that, even where ornament is principally intended, the oſtenſibly uſeful object of the work, if it have any ſuch, muſt be provided for, in the firſt place, in preference to every other conſideration.

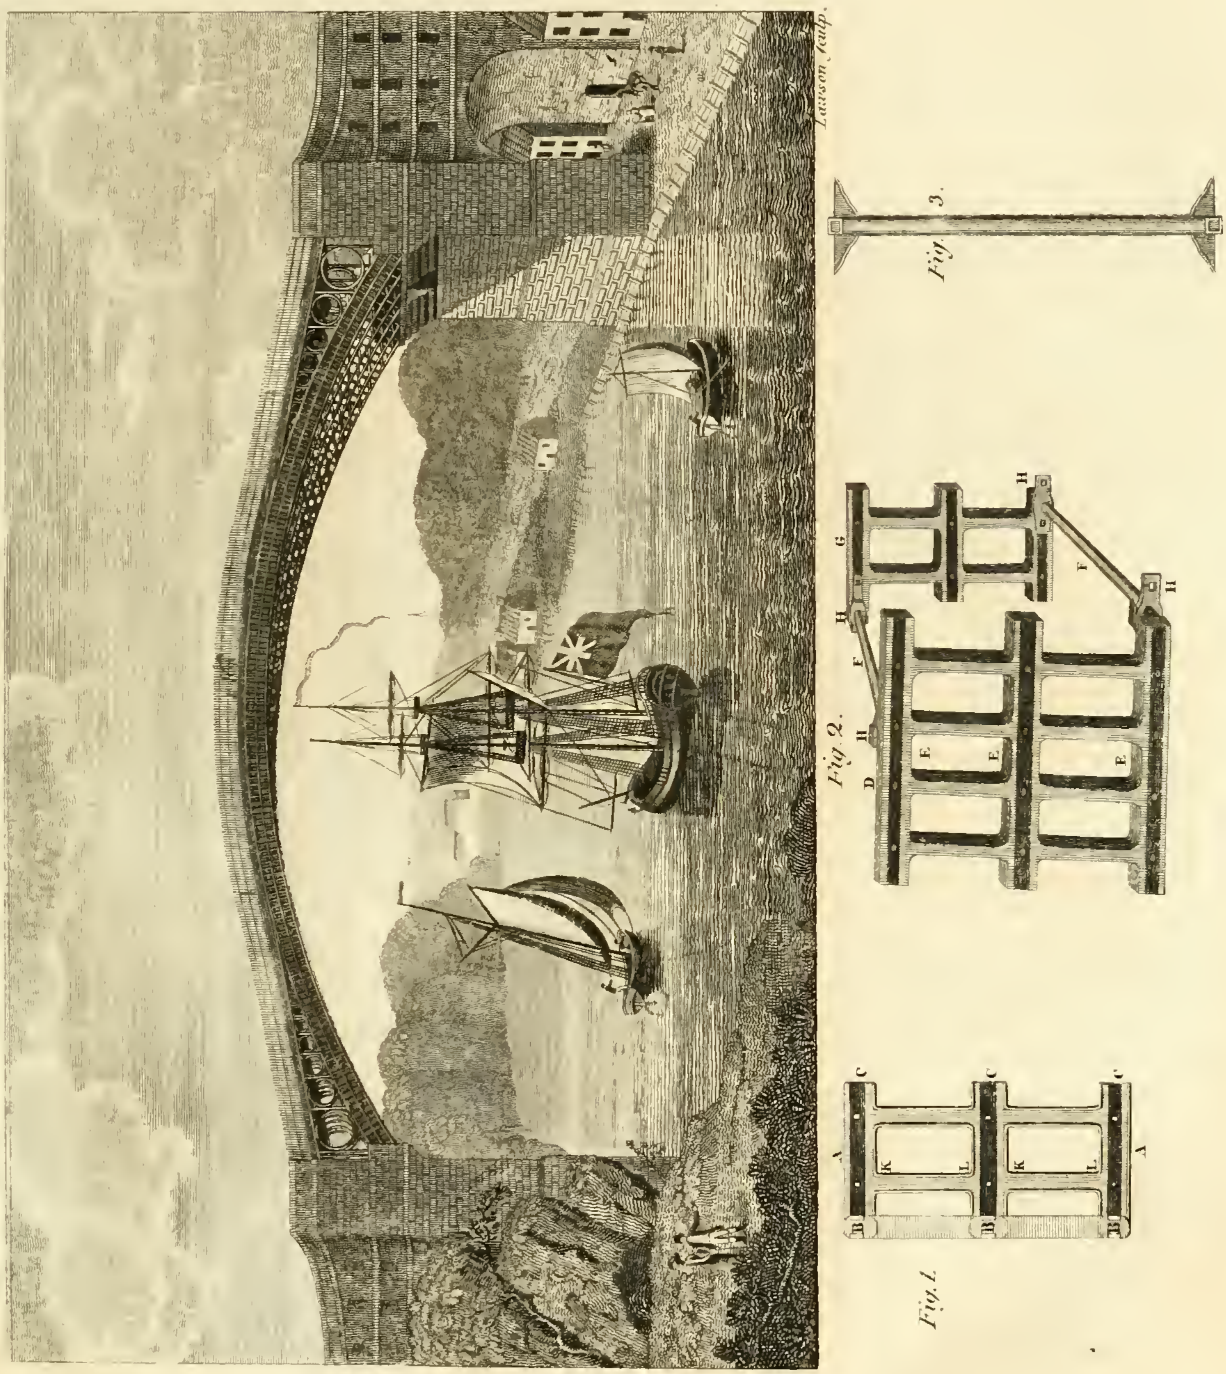
"But in moſt uſeful works, ſome parts occur, the ſhape of which is quite indifferent with reſpect to the propoſed utility, and which, therefore, the artiſt is at liberty to execute as he pleaſes: a liberty which has opened a wide field to the taſte and invention of ingenious men of every age and country, who have turned their attention to the compoſition of ornaments; and

Fig. 16.



MALE ANHINGA

IRON BRIDGE.



Architecture.

whose exertions have been more or less influenced by the state of civilization in which they lived. It would seem, however, if we may judge by those various efforts, that little has been effected by mere human ingenuity; since we see that recourse has been had, almost universally, to nature, the great and legitimate source of beauty; and that ornament has been attained by the imitation of objects, to which she has given a determinate and characteristic form.

"Where the materials employed are themselves possessed of variety and elegance, the attainment of this object requires little or no alteration of their natural forms. Thus cups are made of shells, of cocoa nuts, or of ostrich eggs; the character and beauty of which depend upon the natural form of the materials: and in the case of the bottles used by the Roman Catholic pilgrims an example occurs of an utensil, in which the natural form has undergone little or no variation, since it consists of the hard outward skin of a gourd, of the same shape in which it grew upon the plant (A). This last class of forms has been introduced, by imitation, into works composed of shapeless materials. Thus we have silver cups in the form of those made of shells, and fruit-dishes of stone ware in the form of baskets.

"As stone is not naturally possessed of any peculiar shape, and as the useful object proposed, by structures formed of it, may be accomplished in various ways, very great latitude is left to the invention of the artist. We see, accordingly, that in every country where much refinement has been introduced, great pains have been bestowed in ornamenting stone buildings with figures representing various natural objects; whilst the building itself has been executed in imitation of a structure, composed of materials which naturally possess a determinate and characteristic form. Such was the method followed by the architects of ancient Greece, who constructed temples, and other public edifices, in imitation of a rustic fabric, composed of square beams, supported upon round posts or stems of trees, and who derived the numerous ornaments of that beautiful style from circumstances which would naturally take place in such a structure.

"A faint and distant resemblance, however, of the original, has generally been found to answer all the end proposed by the imitation; a resemblance, which may sometimes be traced in the general distribution of the edifice, sometimes in its minute parts, and not unfrequently in both.

"But the forms of nature thus introduced have been greatly modified by those of masonry. For though stone is by nature shapeless, yet, in the course of practice, many peculiar forms have been long established, and currently employed, in working it; such as straight lines, plain surfaces, square angles, and various mouldings used to soften the effect of abrupt terminations: all of which, originating in motives of mechanical convenience, and of simple ornament, had, in very early times, been appropriated to masonry, and considered as essential in every finished work of stone; so that, when the imitation of nature was introduced, these masonic forms still maintained their ground, and, being blended with the forms of nature, the two classes reciprocally modified each other.

"This combination of art with nature, of which we see the most perfect example in the Corinthian capital, produces what are called architectonic forms, in which the variety of nature, being subjected to the regularity of art, the work acquires that peculiar character which, in a natural object, we consider as offensive, under the name of *formality*; but which, in architecture, we admire as a beauty, under the name of *symmetry*: thus, we reprobate the formality of an avenue, and praise the symmetry of a colonnade.

"Such is the nature of architectonic imitation; a device which probably originated in accident, but to which architecture is indebted for its highest attainments."

As the stone edifices of ancient Greece were constructed in imitation of a wooden fabric, composed of square beams laid at right angles on round posts or stems of trees, Sir James conceives that the Gothic fabrics with pointed arches have been executed in imitation of a rustic dwelling, constructed in the following manner: Suppose a set of round posts driven firmly into the ground in two opposite rows, the interval between the neighbouring posts in the same row being equal to that between the rows, and each post being raised above the ground to a height equal to three of those intervals: then a set of long and flexible rods of willow being applied to each post, let them be thrust into the ground at its base, and bound to it by two tyings, one near the ground, and another at two-thirds of its height; the rods being left loose from this last point upwards, and free to be moved in any direction. Let three rods be connected with each outside corner post, and five with each of the others, and let their position be such as to cover the inside of the post, so that when seen from between the rows the lower part of each post shall be concealed from the view, and present the appearance of a bundle of rods (fig 1.) Plate V.

Things being thus disposed, the skeleton of a thatched roof may be formed by means of the loose ends of the rods. A rod from one of the posts being so bent as to meet a similar one from the post immediately opposite to it, in the middle of the space between them, let the two rods be made to cross each other, and let them be bound together at their crossing (fig. 2.), and we shall have the exact form of the Gothic arch. The same being done with each pair of opposite posts, and a set of pointed arches being formed, let them be connected together by means of a straight pole laid upon the forks of the crossing rods, and bound to each of them, as in fig. 3: then let a loose rod be brought from each of any two contiguous posts in the same row, so as to form a pointed arch, similar to that just described, and nearly of the same height. This being done with every two contiguous posts (fig. 4.), and a new set of pointed arches being thus produced, standing opposite to

(A) "Even in this case, however, the natural form undergoes a certain degree of modification, by the device employed to produce the neck of the bottle. The fruit, while small and tender, is surrounded with a string, which remaining during its growth, prevents the part, thus bound, from swelling with the rest."

to each other in pairs, let each pair be bound by a horizontal pole lying on the opposite forks, and crossing the longitudinal pole described above.

"Two of the rods of each corner post, and three of those of each of the others, being thus disposed of, we have one of each corner post and two of each middle post still to employ, which is done as follows: A pair of these unoccupied rods being brought from any two posts which stand diagonally to each other, and made to meet in the middle, not as in the first case crossing in an angle, but side by side, forming a semicircle, and joined together after the manner of a hoop; and the same being done with every pair of diagonal posts (fig. 5.), the whole rods will have been employed.

"In this manner a frame would be constructed fit to support thatch or other covering; and such a one has probably been often used. It would seem, however, that, for the sake of strength, the number of rods has been increased in each cluster, by the introduction, between every two of them, of an additional rod, which rising with them to the roof, still continues its middle position, as they spread asunder, and meets the horizontal pole at an intermediate point. This is shown in fig. 6. which is drawn with its covering of thatch; and, from the imitation of a dwelling so constructed, we may easily trace the three leading characteristics of Gothic architecture, the pointed arch, the clustered column, and the branching roof, as exhibited in fig. 7."

Upon the same principles Sir James Hall, with much ingenuity, accounts for the peculiar forms of the Gothic door, the Gothic window, and the pointed spire: but it is not our intention to supersede the necessity of having recourse to his memoir, but to excite the desire of our readers to peruse as well that paper as a larger work which he promises on the same subject, and in which we doubt not but they will find both entertainment and instruction. We shall conclude this article, therefore, with an experimental proof of the justness of his hypothesis.

In the greater part of our late attempts at Gothic architecture, it is allowed by every man of taste that we have failed. The failure is to be accounted for by the buildings having been constructed upon no consistent principle, applicable to every part of them, but upon a servile copying of ancient edifices, of which the structure was little understood by the copiers. Sir James Hall, however, by applying his theory to practice, has constructed a building in this style, which has far surpassed, he says, his own expectation, and has certainly gained the approbation of every man of taste and science by whom we have had occasion to hear it mentioned. "A set of posts of ash, about three inches in diameter, were placed in two rows, four feet asunder, and at the interval of four feet in the rows; then a number of slender and tapering willow rods, ten feet in length, were applied to the posts, and, in the manner which we have described, formed into a frame, which being covered with thatch, produced a very substantial roof, under which a person can walk with ease.

"This little structure exhibits, in miniature, all the characteristic features of the Gothic style. It is in the form of a cross, with a nave, a choir, and a north and south transept. The thatch, being so disposed on the frame as not to hide the rods of which it is composed, they represent accurately the pointed and semicircular arches, and all the other peculiarities of a groined roof."

ARCTUS, a name given by the Greeks to two constellations of the northern hemisphere, by the Latins called *Ursa Major* and *Minor*, and by us the *Greater* and *Lesser Bear*.

ARGYLE, a township in Washington county, New-York, on the E. bank of Hudson River, containing 2341 inhabitants, inclusive of 14 slaves. In the state census of 1796, there appears to be 404 electors.—*Morse*.

ARGYLE, a township in Shelburne county, Nova-Scotia, settled by Acadians and Scotch.—*ib.*

ARIES *Kill*, a small creek which runs northerly into Mohawk River, 2½ miles W. from Schoharie River, in New-York.—*ib.*

BINARY ARITHMETIC. See *Binary Arithmetic*, Encycl.

Duodecimal Arithmetic, is that which proceeds from 12 to 12, or by a continual subdivision according to 12. This is greatly used by most artificers in calculating the quantity of their work; as bricklayers, carpenters, painters, tilers, &c.

Harmonical Arithmetic, is so much of the doctrine of numbers as relates to the making the comparisons, reductions, &c. of musical intervals.

Arithmetic of infinites, is the method of summing up a series of numbers, of which the number of terms is infinite. This method was first invented by Dr. Wallis, as appears by his treatise on that subject; where he shows its uses in geometry, in finding the areas of superficies, the contents of solids, &c. But the method of fluxions, which is a kind of universal arithmetic of infinites, performs all these more easily, as well as a great many other things, which the former will not reach.

Logistical Arithmetic, a name sometimes employed for the arithmetic of sexagesimal fractions, used in astronomical computations. Shakerly, in his *Tabulæ Britannicæ*, has a table of logarithms adapted to sexagesimal fractions, which he calls *logistical logarithms*; and the expeditious arithmetic, obtained by means of them, he calls *logistical arithmetic*. The term *logistical arithmetic*, however, or *logistics*, has been used by Vieta and others for the rules of computations in algebra.

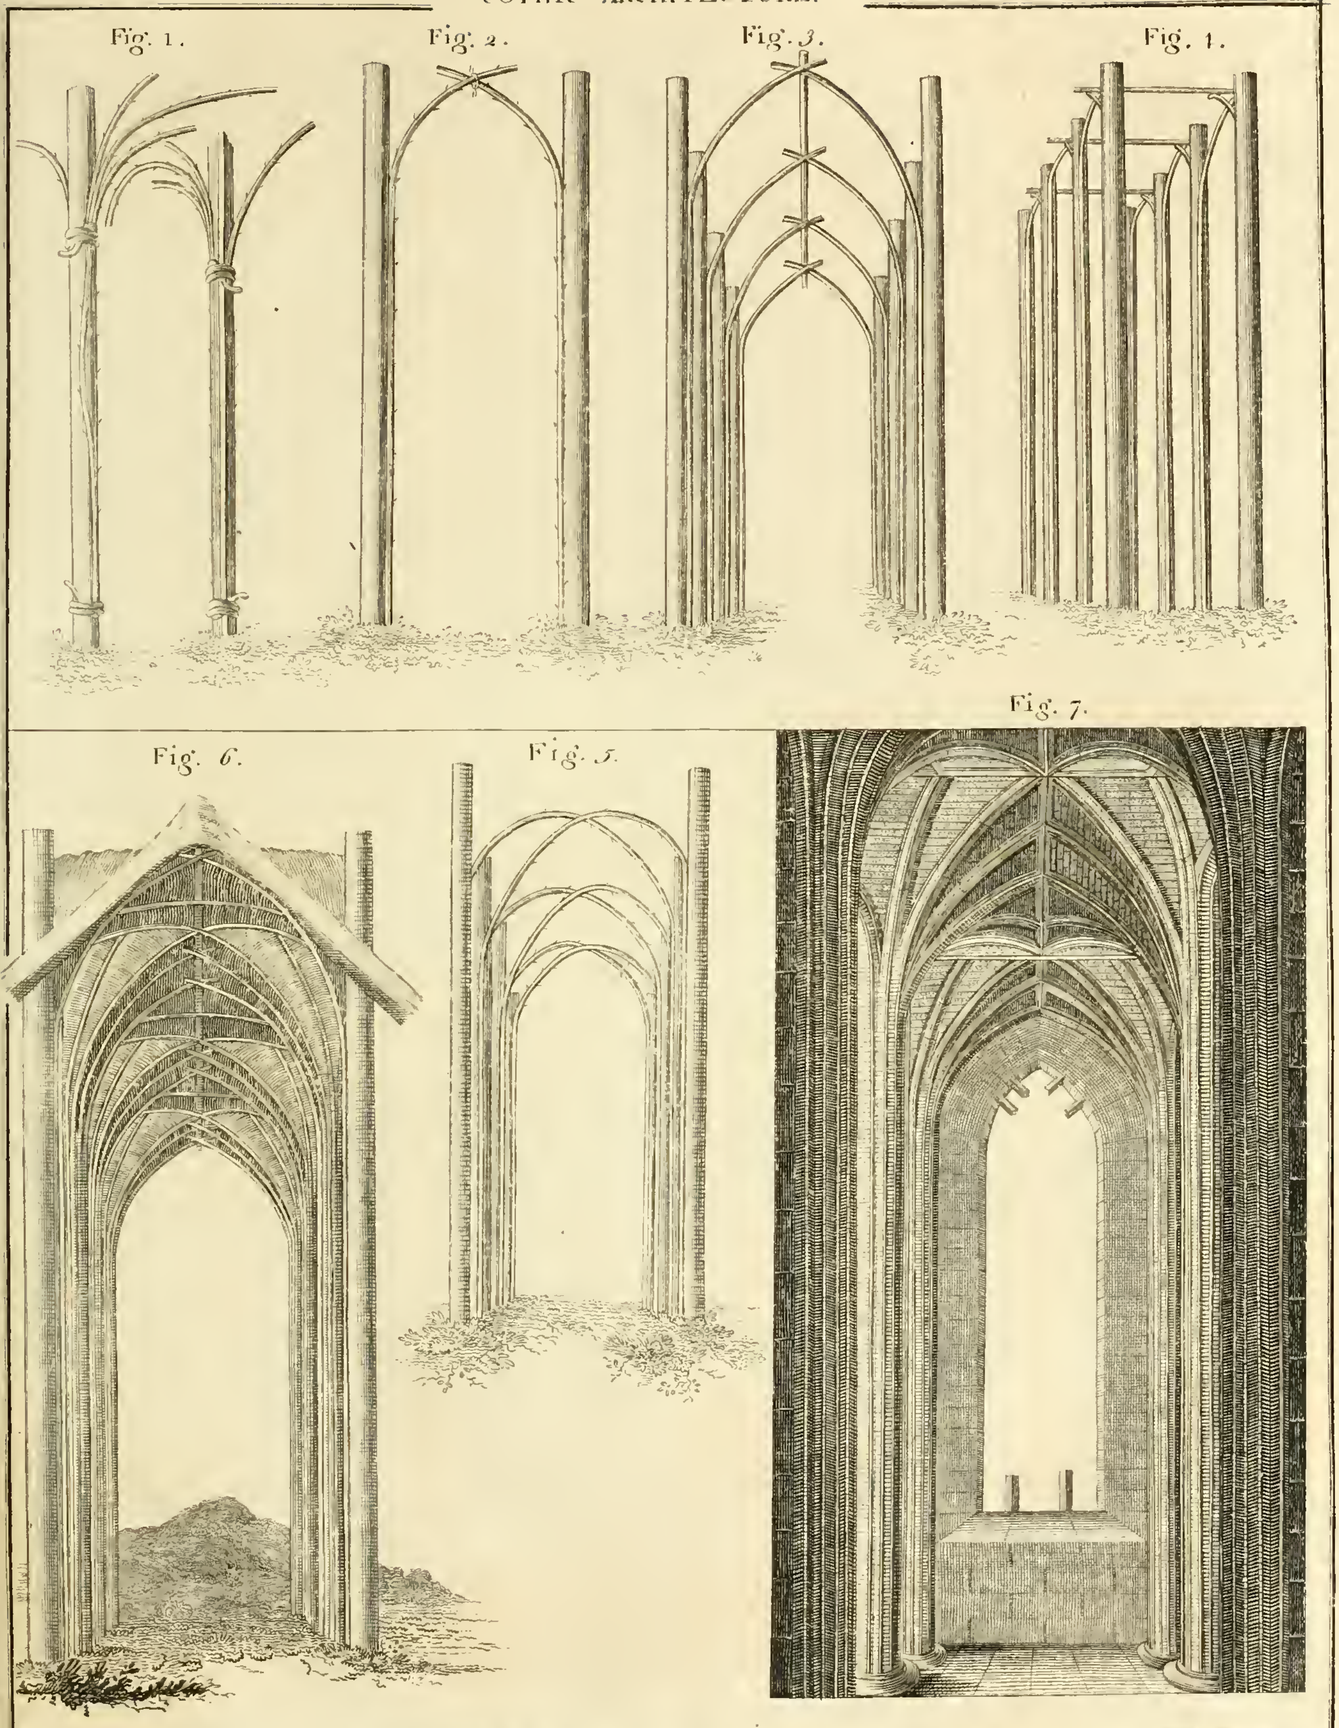
Political Arithmetic. See *Political Arithmetic*, Encycl.

Sexagesimal Arithmetic. See Arithmetic *(Hist.)* Encycl.

Tetractic Arithmetic, is that in which only the four characters, 0, 1, 2, 3, are used. A treatise of this kind of arithmetic is extant by Erhard or Echard Weigel. But both this and binary arithmetic are little better than curiosities, especially with regard to practice; as all numbers are much more compendiously and conveniently expressed by the common decuple scale.

Universal Arithmetic, is the name given by Newton to the science of algebra; of which he left at Cambridge an excellent treatise, being the text-book drawn up for the use of his lectures, while he was professor of mathematics in that university.

ARITHMETICAL complement, of a logarithm, is what the logarithm wants of 10·00000, &c. and the easiest way to find it is, beginning at the left



J. [illegible] Sc.

left hand, to fubtract every figure from 9, and the laft from 10.

ARLINGTON, a townfhip in Bennington county, Vermont, 12 miles N. from Bennington. It has 991 inhabitants.—*Morse.*

ARRACIFFE, a port town of Brazil, in the captainfhip of Pernambaco; efteemed the ftrongeft in all Brazil. The port confifts of a fuburb, in which are fome large houfes, and repofitories for ftores; and is built upon a narrow paffage, with a caftle to defend the entrance. Notwithftanding which, James Lancafter entered the harbour in 1595, with 7 Englifh veffels, and made himfelf mafter of the town and caftle, where he continued a month, and carried off immenfe plunder; but fince that time, the Portuguefe have rendered it almoft inacceffible to enemies. Lat. 8. 20. S. long. 36. 10. W.—*ib.*

ARRAYAL De Porate, a town in Brazil, fituated on the W. fide of Para River, below the junction of its two great branches.—*ib.*

ARROWSIKE, an ifland in the diftrict of Maine, parted from Parker's Ifland by a fmall ftrait. It is within the limits of George-Town, and contains nearly $\frac{1}{7}$ of its inhabitants, and has a church. It contains about 20,000 acres of land, including a large quantity of falt marfh.—*ib.*

ARSACIDES, *the Iflands of the*, the name given by M. de Surville, in 1769, to Solomon's Iflands, on account of the barbarous character of their inhabitants, particularly at Port Praflin. Thefe iflands were vifited by Mr. Shortland in 1788, and by him called New-Georgia.—*ib.*

ARTEDI (John), was born in the year 1705, in the province of Angermania, in Sweden. From nature he inherited an ardent paffion for all branches of natural hiftory, but he excelled moft in that branch of it which is termed *ichthyology*. In 1724 he went to ftudy at the univerfity of Upfal, where fome years afterwards he gained the friendfhip of the immortal Linnæus, who narrates the principal events of his life in the following animated terms.

"In 1728 (fays Linnæus) I came from Lund to Upfal. I wifhed to devote myfelf to medicine. I inquired who, at that univerfity, excelled moft for his knowledge: every one named Artedi. I was impatient to fee him. I found him pale, and in great diftrefs for the lofs of his father, with his thin hair neglected. He refembled the portrait of Ray the naturalift. His judgment was ripe, his thoughts profound, his manners fimple, his virtues antique. The converfation turned upon ftones, plants, animals. I was enchanted with his obfervations, equally ingenious and new; for at the very firft he was not afraid to communicate them to me with the utmoft franknefs. I defired his friendfhip, he afked mine. From that moment we formed a friendfhip; which we cultivated with the greateft ardour for feven months at Upfal. I was his beft friend, and I never had any who was more dear to me. How fweet was that intimacy! With what pleafure did we fee it increafe from day to day! The difference, even of our characters, was ufeful to us. His mind was more fevere, more attentive; he obferved more flowly, and with greater care. A noble emulation animated us. As I defpaired of ever becoming as well inftructed in chemiftry as he, I abandoned it; he alfo ceafed to ftudy botany with the fame ardour, to which I had devoted myfelf in a particular manner. We continued thus to ftudy different branches of fcience; and when one of us excelled the other, he acknowledged him for his mafter. We difputed the palm in ichthyology; but foon I was forced to yield, and I abandoned that part of natural hiftory to him, as well as the amphibia. I fucceeded better than he in the knowledge of birds and infects, and he no longer tried to excel in thefe branches. We marched together as equals in lithology, and the hiftory of quadrupeds. When one of us made an obfervation, he communicated it to the other: fcarce a day paffed in which one did not learn from the other fome new and interefting particular. Thus emulation excited our induftry, and mutual affiftance aided our efforts. In fpite of the diftance of our lodgings, we faw each other every day. At laft I fet out for Lapland; he went to London. He bequeathed to me his manufcripts and his books.

"In 1735 I went to Leyden, where I found Artedi. I recounted my adventures; he communicated his to me. He was not rich, and therefore was unable to be at the expence of taking his degrees in phyfic. I recommended him to Seba, who engaged him to publifh his work on fifhes. Artedi went to join him at Amfterdam.

"Scarcely had I finifhed my *Fundamenta Botanica*. I communicated it to him; he let me fee his *Philofophia Ichthyologica*. He propofed to finifh as quickly as poffible the work of Seba, and to put the laft hand to it. He fhowed me all his manufcripts which I had not feen: I was preffed in point of time, and began to be impatient as being detained fo long. Alas! if I had known this was the laft time I fhould fee him, how fhould I have prolonged it!

"Some days after, as he returned to fup with Seba, the night being dark, he fell into the canal. Nobody perceived it, and he perifhed. Thus died, by water, this great ichthyologift, who had ever delighted in that element."

Of the works of this eminent naturalift there have been two editions, of which the former was publifhed by Linnæus in 1738, and the latter by Dr. Walbaum of Lubeck, in the years 1788, 1789, and 1792. This edition, which is by much the moft valuable, is in three volumes 4to; of which the firft contains the hiftory of the fcience of ichthyology, commencing feveral years before the Chriftian era, and coming down to the prefent times. The fecond prefents to the reader the *Philofophia Ichthyologica* of Artedi, improved by Walbaum, who was benefited by the writings of Monro, Camper, Kætfeuter and others. Here alfo are added tables containing the fyftem of fifhes by Ray, Dale, Schaeffir, Linnæus, Gowan, Scopola, Klein, and Gronovius. The third volume, which completes the collection of Artedi's works, contains the technical definitions of the fcience. After the generic and individual characters, come the names and Latin phrafes of Artedi; the fynonymes of the beft naturalifts; the vulgar names in Englifh, German, Swedifh, Ruffian, Danifh, Norwegian, Dutch, and Samoyed; the feafon and the countries where every kind is found, their varieties, their defcription, and obfervations. The modern difcoveries, even to our own times, are added; fo that in this

this part is collected the obfervations of Gronovius, Brunich, Penant, Forfter, Klein, Bloch, Gmelin, Haffelquift, Brouffonet, Lefke, Buifh, Linnæus, and other great examiners of nature.

ARTHUR KULL, or *Newark Bay*, on the coaft of New-Jerfey, is formed by the union of Paffaic and Hackinfack Rivers.—*Morse.*

ARUNDEL, a townfhip in York county, diftrict of Maine, containing 1458 inhabitants. It lies between Cape Porpoife, and Biddeford on the N. E. on Saco River, 21 miles N. E. from York, and 96 N. E. from Bofton.—*ib.*

ASANGARO, a jurifdiction under the bifhop of Cufco, in Peru, South America, 50 leagues from that city: numbers of cattle are bred here. There are fome filver mines in the N. E. part of it; and it produces papas, quinoas, and canaguas. Of the two laft they make chicha, as others do from maize.—*ib.*

ASHBURNHAM, formerly *Dorchefter Canada*, lies in Worcefter county, Maffachufetts, 30 miles N. of Worcefter, and 55 from Bofton, was incorporated in 1765, and contains 951 inhabitants. It ftands upon the height of land E. of Connecticut River, and W. of Merrimack, on the banks of Little Naukheag. In this townfhip, is a white fand, equal in finenefs to that at Cape Ann, and which, it is judged, would make fine glafs.—*ib.*

ASHBY, a townfhip in Middlefex county, Maffachufetts, 50 miles N. W. from Bofton, containing 751 inhabitants.—*ib.*

ASHCUTNEY, or *Afacutney*, a mountain in Vermont, being partly in the townfhips of Windfor and Weathersfield, and oppofite Claremont on Sugar River, in New-Hampfhire ftate. It is 2031 feet above the fea, and 1732, above high water in Connecticut River, which glides by its E. fide.—*ib.*

ASHFIELD, a townfhip in Hampfhire county, Maffachufetts, about 15 miles N. W. of Northampton, and 117 W. from Bofton, containing 1459 inhabitants.—*ib.*

ASHFORD, a townfhip in Windham county, Connecticut, fettled from Marlborough in Maffachufetts, and was incorporated in 1710. It lies about 38 miles north-eafterly from Hartford, and 76 fouthwefterly from Bofton.—*ib.*

ASHMOT, the principal harbour in Ifle Madame, which is dependent on Cape Breton. See *Breton Cape*.—*ib.*

ASHUELOT, or *Afhwillet*, a fmall river, having a number of branches, whofe moft diftant fource is at the N. end of the Sunapee Mountains, in New-Hampfhire. It runs fouth-wefterly through part of Chefhire county. Below Winchefter it runs W. by N. and empties into Connecticut River, at Hinfdale.—*ib.*

ASPOTAGOEN *Mountain.* This high land lies on the promontory that feparates Mahone from Margaret's Bay, on the coaft of Nova-Scotia. It is feen at a great diftance from the offing, and is the land generally made by the fhips bound from Europe and the Weft-Indies to Halifax. The fummit is about 500 feet above the level of the fea.—*ib.*

ASSENEPOWALS, a lake weftward of Chriftianaux Lake, and through which its waters run into Albany River, in New South Wales.—*ib.*

ASSINIBOILS, or *Affiniboels*, a river and lake in the N. W. part of North America. The river is faid to rife in the Mountain of Bright Stones, runs N. E. into Lake Ouinipique in N. lat. 51 ½ W. long. 106.—*ib.*

The lake is placed in fome maps in the 52d deg. of N. lat. and 96th of W. long. It has communication with Chriftianaux Lake, on the eaftward, which fends its waters to James Bay. Near thefe, lie the countries of the Chriftianaux, and Kiris, called alfo Killiftins.—*ib.*

ASSUMPTION, an epifcopal city, in the province of Paraguay, in the E. divifion of Paraguay or La Plata in S. America. It ftands on the eaftern bank of a river of its name, a little above the place where the Picolmaga falls into it; having Villa Rica on the N. and La Plata on the S. and is nearer the fouthern, than the Pacific ocean; but not far from the middle of that part of the continent. It was built by the Spaniards in 1538, and is remarkable for its healthy fituation, as well as for the number of its inhabitants, and the rich and fruitful territory in which it ftands; which produces a great variety of native and exotic fruits, in the higheft perfection. Here are feveral hundred Spanifh families, defcendants of the flower of the gentry who fettled in this place; while the dregs of their countrymen removed to other parts. There are likewife a number of Meftizos and Mulattoes. The city lies about 50 leagues above the confluence of the Paraguay and Parana, where the former begins to be called, the River de la Plata. Near the city is a lake, noted for having in the middle of it a rock, which fhoots up to a prodigious height like an obelifk. Lat. 26. S. long. 57. 40. W.—*ib.*

ASSUMPTION *River*, in New-York, falls in from the E. into Lake Ontario, after a N. W. and W. courfe of about 28 miles, 5 miles S. E. from Pl. Gaverfe.—*ib.*

ASTRONOMY

IS a fcience which has been cultivated from the earlieft ages, and is converfant about the moft fublime objects of inquiry which can employ the mind of man. It has accordingly been treated at great length in the Encyclopædia; but, in the opinion of fome of the moft judicious readers of that work, the compiler of the fyftem which is there delivered has failed in his attempt to give a perfpicuous and connected view of the fcience in its prefent ftate of improvement. This defect it is our duty to remedy. Our object, therefore, in this fupplementary article, will be to bring into one point of view the phyfical fcience which may be derived from the confideration of the celeftial motions; that is, to deduce from the general laws of thofe motions the inferences with refpect to their fuppofed caufes, which conftitute the philofophy of the aftronomer.

1 Object of this article.

The

The cauſes of all phenomena are not only inferred from the phenomena, but are characteriſed by them; and we can form no notion of their nature but what we conceive as competent to the phenomena themſelves. The aſtronomical phenomena are aſſumed to be the motions of the *bodies*, which we call the *ſun*, the *planets*, the *comets*, &c. The notion which we expreſs by the word *body* in the preſent caſe, is ſuppoſed to be the ſame with that which we form of other objects around us, to which we give the ſame name; ſuch as ſtones, ſticks, the bodies of animals, &c. Therefore the notion which we have of the cauſes of the celeſtial motions muſt be the ſame with that which we have of the cauſes of motion in thoſe more familiar bodies. All men ſeem to have agreed in giving the name FORCES, or MOVING FORCES, to the cauſes of thoſe familiar motions. This is a figurative or metaphorical term. The true and original meaning of it is, the exertion which we are conſcious of making when we ourſelves put other bodies in motion. Force, when uſed without figure, always ſignifies the exertion of a living and acting thing. We are more intereſted in thoſe productions of motion than in any other, and our recollections of them are more numerous. Hence it has happened that we uſe the ſame term to expreſs the cauſe of bodily motion in general, and ſay that a magnet has force, that a ſpring has force, that a moving body has force.

2 Metaphorical uſe of the term *force*.

Our own force is always exerted by the intervention of our own body; and we find that the ſame exertion by which we move a ſtone, enables us to move another man; therefore we conceive his body to reſemble a ſtone in this reſpect, and that it alſo requires the exertion of force to put it in motion. But when we reflect on our employment of force for producing motion in a body, we find ourſelves puzzled how to account for the motion of our own bodies. Here we perceive no intervening exertion but that of willing to do it; yet we find that we cannot move it as we pleaſe. We alſo find that a greater motion requires a greater exertion. It is therefore to this exertion that the reflecting man reſtrains the term *force*; and he acknowledges that every other uſe of it is metaphorical, and that it is a reſemblance in the ultimate effect alone which diſpoſes us to employ the term in ſuch caſes: but we find no great inconvenience in the want of another term.

We farther find, that our exertion is neceſſary, not only for producing motion where there was none before, but alſo for producing any change of motion; and accurate obſervation ſhows us, that the ſame force is required for changing a motion by any given quantity, as for producing that quantity where there was none before.

Laſtly, we are conſcious of exerting force when we reſiſt the exerted force of another; and that an exertion, perfectly ſimilar to this, will prevent ſome very familiar tendencies to motion in the bodies around us: thus an exertion is neceſſary for carrying a weight, that is, for preventing the fall of that weight.

All theſe reſemblances between the effects of our forcible exertions and the changes of motion which accompany the meeting, and ſometimes the mere vicinity of other bodies, juſtify us in the uſe of this figurative language. The reſemblance is found to be the more perfect as we obſerve it with more care, and, in ſhort, appears to be without exception. Bodies are therefore ſaid to *act* on each other, to *reſiſt* each other, to *reſiſt a change of motion*, &c.

Therefore, wherever we obſerve a change of motion, we infer the exiſtence and exertion of a changing force; and we infer the direction of that exertion from the direction of the change; and the quantity of the exertion, or intenſity of the force, from the quantity of the change.

The ſtudy of the cauſes of the celeſtial motions is therefore hardly different from the ſtudy of the motions themſelves; ſince the agency, the kind, and the degree of the moving force, are immediate inferences from the exiſtence, the kind, and the quantity of the change of motion.

3 Our notion of a moving power.

Our notion of a moving power is that of a power which produces motion, that is, a ſucceſſive change of place. Continuation of the motion produced is therefore involved in the very notion of the production of motion; therefore the continued agency of the moving power, or of any power, is not neceſſary for the continuation of the motion. Motion is conſidered as a ſtate or condition of the body; there is not any exertion of power therefore in the continuation of motion: But every change is indicative of a changing cauſe; and when the change is the ſame, in all its circumſtances, the cauſe is neceſſarily conceived to be the ſame or equal.

The condition of a body, in reſpect of motion, can differ from that of another equal body only in its direction and in its velocity. If the directions are the ſame, the difference of conditions can only be in the difference of velocity. One body has a determination, by which it would deſcribe ten feet uniformly in a ſecond, if nothing changed this determination; the other has a determination, by which it would deſcribe twenty feet in a ſecond. Each of theſe determinations are ſuppoſed to be the effects of forces acting ſimilarly in every reſpect. Therefore theſe determinations are the only meaſures of theſe two forces; that is, moving forces are conceived by us as having the proportion of the velocities which they produce in a body by acting in a manner perfectly ſimilar.

4 Meaſure of moving forces.

We can conceive a force acting equally or unequally. If we ſuppoſe it to act equally or uniformly, we ſuppoſe that in equal times it produces equal effects; that is, equal determinations, or equal changes of determination. We have no other notion of equality or uniformity of action. Therefore it muſt produce equal augmentations or diminutions of velocity in equal times; therefore it muſt produce an *uniformly* accelerated or retarded motion. Uniformly accelerated or retarded motion is, therefore, the mark of uniform or unvaried action. In ſuch a motion, the changes of velocity are proportional to the times from the beginning of the action; and if the motion has begun from reſt, the whole acquired velocities are proportional to the times from the beginning of the motion. In this caſe, the ſpaces deſcribed are as the ſquares of the times from the beginning of the motion; and thus we arrive at an oſtenſible mark of the unvaried action of a moving force, viz. ſpaces increaſing in the duplicate ratio of the times: for ſpace and time are all that we can immediately obſerve in any motion that is continually varying; the velocity or determination is only an inference, on the

5 Accelerated motion the mark of unvaried action;

 ſuppoſition

fuppofition that the motion continues unchanged for fome time, or that all action ceafes for fome time.

This abftract reafoning is perfectly agreeable to every phenomenon that we can obferve with diftinctnefs. Thus we cannot, or at leaft we do not, conceive the weight of a body to vary its action during the fall. We confider this weight as the caufe of the fall—as the moving force—and we conceive it to act uniformly. And, in fact, a body falling freely, defcribes fpaces which are proportional, not to the times, but to the fquares of the times, and the fall is a motion uniformly accelerated. In like manner, the motion of a body rifing in the air, in oppofition to gravity, is uniformly retarded.

6 And gives a meafure of the acquired velocity.

This kind of motion alfo gives us a certain meafure of the acquired velocity, although there is not, in fact, any fpace obferved to be uniformly defcribed during any time whatever. In this motion we know that the final determination, produced by the accumulated or continued action of the unvaried force, is fuch that the body would defcribe uniformly twice the fpace which it has defcribed with the accelerated motion.

And it is by this method that we obtain the fimpleft meafure of any moving force, and can compare it with another. If we obferve that by the action of one force (known to be uniform by the fpaces being proportional to the fquares of the times) ten feet have been defcribed in a fecond, and that by the uniform action of another force eighty feet are defcribed in two feconds, we know that the laft force is double of the firft: for in the fecond motion, 80 feet were defcribed in two feconds, and therefore 20 feet of this were defcribed in the firft fecond (becaufe the motion is uniformly accelerated); and at the end of a fecond, the firft body had a determination by which it would defcribe 20 feet uniformly in a fecond; and the fecond body had acquired a determination by which it would have defcribed 40 feet uniformly in the next fecond, had not the moving force continued to act on it, and made it really defcribe 60 feet with an accelerated motion.

Becaufe halves have the fame proportions with the units of which they are the halves, it is plain that we may take the fpaces, defcribed in equal times with motions uniformly accelerated, as meafures of the forces which have produced thofe motions. The velocities generated are, however, the beft meafures.

7 Meafure of the velocity produced by action not uniform.

When the actions of forces are not uniform, it is more difficult to learn what is the meafure of the velocity produced by their accumulated action. But it can be determined with equal accuracy; that is, we can determine what is the velocity which *would have been produced* by the uniform action of the force during the fame time, and therefore we obtain a meafure of the force. Mathematicians are farther able to demonftrate, that if forces vary their continued action in any manner whatever, the proportion of the fpaces defcribed by two bodies in equal times approaches nearer and nearer to the proportion of the fpaces which they would defcribe in thofe times by the uniform action of the forces, as the times themfelves are fmaller; and therefore whenever we can point out the ultimate ratio of the fpaces defcribed in equal times, thefe times being diminifhed without end, we obtain the ratio of the forces.

Motions may be changed, not only in quantity, by acceleration or retardation, but alfo in direction, by deflecting a body from its former direction. When a body, moving uniformly in the direction AB (fig. 1.), has its motion changed in the point B, and, inftead of defcribing BC uniformly in the next moment with the former velocity, defcribes BD uniformly in that moment, it is plain that the motion BD will be the fame, whether the body had begun to move in A, or in F, or in G, or in B, provided only that its determination to move, or its velocity, be the fame in all thofe points. Complete the parallelogram BCDE. It is well known, that if one force act on the body which would make it defcribe BC, and another which would make it defcribe BE, the body will defcribe BD. Hence we learn, that when a body has the motion BC changed into the motion BD, it has been acted on in the point B by a force which would have caufed a body at reft in B to defcribe BE. Thus we can difcover the intenfity and direction of the tranfverfe force which produces any deflection from the former direction. In general, the force is that which would have produced in a body at reft that motion BE, which, when compounded with the former motion BC, produces the new motion BD.

Plate VI.

8 Intenfity and direction of deflecting forces.

Thefe two principles, viz. 1ft, that forces are proportional to the velocities which they produce in the fame circumftances, and, 2d, the compofition of motion or forces, will ferve for all the phyfical inveftigations in aftronomy. All the celeftial motions are curvilineal, and therefore are inftances of continual deflection, and of the continual action of tranfverfe or deflecting forces. We muft therefore endeavour to obtain a general meafure of fuch continual deflecting forces.

9 Meafure of thefe forces obtained.

Let two bodies A and *a* (fig. 2.) defcribe in the fame time the arches AC, *a c* of two circles. They are deflected from the tangents AB, *a b*. Let us fuppofe that the direction of the deflecting forces is known to be that of the chords AE, *a e* of thefe circles. Let thefe be called the DEFLECTIVE CHORDS. Draw CB, *c b*, parallel to AE, *a e*, and CD, *c d* parallel to AB, *a b*. Join AC, *a c*, CE, and *c e*. It is plain that the angle BAC is equal to the angle CEA in the alternate fegment. Therefore ACD is alfo equal to it; and, becaufe the angle CAD is common to the two triangles CAD and EAC, thefe two triangles are fimilar, and $AD : AC = AC : AE$, and $AD = \frac{AC^2}{AE}$. For fimilar reafons $a\,d = \frac{a\,c^2}{a\,e}$. But AD and *a d* are refpectively equal to BC and *b c*. Therefore $BC = \frac{AC^2}{AE}$, and $b\,c = \frac{a\,c^2}{a\,e}$. Therefore $BC : b\,c = \frac{AC^2}{AE} : \frac{a\,c^2}{a\,e}$, or $BC : b\,c = AC^2 \times a\,e : a\,c^2 \times AE$. But BC and *b c* being refpectively equal to AD and *a d*, are equal to the fpaces through which the deflecting forces would have impelled the bodies from a ftate of reft in the time of defcribing the arches AC, *a c*. Therefore when thefe times are diminifhed without end, the *ultimate* ratio of AD and *a d* is the ratio of the forces which deflect the bodies in the points A and *a*. But it is evident that the ultimate ratio of AC to *a c* is the ratio of the velocity in the point A to the velocity in the point *a*; becaufe thefe arches are fuppofed to be defcribed in the fame or equal times. Therefore the deflecting forces, by which bodies are made to defcribe arches of circles,

circles, are to each other as the fquares of the velocities directly, and as the deflective cords of thofe circles inverfely. This ratio may be expreffed fymbolically thus, $F:f=\frac{V^2}{C}:\frac{v^2}{c}$; or thus, in a proportional equation, $f \doteq \frac{v^2}{c}$.

It is eafy to fee that in this laft formula f expreffes directly the line $b\ c$, or the fpace through which the body is actually made to deviate from rectilineal motion in the time of defcribing the arch $a\ c$. It is a third proportional to $a\ e$ the deflective chord, and ac the arch of the circumference defcribed in a fmall moment of time. This is the meafure afforded immediately by obfervation. We have obferved the arch AC that is defcribed, and know the direction and the length of AE from fome circumftances of the cafe. The formula which comes to us, when treating this queftion by the help of fluxions, is $f=\frac{2\ v^2}{c}$. This is perhaps a more proper expreffion of the phyfical fact; for it expreffes twice the line $b\ c$, or the meafure of the velocity which the deflecting force would have generated in the body by acting on it during the time of its defcribing the arch $a\ c$. But it is indifferent which meafure we take, provided we always take the fame meafure. The firft mathematicians, however, have committed miftakes by mixing them.

The planets, however, do not defcribe circles: but all the curves which can be defcribed by the action of finite deflecting forces are of fuch a nature, that we can defcribe a circle through any point, having the fame tangent, and the fame curvature which the planetary curve has in that point, and which therefore ultimately coalefces with it. This being the cafe, it is plain that the planet, while paffing through a point of the curve, and defcribing an indefinitely fmall arch of it, is in the fame condition as if defcribing the coincident arch of the equicurve circle. Hence we obtain this moft general propofition, that *the tranfverfe force by which a planet is made to defcribe any curve, is directly as the fquare of its velocity, and inverfely as the deflective chord of the equicurve circle.*

Farther: The velocity of a body in any point A (fig. 2.) of the curve, is equal to that which the deflective force in that point would generate in the body by acting uniformly on it along AF, one-fourth part of the deflective cord AE of the equicurve circle. It is the fame which the body would acquire at F, after a uniformly accelerated motion along AF.

For it is certain that there is fome length AF, fuch that the velocity acquired at F is the fame with the velocity in the point A of the curve. Draw FG parallel to the tangent, and join AG. Make the arch ACI = 2AF. Then, becaufe the fpace defcribed with a uniformly accelerated motion is one half of the fpace which would be uniformly defcribed with the final velocity, the arch ACI would be uniformly defcribed with the velocity which the body has at A in the time that AF is defcribed with the uniformly accelerated motion; and the arch AB will be to the arch AI as the time of defcribing AB to that of defcribing AI; that is, as the time of falling through AD to that of falling through AF. But the motion along AF being uniformly accelerated, the fpaces are as the fquares of the times. Therefore AD is to AF as the fquare of the arch AC to the fquare of the arch AI. But AD is to AF as the fquare of the chord AC is to the fquare of the chord AG. Therefore the arch AC is to the chord AC as the arch AI is to the chord AG. But the arch and chord AC are ultimately in the ratio of equality. Therefore the chord AG is equal to the arch AI. Therefore AG is double of AF. But becaufe the triangles FAG and GAE are fimilar, AF is to AG as AG to AE; and therefore AE is double of AG and quadruple of AF. Therefore the velocity at A in the curve is that which would be produced by the uniform impulfe of the deflecting force along the fourth part of the deflective chord of the equicurve circle.

10 Two ufeful affections of curvilineal motions.

Thefe two affections or properties of curvilineal motions are of the moft extenfive ufe, and give an eafier folution of moft queftions than we obtain by the more ufual methods, and deferve to be kept in remembrance by fuch as engage much in the difcuffion of queftions of this kind.

Thus the inveftigation of the forces which regulate the planetary motions, is reduced to the tafk of difcovering the velocity of the planet in the different points of its orbit, and the curvature in thofe points, and the pofition of the deflective chords.

11 Phyfical fcience of aftronomy

The phyfical fcience of aftronomy muft confift in the difcovery of the general laws which can be affirmed with refpect to the exertion of thofe forces, whether with refpect to their direction or the intenfity of their action. If the mechanician can do more than this, and fhow that every motion that is obferved is an immediate or remote confequence of thofe general laws, he will have completed the fcience, and explained every appearance.

12 Completed by Newton and

This has accordingly been done by Sir Ifaac Newton and his followers. Sir Ifaac Newton has difcovered the general laws which regulate the exertions of thofe forces which produce the planetary motions, by reafoning from general phenomena which had been obferved with a certain precifion before his time; and has alfo fhown that certain confiderable deviations from the generality which he fuppofed to be perfect were neceffary confequences of the very univerfality of the phyfical law, although the phenomenon was not fo general as was at firft imagined. He has gone farther, and has pointed out fome other minute deviations which muft refult from the phyfical law, but which the art of obfervation was not then fufficiently advanced to difcover in the phenomena. This excited the efforts of men of fcience to improve the art of aftronomical obfervation; and not only have the intimations of Newton been verified by modern obfervation, but other deviations have been difcovered, and, in procefs of time, have alfo been fhown to be confequences of the fame general law of agency: And, at this prefent day, there is not a fingle anomaly of the planetary motions which has not been fhown to be a modification of one general law which regulates the action; and therefore characterifes the nature of that fingle force which actuates the whole fyftem of the fun, and his attending planets and comets.

13 His followers.

It was a moft fortunate circumftance that the conftitution of the folar fyftem was fuch that the deviations from the general law are not very confiderable. The cafe might have been far otherwife, although the law, or nature of the planetary force, were the fame, and the

the ſyſtem had been equally harmonious and beautiful. Had two or three of the planets been vaſtly larger than they are, it would have been extremely difficult to diſcover any laws of their motion ſufficiently general to have led to the ſuſpicion or the diſcovery of the univerſal law of action, or the ſpecific circumſtance in the planetary force which diſtinguiſhes it from all others, and characteriſes its nature. But the three laws of the planetary motions diſcovered by Kepler were ſo nearly true, at leaſt with reſpect to the primary planets, that the deviations could not be obſerved, and they were thought to be exact. It was on the ſuppoſition *that they were exact*, that Newton affirmed that they were only modifications of one law ſtill more general, nay univerſal.

We ſhall follow in order the ſteps of this inveſtigation.

14 The ſteps by which they proceeded.

Sir Iſaac Newton took it for granted, that the ſun and planets conſiſted of matter which reſembled thoſe bodies which we daily handle, at leaſt in reſpect of their mobility; and that the forces which agitate them, conſidered merely as moving forces, but without conſidering or attending to their mode of operation, were to be inferred, both as to their direction and as to their intenſity, from the changes of motion which were aſcribed to their agency. He firſt endeavoured to diſcover the *direction* of that tranſverſe force by which the planets are made to deſcribe curve lines. Kepler's firſt law furniſhed him with ample means for this diſcovery. Kepler had diſcovered, that *the right line joining the ſun and any planet deſcribed areas proportional to the times.* Newton demonſtrated, that if a body was ſo carried round a fixed point ſituated in the plane of its motion, that the right line joining it with that point deſcribed areas proportional to the times, the force which deflected it from an uniform rectilineal motion was continually directed to that fixed point. This makes the 2d propoſition of his immortal work *The Mathematical Principles of Natural Philoſophy*, and it is given in the article Astronomy of the Encyclopædia § 260.

Hence Sir Iſaac Newton inferred, that the primary planets were retained in their orbits by a force continually directed to the ſun; and, becauſe Kepler's law of motion was alſo obſerved by the ſecondary planets in their revolutions round their reſpective primary planets, this inference was extended to them.

15 Centripetal forces.

From the circumſtance that the planetary deflecting forces in the different points of the orbit are always directed toward one point as to a centre, they have been called centripetal forces.

16 Velocity of a planet in the different points of its orbit.

From this propoſition may be deduced a corollary which eſtabliſhes a general law of the motion of any planet in the different parts of its orbit, namely, that the velocity which a planet has in the different points of its path are inverſely proportional to the perpendiculars drawn from the ſun on the tangents to the orbit in thoſe points reſpectively. For, let AB, *ab* (fig. 3.) be two arches (extremely ſmall), deſcribed in equal times theſe arches muſt be ultimately proportional to the velocities with which they are deſcribed. Let SP, Sp be perpendicular to the tangents AP, ap. The triangles ASB, aSb are equal, becauſe equal areas are deſcribed by the *radii vectores* SA, Sa, in equal times: but in equal triangles, the baſes, AB, ab, are reciprocally as their heights SP, Sp, or AB : ab = Sp : SP.

This corollary gives us another expreſſion of the ratio of the centripetal forces in different points A and a of a curve. We ſaw by a former propoſition, that the force at A (fig. 2.) is to the force at a as $AC^2 \times ae$ to $ac^2 \times AE$, which we may expreſs thus: $F : f = V^2 \times c : v^2 \times C$. If we expreſs the perpendiculars SP, Sp (in fig. 3.) by the ſymbols P, p, we have $V^2 : v^2 = p^2 : P^2$, and therefore $F : f = p^2 \times c : P^2 \times C$. *The centripetal forces in different points of an orbit are in the ratio compounded of the inverſe duplicate ratio of the perpendiculars drawn to the tangents in thoſe points from the centre of forces, and the inverſe ratio of the deflective chords of the equicurve circles.* 17

Law of action of the centripetal force.

We are now in a condition to determine the law of action of the centripetal force by which a planet is retained in its orbit round the ſun, or the relation which ſubſiſts between the intenſity of its action and the diſtance of the planet from the ſun: for we know the elliptical figure of the orbit, and we can draw a tangent to it in any point, and a perpendicular from the ſun to that tangent.

Kepler's ſecond law or obſervation of the planetary motions was, that *each primary planet deſcribed an ellipſe, having the ſun in one focus.* It is eaſy to ſhow, even without any knowledge of the geometrical properties of the ellipſe, what is the proportion of the intenſities of the deflecting force at the aphelion and perihelion (ſee fig. 4.) At thoſe two points of the orbit, the motion of the planet is at right angles to the line joining it with the ſun. Therefore, ſince the areas deſcribed in equal times are equal, the arches deſcribed in equal times muſt be inverſely as the diſtances from the ſun; or the velocities muſt be inverſely as the diſtances from the ſun. But the curvature in the aphelion and perihelion is the ſame; and therefore the diameters of the equicurve circles in thoſe points are equal. But thoſe diameters are, in this particular caſe, what we called the deflective chords. Therefore, calling the aphelion and perihelion diſtances D and d, the velocities in the aphelion and perihelion V and v, let the common deflective chord be C. Then we have $F : f = V^2 \times C : v^2 \times C, = V^2 : v^2, = d^2 : D^2$. That is, the forces which deflect the planet in the aphelion and perihelion are inverſely as the ſquares of the diſtances from the ſun. A perſon almoſt ignorant of mathematics may ſee the truth of this by looking into a table of natural verſed ſines. He will obſerve, that the verſed ſine of one degree is quadruple the verſed ſine of half a degree, and ſixteen times the verſed ſine of a quarter of a degree; in ſhort, that the verſed ſines of ſmall arches are in the proportion of the ſquares of the arches. Now ſince the arches deſcribed in equal times are inverſely as the diſtances, their verſed ſines are inverſely as the ſquares of the diſtances. But theſe verſed ſines are the ſpaces through which the centripetal forces at the aphelion and perihelion deflect the planet from the tangent. Therefore, &c.

Thus we have found, that in the aphelion and perihelion the centripetal force acts with an intenſity that is proportional to the ſquares of the diſtances inverſely. As theſe are the extreme ſituations of a planet, and as the

the proportion of the aphelion and perihelion diſtances are conſiderably different in the different planets, and yet this law of action is obſerved in them all, it is reaſonable to imagine that it holds true, not in thoſe ſituations only, but in every intermediate ſituation. But a conjecture, however probable, is not ſufficient, when we aim at accurate ſcience, and it is neceſſary to examine whether this law of action is really obſerved in every point of the elliptical orbit.

18 Demonſtrated with reſpect to the earth,

For this purpoſe it is neceſſary to mention ſome geometrical properties of the ellipſe. Therefore let ADBE (fig. 4.) be the elliptical orbit of a planet or comet, having the ſun in the focus S. Let AB be the tranſverſe axis, and DE the conjugate axis, and C the centre. Let P be any point of the ellipſe. Draw PS through the focus. Draw the tangent PN, and SN from the focus, perpendicular to PN. Draw PQ perpendicular to PN, meeting the tranſverſe axis in Q. Draw QO parallel to PN, meeting PS in O. Alſo draw QR perpendicular to PS. Biſect PO in T.

It is demonſtrated in the treatiſes of conic ſections, that PO is one half of the chord of the equicurve or oſculating circle drawn through the point P. Therefore PO is one half of the deflective chord of the planetary orbit. It is alſo demonſtrated, that PR is one half of the parameter or *latus rectum* of the tranſverſe axis AB, or that it is the third proportional to AC and DC. Therefore PR or D r is of the ſame conſtant magnitude, in whatever part of the circumference the point P is taken.

It is evident that the triangles NSP, RPQ, and QPO, are all ſimilar, by reaſon of the parallels PN, QO, and the right angles SNP, PRQ, PQO. Therefore we have PR : PQ = PQ : PO. Therefore PR : PO = PR² : PQ², = SN² : SP². Therefore PR × SP² = PO × SN². But the *latus rectum* L is equal to twice PR, and the deflective chord C is equal to twice PO. Therefore L × SP² = C × SN². But we have ſeen, that when a curve is deſcribed by means of a centripetal force, ſo that areas are deſcribed proportional to the times, and therefore the velocities are reciprocally proportional to the perpendiculars drawn from the centre of forces to the tangents, the forces are inverſely proportional to C × SN². Therefore, in the elliptical motion of the planets, the forces are inverſely proportional to L × SP²; and ſince L is a conſtant quantity, the centripetal forces are inverſely proportional to SP², or to the ſquares of the diſtances from the ſun.

Thus it appears that, with reſpect to any individual planet, the centripetal force which continually deflects it from the tangent to its orbit diminiſhes in the inverſe

19 Obſerved in the motion of the moon &c.

duplicate ratio of the diſtance from the ſun. The ſame thing is obſerved to be very nearly true in the moon's motion round the earth, and in the motion of ſuch ſatellites of Jupiter and Saturn as deſcribe orbits which are ſenſibly elliptical. It is alſo obſerved in the motion of the comets, at leaſt in that which appeared in 1682 and in 1759.

It was therefore very natural for Sir Iſaac Newton to examine whether the like diminution of force obtained in the action of this force on different planets; that is, whether the deflection of the earth from the tangent of its orbit was to the ſimultaneous deflection of Jupiter as the ſquare of Jupiter's diſtance from the ſun to the ſquare of the earth's diſtance. This was very probable, but by no means certain. Its probability is very great indeed, when we know that a comet moves ſo in its orbit that its deflections in equal times are inverſely as the ſquares of its diſtances from the ſun, and that the comet paſſes through the orbits of all the planets; and when at the ſame diſtance from the ſun as any one of them, it ſuffers the ſame deflection with it. Newton therefore calculated the actual ſimultaneous deflections of the different planets, and found them agreeable to this law. But it was deſirable to obtain a demonſtration of this important propoſition in general terms. This was ſupplied by Kepler's third general obſervation of the motions, viz. that *the ſquares of the periodic times of the different planets were proportional to the cubes of their mean diſtances from the ſun.* The orbits of the planets are ſo nearly circular, that we may ſuppoſe them exactly ſo in the preſent queſtion, without any remarkable error. In this caſe, then, the deflective chords are the diameters of the orbits (for DS is equal to AC), and are proportional to the diſtances, which are their halves. The centripetal forces, being proportional to $\frac{v^2}{c}$, are proportional to $\frac{v^2}{d}$, when d is the radius of the orbit, or the mean diſtance from the ſun. But the velocity in a circular orbit is as the circumference directly, and as the time of a revolution inverſely. Therefore, inſtead of v^2, we may write $\frac{d^2}{t^2}$, and then the forces will be proportional to $\frac{d^2}{t^2\,d}$, or to $\frac{d}{t^2}$; that is, directly as the diſtances, and inverſely as the ſquares of the times of revolution. But, by Kepler's obſervation, t^2 is proportional to d^3. Therefore the centripetal forces are proportional to $\frac{d}{d^3}$, or to $\frac{1}{d^2}$; that is, inverſely as the ſquares of the mean diſtances from the ſun.

20 And demonſtrated in general terms.

But ſince the orbits of the planets are not accurate circles, this determination is but an approximation to the truth, and therefore inſufficient for the foundation of ſo important a propoſition; at any rate, it will not apply to the comets, whoſe orbits are very far from being circular. We muſt obtain a more accurate demonſtration.

Therefore draw SD (fig. 4.) to the extremity of the conjugate axis, and biſect it in t. About S, with the radius SD, deſcribe the circle DFG. Let D d, D δ be equal ſmall arches of the ellipſe and the circle. Join dS, δS. It is well known that DS is half of the chord of the equicurve circle at D, and therefore D t is one fourth part of it. It has been demonſtrated, that the velocity in any point D of a curve, deſcribed by means of a deflecting force, is that which the force in that point would communicate to it by uniformly impelling it along the fourth part of the deflective chord, that is, along D t. But if a body revolved round S in a circle DFG, its velocity in that circle would be that which the deflecting force would communicate to it by uniformly impelling it along one-fourth of the diameter, that is, along D t. Therefore the planet, if projected in the direction D δ, with the velocity which it has in the point D of the ellipſe, would deſcribe the circle DFG by the action of the centripetal force. Farther, it would deſcribe it in the ſame time that it deſcribes the ellipſe; for becauſe the velocities are equal, the areas

D S d,

D S d, D S δ are described in the same time. But the bases D d, D δ being equal, these areas are as their heights S n (or CD), and SD (or CA). But because the diameter of the circle is equal to AB, the area of the whole ellipse is to the area of the circle as CD is to CA; that is, as the area D S d to the area D S δ described in the same time. Therefore the elliptical and circular areas are similar portions of the ellipse and circle; and therefore the times of describing them are similar portions of the whole revolutions in the ellipse and in the circle. Therefore these revolutions are performed in equal times.

And thus it follows, that if all the planets and comets were projected, when at their mean distances from the sun, perpendicularly to the *radii vectores*, they would describe circles round the sun, and the squares of their periodic times would be proportional to the cubes of their mean distances from the sun, as Kepler has observed; and therefore the centripetal forces would be inversely as the squares of their distances from the sun.

21 All the planets retained in their respective orbits by one and the same force.

They are not different forces therefore which retain the different planets in their respective orbits, but one force, acting by the same law upon them all. We may either conceive it as an attractive force, exerted by the sun, or as a tendency in each planet; nay, nothing hinders us from conceiving it as a force external, both to sun and planets, impelling them towards the sun. It may be the impulse of a stream of fluid moving continually toward the sun. Sir Isaac Newton did not concern himself with this question, but contented himself with the discovery of the law according to which its action was exerted. The steps of this investigation showed him, that a body, projected in any direction whatever, and with any velocity whatever, and subjected to the action of a force directed to the sun, and inversely proportional to the square of the distance from the sun, will necessarily describe a conic section, having the sun in the focus. This will be a parabola, if the velocity of projection be that which the centripetal force in that place would communicate to the body by acting on it uniformly along a line equal to half its distance from the sun. If the velocity be greater than this, the path will be a hyperbola; if the velocity be less than this, the path will be an elliptical orbit, in which the body will revolve for ever round the sun.

The 3d Keplerean law is also observed in the revolutions of the satellites of Jupiter, Saturn, and the lately discovered planet; and we must infer from it, that they are retained in their orbits round their respective primary planets, by forces whose intensity decreases according to the same law of the distances. Also the elliptical motion of the moon round the earth, shows that the force by which she is retained in her orbit varies in the same proportion of the distances. But when we compare the motion of a satellite of Jupiter with that of one of the satellites of the other two planets, we find that the proportion does not hold. We shall find, that, at equal distances from Jupiter and Saturn, the force toward Jupiter is almost thrice as great as the force toward Saturn. We shall also find that the force toward Jupiter is three hundred times greater than the force which retains the moon in its elliptical orbit round the earth, when acting at the same distance.

Since a force directed to the sun, and inversely as the square of the distance, is thus found to pervade all the planetary orbits, it is highly improbable that it will not affect the secondary planets also. The moon accompanies the earth in its motion round the sun. It may appear sufficient for this purpose, that the moon be retained in its orbit by a force directed to the earth. Were the moon connected with the earth by a rope or chain, this would be true; for the earth could get no motion without dragging the moon along with it: but it is quite otherwise with bodies moving in free space, without any material connections. When a body that is moving uniformly in a straight line is accompanied by another which describes around it areas proportional to the times, the force which continually deflects this satellite is always directed to the moving central body.

22 The satellites of all the planets subjected to this solar action.

This is easily seen; for whatever be the mutual action of two bodies, and their relative motions in consequence of this action, if the same velocity be impressed at once on both bodies in the same direction, their mutual actions and relative motions will be the same as they would have been without this common impulse. Thus every thing is done in a ship that is sailing steadily in the same manner as if she were at rest. If therefore the moon be observed to describe areas round the earth, which are *precisely* proportional to the times, while the earth moves in an orbit round the sun, we must infer that the moon receives, in every instant, an impulse the same in every respect with what the earth receives at the same instant; or that the moon is acted on by a force parallel to the earth's distance from the sun, and proportional to the square of that distance inversely. Now this is very nearly true of the lunar motions; and we must infer that the moon is subjected to this solar action, or this tendency to the sun. The same must be affirmed of the satellites of the other planets.

But a force inversely proportional to the square of the earth's distance from the sun is not what the universality of the law requires: It must be inversely as the square of the moon's distance from the sun: and it must not be parallel to the earth's distance from the sun, but must be directed toward the sun; and therefore, in the quadratures, it must converge to the earth's *radius vector*. Therefore, since a force having the above mentioned conditions will allow the description of areas round the earth exactly proportional to the times, a force acting on the moon, inversely proportional to the square of her distance from the sun, and directed exactly to the sun, is incompatible with the accurate elliptical motion round the earth.

23 How the irregularity of the moon's motion

At new moon, her tendency to the sun exceeds the earth's tendency to him, and this excess will diminish her tendency to the earth, and her motion will be less incurvated, so that she will retire a little from the earth. At full moon, the earth's tendency to the sun exceeds the moon's tendency to him, and the earth will separate a little from the moon, so that the relative orbit will again be less incurvated. In the quadratures, the impulse on the moon is indeed equal to that on the earth, but not parallel, and tends to make the moon approach the earth, and increase the curvature of her orbit. In other situations of the moon, this want of equality and parallelism of the forces acting on the earth and moon, must produce other disturbances of the regular elliptical motion.

Newton ſaw this at once; and, to his great delight, he ſaw that the great deviations from regular motion, which had been diſcovered by Ptolemy and Tycho Brahé called the *Annual Equation*, the *Variation*, and the *Evection*, were ſuch as moſt obviouſly reſulted from the regular influence of the ſun on the moon. The firſt deviation from the regular elliptical motion is occaſioned by the increaſe of the ſun's diſturbing force as the earth approaches the perihelion; and it enlarges the lunar orbit, by diminiſhing the tendency to the earth, and increaſes the periodic time. The ſecond ariſes from the *direction* of the diſturbing force, by which it accelerates the moon's angular motion in the ſecond and fourth quadrants of her orbit, and retards it in the firſt and third. The laſt affects the eccentricity of the orbit, by changing the ratio of the whole or compound tendency of the moon to the earth in her perigee and apogee.

24 May be calculated with preciſion.

This ſucceſs incited him to an accurate examination of the conſequences of this influence. It is the boaſt of this diſcovery of the law of the planetary deflections that all its effects may be calculated with the utmoſt preciſion. The part of the moon's deflection toward the ſun, which is neither equal nor parallel to the ſimultaneous deflection of the earth, may be ſeparated from the part which is equal and parallel to it, and it may be called the ſun's diſturbing force. Its proportion to the moon's deflection towards the earth may be accurately aſcertained, and its inclination to the line of the moon's motion in every point of her orbit may be pointed out. This being done, the accumulated effect of this diſturbing force after any given time, however variable, both in direction and intenſity during this time, may be determined by the 39th and other propoſitions of the firſt book of the Mathematical Principles of Natural Philoſophy. And thus may the moon's motion, when ſo diſturbed, be determined and compared with her motion really obſerved.

All this has been done by Sir Iſaac Newton with the moſt aſtoniſhing addreſs and ſagacity, *ſua matheſi facem preferente*, partly in the Principia, and partly in his Lunæ Theoria. This inveſtigation, whether we conſider the complete originality of the whole proceſs, or the ingenuity of the method, or the ſagacity in ſeeing and clearly diſcriminating the different circumſtances of the queſtion, or the wonderful fertility of reſource, or the new and moſt refined mathematical principles and methods that he employed—muſt ever be conſidered as the moſt brilliant ſpecimen of human invention and reaſoning that ever was exhibited to the world.

In this inveſtigation Newton not only determined the quantity, the period, and the changes of thoſe inequalities, which had been ſo conſiderable and remarkable as to be obſerved by former aſtronomers, and this with an exactneſs far ſurpaſſing what could ever be attained by mere obſervation; but he alſo pointed out ſeveral other periodical inequalities, which were too ſmall, and too much implicated with the reſt, ever to be diſcovered or to be ſeparated from them. We do not ſay that he completed the theory of the lunar motions; but he pointed out the methods of inveſtigation, and he furniſhed all the means of proſecuting it, by giving the world the elements of a new ſpecies of mathematics, without which it would have been in vain to attempt it. Both this new mathematics, and the methods of applying it to ſuch queſtions, have been aſſiduouſly ſtudied and improved by the great mathematicians of this century; and the lunar theory has been carried to ſuch a degree of perfection, that we can compute her place in the heavens for any paſt age without deviating above one minute of a degree from the actual obſervation.

25 The ſecular equation of the moon's mean diſtance

There is one empirical equation of the moon's motion which the compariſon of ancient and modern eclipſes obliges the aſtronomers to employ, without being able to deduce it, like the reſt, *à priori*, from the theory of an univerſal force inverſely proportional to the ſquare of the diſtance. It has therefore been conſidered as a ſtumbling block in the Newtonian philoſophy. This is what is called *the ſecular equation of the moon's mean motion*. The mean motion is deduced from a compariſon of diſtant obſervations. The time between them, being divided by the number of intervening revolutions, gives the average time of one revolution, or the mean lunar period. When the ancient Chaldean obſervations are compared with thoſe of Hipparchus, we obtain a certain period; when thoſe of Hipparchus are compared with ſome in the 9th century, we obtain a period ſomewhat ſhorter; when the laſt are compared with thoſe of Tycho Brahé, we obtain one ſtill ſhorter; and when Brahé's are compared with thoſe of our day, we obtain the ſhorteſt period of all—and thus the moon's mean motion appears to accelerate continually; and the accelerations appear to be in the duplicate ratio of the times. The acceleration for the century which ended in 1700 is about 9 ſeconds of a degree; that is to ſay, the whole motion of the moon during the 17th century muſt be increaſed 9 ſeconds, in order to obtain its motion during the 18th; and as much muſt be taken from it, or added to the computed longitude, to obtain its motion during the 16th; and the double of this muſt be taken from the motion during the 16th, to obtain its motion during the 15th, &c. Or it will be ſufficient to calculate the moon's mean longitude for any time paſt or to come by the ſecular motion which obtains in the preſent century, and then to add to this longitude the product of 9 ſeconds, multiplied by the ſquare of the number of centuries which intervene. Thus having found the mean longitude for the year 1200, add 9 ſeconds, multiplied by 36, for ſix centuries. By this method we ſhall make our calculation agree with the moſt ancient and all intermediate obſervations. If we neglect this correction, we ſhall differ more than a degree from the Chaldean obſervations of the moon's place in the heavens.

The mathematicians having ſucceeded ſo completely in deducing all the obſerved inequalities of the planetary motions, from the ſingle principle, that the deflecting forces diminiſhed in the inverſe duplicate ratio of the diſtances, were fretted by this exception, the reality of which they could not conteſt. Many opinions were formed about its cauſe. Some have attempted to deduce it from the action of the planets on the moon; others have deduced it from the oblate form of the earth, and the tranſlation of the ocean by the tides; others have ſuppoſed it owing to the reſiſtance of the ether in the celeſtial ſpaces; and others have imagined that the action of the deflecting force requires time for its propagation to a diſtance: But their deductions have been proved unſatisfactory, and have by no means the preciſion and evidence that have been attained in the other queſtions of phyſical aſtronomy. At laſt M. de la la Place, of the Royal Academy of Sciences at Paris, has happily ſucceeded, and deduced the ſecular equation of the moon from the Newtonian law of planetary deflection. It is produced in the following manner.

26
Deduced from the Newtonian law of planetary deflection.

Suppoſe the moon revolving round the earth, undiſturbed by any deflection toward the ſun, and that the time of her revolution is exactly aſcertained. Now let the influence of the ſun be added. This diminiſhes her tendency to the earth in oppoſition and conjunction, and increaſes it in the quadratures: but the diminutions exceed the augmentations both in quantity and duration; and the exceſs is equivalent to $\frac{1}{179}$th of her tendency to the earth. Therefore this diminiſhed tendency cannot retain the moon in the ſame orbit; ſhe muſt retire farther from the earth, and deſcribe an orbit which is leſs incurvated by $\frac{1}{179}$th part; and ſhe muſt employ a longer time in a revolution. The period therefore which we obſerve, is not that which would have obtained had the moon been influenced by the earth alone. We ſhould not have known that her natural period was increaſed, had the diſturbing influence of the ſun remained unchanged; but this varies in the inverſe triplicate ratio of the earth's diſtance from the ſun, and is therefore greater in our winter, when the earth is nearer to the ſun. This is the ſource of the annual equation, by which the lunar period in January is made to exceed that in July nearly 24 minutes. The angular velocity of the moon is diminiſhed in general $\frac{1}{179}$, and this numerical coefficient varies in the inverſe ratio of the cube of the earth's diſtance from the ſun. If we expand this inverſe cube of the earth's diſtance into a ſeries arranged according to the ſines and coſines of the earth's mean motion, making the earth's mean diſtance unity, we ſhall find that the ſeries contains a term equal to $\frac{3}{2}$ of the ſquare of the eccentricity of the earth's orbit. Therefore the expreſſion of the diminution of the moon's angular velocity contains a term equal to $\frac{1}{179}$ of this velocity, multiplied by $\frac{3}{2}$ of the ſquare of the earth's eccentricity; or equal to the product of the ſquare of the eccentricity, multiplied by the moon's angular velocity, and divided by 119,33. ($\frac{2}{3}$ of 179). Did this eccentricity remain conſtant, this product would alſo be conſtant, and would ſtill be confounded with the general diminution, making a conſtant part of it: but the eccentricity of the earth's orbit is known to diminiſh, and its diminution is the reſult of the univerſality of the Newtonian law of the planetary deflections. Although this diminution is exceedingly ſmall, its effect on the lunar motion becomes ſenſible by accumulation in the courſe of ages. The eccentricity diminiſhing, the diminution of the moon's angular motion muſt alſo diminiſh, that is, the angular motion muſt increaſe.

During the 18th century, the ſquare of the earth's eccentricity has diminiſhed 0,000015325, the mean diſtance from the ſun being = 1. This has increaſed the angular motion of the moon in that time 0,00000001285. As this augmentation is gradual, we muſt multiply the angular motion during the century by the half of this quantity, in order to obtain its accumulated effect. This will be found to be 9″ very nearly, which exceeds that deduced, from a moſt careful compariſon of the motion of the laſt two centuries, only by a fraction of a ſecond!

As long as the diminution of the ſquare of the eccentricity of the earth's orbit can be ſuppoſed proportional to the time, this effect will be as the ſquares of the times. When this theory is compared with obſervations, the coincidence is wonderful indeed. The effect on the moon's motion is periodical, as the change of the ſolar eccentricity is, and its period includes millions of years. Its effect on the moon's longitude will amount to ſeveral degrees before the ſecular acceleration change to a retardation.

Thoſe who are not familiar with the diſquiſitions of modern analyſis, may conceive this queſtion in the following manner.

Let the length of a lunar period be computed for the earth's diſtance from the ſun for every day of the year. Add them into one ſum, and divide this by their number, the quotient will be the mean lunar period. This will be found to be greater than the arithmetical medium between the greateſt and the leaſt. Then ſuppoſe the eccentricity of the earth's orbit to be greater, and make the ſame computation. The average period will be found ſtill greater, while the medium between the greateſt and leaſt periods will hardly differ from the former. Something very like this may be obſerved without any calculation, in a caſe very ſimilar. The angular velocity of the ſun is inverſely as the ſquare of his diſtance. Look into the ſolar tables, and the greateſt diurnal motion will be found 3673″, and the leaſt 3433″. The mean of theſe is 3553″, but the medium of the whole is 3548″. Now make a ſimilar obſervation in tables of the motion of the planet Mars, whoſe eccentricity is much greater. We ſhall find that the medium between the greateſt and leaſt exceeds the true medium of all in a much greater proportion.

27
Certainty and utility of this law.

Thus has the patient and aſſiduous cultivation of the Newtonian diſcoveries explained every phenomenon, and enabled us to foreſee changes in them which no examination of the paſt appearances, unaſſiſted by this theory, could have pointed out, and which muſt have exceedingly embarraſſed future aſtronomers. This great but ſimple law of deflection repreſents every phenomenon of the ſyſtem in the moſt minute circumſtances. Far from fearing that future experience may overturn this law, we may reſt aſſured that it will only confirm it more and more; and we may confide in its moſt remote conſequences as if they were actually obſerved.

28
Reciprocal deflection of the earth and moon, and of the ſun and planets,

It is diſcovered by obſervation, that the deflection of the moon to the earth, and of the planets to the ſun, are accompanied by an equal and oppoſite deflection of the earth to the moon, and of the ſun to the planets.

The tendency of the earth to the moon is plainly indicated by the riſe of the waters of the ocean under the moon, and on the oppoſite ſide of the earth. Sir Iſaac Newton tried what ſhould be the reſult of a tendency of the water to the moon. His inveſtigation of this queſtion was very ſimilar to that in his lunar theory. We may conceive the moon to be one of many millions of particles of a fluid, occupying a globe as big as the lunar orbit. Each will feel a ſimilar diſturbing force, which will diminiſh its tendency to the earth in the neighbourhood of the place of conjunction and oppoſition, and will increaſe it in the neighbourhood of the quadratures. They cannot therefore remain in equilibrio in their ſpherical form; they muſt ſink in the quadratures, and riſe in the conjunction and oppoſition, till their greater height compenſates for the diminiſhed weight of each particle. In like manner, the waters of the ocean

29
Proved by the ebbing and flowing of the ſea,

ocean muſt ſink on thoſe parts of the earth where the moon is ſeen in the horizon, and muſt riſe in thoſe which have the moon in the zenith or nadir. All theſe effects are not only to be ſeen in general, but they may all be calculated, and the very form pointed out which the ſurface of the ocean muſt aſſume: and thus a tendency of every particle of the ocean to the moon, inverſely proportional to the ſquare of its diſtance from it, gives us a theory of the ebbing and flowing of the ſea. This is delivered in ſufficient detail in the article TIDE of the Encyclopædia, and therefore need not be inſiſted on in this place. The ſame inference muſt be drawn from the preceſſion of the equinoxes produced by the action of the moon on the protuberant matter of our equatoreal regions. See PRECESSION in the Encycl.

30 And by different computations of the ſun's place in the heavens.

But the mutual tendency of the earth and moon is clearly ſeen in a phenomenon that is much more ſimple. If we compute the ſun's place in the heavens, on the ſuppoſition that the earth deſcribes areas proportional to the times, we ſhall find it to agree with obſervation at every new and full moon: But at the firſt quarter the ſun will be obſerved about 9 ſeconds too much advanced to the eaſtward; and at the laſt quarter he will be as much to the weſtward of his calculated place. In all intermediate poſitions, the deviation of the obſerved from the computed place of the ſun will be 9 ſeconds, multiplied by the ſine of the moon's diſtance from conjunction or oppoſition. In ſhort, the appearances will be the ſame as if it were not the earth which deſcribed areas proportional to the times round the ſun, but that a point, lying between the earth and moon, and very near the earth's ſurface, were deſcribing the ellipſe round the ſun, while the earth and moon revolve round this point in the courſe of a lunation, having the point always in the line between them, in the ſame manner as if they were on the extremities of a rod which turns round this point, while the point itſelf revolves round the ſun.

This then is the fact with reſpect to the motions; and the earth in a month deſcribes an orbit round this common centre of the earth and moon. It cannot do this unleſs it be continually deflected from the tangent to this orbit: therefore it is continually deflected toward the moon: and the momentum of this deflection, that is, its quantity of motion, is the ſame with that of the moon's deflection, becauſe their diſtances from the common centre are as their quantities of matter inverſely.

Appearances perfectly ſimilar to theſe oblige us to affirm that the ſun is continually deflected toward the planets. Aſtronomical inſtruments, and the art of obſerving, have been prodigiouſly improved ſince Sir Iſaac Newton's time; and the moſt ſcrupulous attention has been paid to the ſun's motion, becauſe it is to his place in the univerſe that continual reference is made in computing the place of all the planets. He is ſuppoſed at reſt in the common focus of all their orbits; and the *obſerved* diſtance of a planet from the ſun is always conſidered as the *radius vector*. If this be not the caſe, the orbital motions contained in our tables are not the abſolute motions of the planets, nor the deflections from the tangents the real deflections from abſolute rectilineal motion; and therefore the forces are not ſuch as we infer from thoſe miſtaken deflections. Accordingly Sir Iſaac Newton, induced by certain metaphyſical conſiderations, aſſumed it as a law of motion, that every action of a body A on another body B, is accompanied by an equal and contrary action of B on A. We do not ſee the propriety of this aſſertion as a metaphyſical axiom. It is perfectly conceivable that a piece of iron will always approach a magnet when in its neighbourhood; but we do not ſee that this obliges us to aſſert that *therefore* the magnet will alſo approach the iron. Thoſe who explain the phenomena of magnetiſm by the impulſe of a fluid, muſt certainly grant that there is no metaphyſical neceſſity for another ſtream of fluid impelling the magnet toward the iron. And accordingly this, and the ſimilar reciprocity in the phenomena of electricity, have *always* been conſidered as deductions of experimental philoſophy; yet we obſerve the ſame reciprocity in all the actions of ſublunary bodies; and Newton's third law of motion is received as true, and admitted as a principle of reaſoning. But we apprehend that it was haſty in this great philoſopher, and unlike his ſcrupulous caution, to extend it to the planetary motions. He did, however, extend it, and aſſerted, that as each planet was deflected toward the ſun, the ſun was equally (in reſpect of momentum) deflected toward each planet, and that his real motion was the compoſition of all thoſe ſimultaneous deflections. He aſſerted, that there was a certain point round which the ſun and his attending planets revolved; and that the orbit of a planet, which our meaſurements determined by continual reference to the ſun as to a fixed body, was not the true orbit, but conſiſted of the contemporaneous orbits of that planet and of the ſun round this fixed point. Any little ſector of the apparent orbit was greater than the correſponding ſector of the planet's true orbit in abſolute ſpace, and the apparent motion was compounded of the true motion of the planet, and the oppoſite to the true motion of the ſun. After a moſt ingenious and refined inveſtigation, he ſhowed that, notwithſtanding this great difference of the Keplerean laws from the truth, the inference, with reſpect to the law of planetary deflection, is juſt, and that not only the apparent deflections are in the inverſe duplicate ratio of the diſtances from the ſun, but that the real deflections vary in the ſame ratio of the diſtances from the fixed point, and alſo from the ſun; for he ſhewed that the diſtances from the ſun were in a conſtant ratio to the diſtances from this point. He ſhewed alſo that the ſame forces which produced the contemporaneous revolution of a planet and the ſun round the centre of the ſyſtem, would produce a revolution of the planet in a ſimilar orbit round the ſun (ſuppoſed to be held faſt in his place) at the ſame diſtance which really obtains between them, with this ſole difference, that the periodic time will be longer, in the ſubduplicate ratio of the quantity of matter in the ſun to the quantity of matter of the ſun and planet together. Areas will be deſcribed proportional to the times, and the orbit will be elliptical; but the ratio of the ſquares of the periodic times will not be the ſame with the ratio of the cubes of the diſtances, unleſs all the planets are equal.

31 Obſervations on the third law of motion.

32 Newton's extenſion of that law

Thus was the attention of aſtronomers directed to a number of *apparent* irregularities in the motion of the earth, which muſt reſult from this derangement of the ſun, which they had imagined to remain ſtedfaſt in his place.

place. They were told what to expect, and on what positions of the planets the kind and quantity of every irregularity depended. This was a most inviting field of observation to a curious speculatist; but it required the nicest and most expensive instruments, and an uninterrupted series of long continued observations, sufficient to occupy the whole of a man's time. Fortunately the accurate determination of the solar and lunar motions were of the utmost importance, nay, indispensably necessary for solving the famous problem of the longitude of a ship at sea: and thus the demands of commercial Europe came in aid of philosophical curiosity, and occasioned the erection of observatories, first at Greenwich, and soon after at Paris and other places, with establishments for astronomers, who should carefully watch the motions of the sun and moon, not neglecting the other planets.

33
Confirmed by observation.

The fortunate result of all this solicitude has been the complete establishment of the Newtonian conjecture (for so we must still think it), and the verification of Newton's assertion, that action was accompanied, through the whole solar system, by an equal and contrary reaction. All the inequalities of the solar motion predicted by Newton have been observed, although they are frequently so complicated that they could never have been detected, had not the Newtonian theory directed us when to find any of them pretty clear of complication, and how to ascertain the accumulated result of them all in any state of combination.

But in the course of this attention to the motions of the sun and moon, the planets came in for a share, and considerable deviations were found, from the supposition that all their deflections were directed to the sun, and were in the inverse duplicate ratio of their distances. The nice observation shewed, that the period of Jupiter was somewhat shorter than Kepler's law required.

A slight reflection shewed that this was no inconsistency; because the common centre of the conjoined orbits of the Sun and Jupiter was sensibly distant from the centre of the sun, namely, about the 1100th part of the *radius vector*; and therefore the real deflection was about a 2200th part less than was supposed. It was now plain that the distances to which the Keplerean law must be applied, are the distances, not from the sun, but from the fixed point round which the sun and planets revolve. This difference was too small to be observed in Kepler's time; but the seeming error is only a confirmation of the Newtonian philosophy.

But there are other irregularities which cannot be explained in this manner. The planetary orbits change their position; their aphelia advance, their nodes recede, their inclination to each other vary. The mean motions of Saturn and Jupiter are subject to considerable changes, which are periodical.

34
Deflection of the planets towards each other.

Sir Isaac Newton had no sooner discovered the universality and reciprocity of the deflections of the planets and the sun, than he also suspected that they were continually deflected towards each other. He immediately obtained a general notion of what should be the more general results of such a mutual action. They may be conceived in this way.

Plate VI.

Let S (fig. 5.) represent the sun, E the earth, and I Jupiter, describing concentric orbits round the centre of the system. Make $IS : EA = EI^2 : SI^2$. Then, if IS be taken to represent the deflection of the sun toward Jupiter, EA will represent the deflection of the Earth to Jupiter. Draw EB equal and parallel to SI, and complete the parallelogram EBAD. ED will represent the disturbing force of Jupiter. It may be resolved into EF, perpendicular to ES, and EG in the direction of SE. By the first of these the earth's angular motion round the sun is affected, and by the second its deflection toward him is diminished or increased.

35
General result of such mutual action.

In consequence of this first part of the disturbing force, the angular motion is increased, while the earth approaches from quadrature to conjunction with Jupiter (which is the case represented in the figure), and is diminished from the time that Jupiter is in opposition till the earth is again in quadrature, westward of his opposition. The earth is then accelerated till Jupiter is in conjunction with the sun; after which it is retarded till the earth is again in quadrature.

The earth's tendency to the sun is diminished while Jupiter is in the neighbourhood of his opposition or conjunction, and increased while he is in the neighbourhood of his stationary positions. Jupiter being about 1000 times less than the sun, and 5 times more remote, IS must be considered as representing $\frac{1}{25000}$th of the earth's deflection to the sun, and the forces ED and EG are to be measured on this scale.

In consequence of this change in the earth's tendency to the sun, the aphelion sometimes advances by the diminution, and sometimes retreats by the augmentation. It advances when Jupiter chances to be in opposition when the earth is in its aphelion; because this diminution of its deflection towards the sun makes it later before its path is brought from forming an obtuse angle with the *radius vector*, to form a right angle with it. Because the earth's tendency to the sun is, on the whole, more diminished by the disturbing force of Jupiter than it is increased, the aphelion of the earth's orbit advances on the whole.

In like manner the aphelia of the inferior planets advance by the disturbing forces of the superior: but the aphelion of a superior planet retreats; for these reasons, and because Jupiter and Saturn are larger and more powerful than the inferior planets, the aphelia of them all advance while that of Saturn retreats.

In consequence of the same disturbing forces, the node of the disturbed planet retreats on the orbit of the disturbing planet; therefore they all retreat on the ecliptic, except that of Jupiter, which advances by retreating on the orbit of Saturn, from which it suffers the greatest disturbance. This is owing to the particular position of the nodes and the inclinations of the orbits.

The inclination of a planetary orbit increases while the planet approaches the node, and diminishes while the planet retires from it. 36

A peculiarity explained in the motions of Jupiter and Saturn.

M. de la Place has completed this deduction of the planetary inequalities, by explaining a peculiarity in the motions of Jupiter and Saturn, which has long employed the attention of astronomers. The accelerations and retardations of the planetary motions depend, as has been shown, on their configurations, or the relative quarters of the heavens in which they are. Those of Mercury, Venus, the Earth, and Mars, arising from their mutual deflections; and their more remarkable deflections to the great planets Jupiter and Saturn, nearly compensate each other, and no traces of them remain after a few revolutions: but the positions of the aphelia

lia of Saturn and Jupiter are ſuch, that the retardations of Saturn ſenſibly exceed the accelerations, and the anomaliſtic period of Saturn increaſes almoſt a day every century; on the contrary, that of Jupiter diminiſhes. M. de la Place ſhows, that this proceeds from the poſition of the aphelia, and the almoſt perfect commenſurability of their revolutions; five revolutions of Jupiter making 21,675 days, while two revolutions of Saturn make 21,538, differing only 137 days.

Suppoſing this relation to be exact, the theory ſhews, that the mutual action of theſe planets muſt produce mutual accelerations and retardations of their mean motions, and aſcertains the periods and limits of the ſecular equations thence ariſing. Theſe periods include ſeveral centuries. Again, becauſe this relation is not preciſe, but the odd days nearly divide the periods already found, there muſt ariſe an equation of this ſecular equation, of which the period is immenſely longer, and the maximum very minute. He ſhews that this retardation of Saturn is now at its maximum, and is diminiſhing again, and will, in the courſe of years, change to an acceleration.

This inveſtigation of the ſmall inequalities is the moſt intricate problem in mechanical philoſophy, and has been completed only by very ſlow degrees, by the arduous efforts of the greateſt mathematicians, of whom M. de la Grange is the moſt eminent. Some of his general reſults are very remarkable.

He demonſtrates, that ſince the planets move in one direction, in orbits nearly circular, no mutual diſturbances make any permanent change in the mean diſtances and mean periods of the planets, and that the periodic changes are confined within very narrow limits.

37 Oſcillation of the planetary ſyſtem.

The orbits can never deviate ſenſibly from circles. None of them ever has been or will be a comet moving in a very eccentric orbit. The ecliptic will never coincide with the equator, nor change its inclination above two degrees. In ſhort, the ſolar planetary ſyſtem oſcillates, as it were, round a medium ſtate, from which it never ſwerves very far.

This theory of the planetary inequalities, founded on the univerſal law of mutual deflection, has given to our tables a preciſion, and a coincidence with obſervation, that ſurpaſſes all expectation, and inſures the legitimacy of the theory. The inequalities are moſt ſenſible in the motions of Jupiter and Saturn; and theſe preſent themſelves in ſuch a complicated ſtate, and their periods are ſo long, that ages were neceſſary for diſcovering them by mere obſervation. In this reſpect, therefore, the theory has outſtripped the obſervations on which it is founded.

38 Authenticity of the Indian aſtronomy.

It is very remarkable, that the periods which the Indians aſſign to theſe two planets, and which appeared ſo inaccurate that they hurt the credit of the ſcience of thoſe ancient aſtronomers, are now found preciſely ſuch as muſt have obtained about three thouſand years before the Chriſtian era; and thus they give an authenticity to that ancient aſtronomy. The periods which any nation of aſtronomers aſſign to thoſe two planets would afford no contemptible mean for determining the age in which it was obſerved.

The following circumſtance is remarkable: Suppoſe Jupiter and Saturn in conjunction in the firſt degree of Aries; twenty years after, it will happen in Sagittarius; and after another twenty years, it will happen in Leo. It will continue in theſe three ſigns for 200 years. In the next 200 it will happen in Taurus, Capricornus, and Virgo; in the next 200 years, it will happen in Gemini, Aquarius, and Libra; and in the next 200 years, it will happen in Cancer, Piſces, and Scorpio: then all begins again in Aries. 39

Origin of the aſtrological diviſion of the heavens.

It is highly probable that theſe remarkable periods of the oppoſitions of Jupiter and Saturn, progreſſive for 40 years, and oſcillating during 160 more, occaſioned the aſtrological diviſion of the heavens into the four *trigons*, of fire, air, earth, and water. Theſe relations of the ſigns, which compoſe a trigon, point out the repetitions of the chief irregularities of the ſolar ſyſtem.

M. de la Place obſerves (in 1796,) that the laſt diſcovered planet gives evident marks of the action of the reſt; and that when theſe are computed and taken into the account of its bygone motions, they put it beyond doubt that it was ſeen by Flamſtead in 1690, by Mayer in 1756, and by Monnier in 1769. 40

Action of the comets.

We have hitherto overlooked the comets in our account of the mutual diſturbances of the ſolar ſyſtem. Their number is very great, and they go to all quarters of the univerſe: but we may conclude, from the wonderful regularity of the planetary motions, when all their own mutual actions are taken into account, that the quantity of matter in the comets is very inconſiderable. They remain but a ſhort time in the neighbourhood of the planets, and they paſs them with great rapidity. Some of them have come very near to Jupiter, but left no trace of their action in the motions of his ſatellites. They doubtleſs contribute, in general, to make the apſides of the planetary orbits advance. 41

They are affected by the planets.

On the other hand, the comets may be conſiderably affected by the planets. The very important phenomenon of the return of the comet of 1682, which was to decide whether they were revolving planets deſcribing ellipſes, or bodies which came but once into the planetary regions, and then retired for ever, cauſed the aſtronomers to conſider this matter with great care. Halley had ſhown, in a rough way, that this comet muſt have been conſiderably affected by Jupiter. Their motion near the aphelion muſt be ſo very ſlow, that a very ſmall change of velocity or direction, while in the planetary regions, muſt conſiderably affect their periods. Halley thought that the action of Jupiter might change it half a year. Mr Clairaut, by conſidering the diſturbing forces of Jupiter and Saturn through the whole revolution, ſhowed that the period then running would exceed the former nearly two years (618 days), and aſſigned the middle of April 1759 for the time of its perihelion. It really paſſed its perihelion on the 12th of March. This was a wonderful preciſion, when we reflect that the comet had been ſeen but a very few days in its former apparitions.

A comet obſerved by Mr Proſperin and others in 1771 has greatly puzzled the aſtronomers. Its motions appear to have been extremely irregular, and it certainly came ſo near Jupiter, that his momentary influence was at leaſt equal to the ſun's. It has not been recogniſed ſince that time, although there is great probability that it is continually among the planets. 42

Conſequence of a comet and planet meeting.

It is by no means impoſſible, nor highly improbable, that in the courſe of ages, a comet may actually meet one of the planets. The effect of ſuch a concourſe muſt be dreadful; a change of the axis of diurnal rotation muſt reſult from it, and the ſea muſt deſert its former bed

bed and overflow the new equatorial regions. The shock and the deluge must destroy all the works of man, and most of the race. The remainder, reduced to misery, must long struggle for existence, and all remembrance of former arts and events must be lost, and every thing must be invented anew. There are not wanting traces of such devastations in this globe: strata and things are now found on mountain tops which were certainly at the bottom of the ocean in former times; remains of tropical animals and plants are now dug up in the circumpolar regions. *Tempora mutantur, et nos mutamur in illis.*

It is plain, that when we know the direction and the intensity of the disturbing force, we can tell what will be the accumulated effect of its action for any time. The direction is easily determined by means of the distance: but how shall we determine the intensity? Since we see that the whole waters of the ocean are deflected toward the moon, and have such probable evidence that planetary deflection is mutual; it follows, that the moon is deflected towards *every* drop of water, and that *all* the matter in one body is deflected towards *all* the matter in another body; and therefore that the deflection towards the sun or a planet is greater or less in proportion to its quantity of matter. Newton indeed thought it unreasonable to suppose that a planet was deflected to the centre of the sun, which had no distinguishing physical property; and thought it more probable that the deflection of a planet to the sun was the accumulated deflection of every particle in the planet to every particle in the sun. But he was too scrupulous to take this for granted. He therefore endeavoured to discover what would be the sensible deflection of one sphere to another, when each consisted of matter, every particle of which was deflected to every particle of the other with an intensity inversely proportional to the square of the distance from it. By help of a most beautiful and simple process, he discovered, that the tendency of a particle of matter to a spherical surface, shell, or solid, of uniform density at equal distances from the centre, was the same as if all the particles in the surface, shell, or solid, were united in its centre: hence it legitimately followed, that the mutual tendency of spherical surfaces, shells, or solids, was proportional to the quantities of matter in the attracting body, and inversely as the square of the distance of their centres; and thus the law of attraction, competent to every particle of planetary matter, was the same with that which *was observed* among spherical bodies consisting of such matter. And it is remarkable, that the inverse duplicate ratio of the distances is the only law that will hold, both with respect to single particles and to globes composed of such particles. He also demonstrated, that a particle placed within a sphere was not affected by all the shell, which was more distant than itself from the centre, being equally attracted on every side, and that it tended toward the centre of a homogeneous sphere, on the surface of which it was placed, with a force proportional to its distance from the centre.

43 Tendency of spherical bodies towards each other, directly as the quantity of matter, and inversely as the square of the distance of their centres.

Newton saw a case in which it was possible to discover whether the tendency of the matter of which the planets consisted was directed to a mathematical centre void of any physical properties, or whether it was the result of its united tendency to all the matter of the planet. He demonstrated, that if the earth consisted of matter which tended to the centre, it behoved it to assume the form of an elliptical spheroid, in consequence of the centrifugal force arising from its diurnal motion, and that the polar axis must be to its equatorial diameter as 577 to 578; but if every particle tends to every other particle in the inverse duplicate ratio of the distance from it, the form must still be elliptical, but more protuberant, and the polar axis must be to the equatorial diameter as 230 to 231. Then only will a column of water from the pole to the centre balance a column from the equator to the centre. He also shewed what should be the vibrations of pendulums in different latitudes, on both suppositions. Mathematicians were eager therefore to make those experiments on pendulums, and to determine the figure of the earth by the measurement of degrees of the meridian in different latitudes. The result of their endeavours has been decidedly in favour of the mutual tendency of all matter. This has been farther confirmed by the observations of the mathematicians who measured the degrees of the meridian in Peru, and by Dr Maskelyne in Britain, who found that a pendulum suspended in the neighbourhood of a great and solid mountain, sensibly deviated from the true vertical, and was deflected toward the mountain.

44 Proportional quantities of matter in the sun and planets determined.

From a collective view of all these circumstances, Sir Isaac Newton concluded, with great confidence, that the deflection toward any planet was the united deflection toward every particle of matter contained in it.

This enabled him to determine the intensity of the planetary disturbing forces, by previously ascertaining the proportions of their quantities of matter. This proportion, the discovery of which seems above our reach, is easily ascertained in all those bodies which have others revolving round them: for the deflection of the revolving body, being occasioned by all the matter in the central body, will be proportional *(cæteris paribus)* to the quantity of matter in the central body, and therefore will give us a measure of that quantity. Would we compare the quantity of matter in Jupiter with the quantity of matter in the sun, we have only to suppose that a planet revolves round the sun at the distance of Jupiter's fourth satellite. Kepler's third law will tell us the time of its revolution. The distances, in this case, being the same, the centripetal forces, and consequently the quantities of matter in the central bodies, will be inversely as the squares of the periodic times of the revolutions around them. In this way have the quantities of matter been determined for the Sun, the Earth, Jupiter, Saturn, and the last discovered planet. If the quantity in the Earth be considered as the unit, we have,

The Earth	1
The newly discovered planet	17,75
Saturn	86,16
Jupiter	317,1
The Sun	338343.

Thus we see that the sun is incomparably bigger than any planet, having more than a thousand times as much matter as Jupiter, the most massy of them all. There is a considerable uncertainty, however, in the proportion to the sun, because we do not know his distance nearer than within $\frac{1}{100}$th part. The proportions of the rest to each other are more accurate. The quantities of matter in Mercury and Mars can only be guessed at: the quantity in Mercury may be called 0,1, and Mars may

may be called 0,12. Venus is fuppofed nearly equal to the Earth. This is concluded from the effect which fhe produces on the preceffion of the equinoxes and the equation of the fun's motion. The moon is fuppofed to be about $\frac{1}{60}$th of the earth, from the effect fhe produces on the tides and the preceffion of the equinoxes, compared with thofe produced by the fun.

45
Sun's place and the tranfit of a planet determined exactly.

When thefe quantities of matter are introduced into the computation of the planetary inequalities, and the intenfity of the difturbing forces affumed accordingly, the refults of the computations tally fo exactly with obfervation, that we can now determine the fun's place for any moment within two or three feconds of a degree, and are certain of the tranfit of a planet within one beat of the clock!

> HALLEY.

Sir Ifaac Newton having already made the great difcovery of an univerfal and mutual deflection of all the matter in the folar fyftem, was one day fpeculating on this fubject, and comparing it with other deflections which he obferved among bodies, fuch as magnets, &c. He confidered terreftrial gravity as a force of this kind.

46
Progrefs of Newton's difcovery of

By the weight of terreftrial bodies they kept united with the earth. By its weight was the water of the ocean formed into a fphere. This force extended, without any remarkable diminution, to the tops of the higheft mountains. Might it not reach much farther? May it not operate even at the diftance of the moon? In the fame manner that the planetary force deflects the moon from the tangent to her orbit, and caufes her to defcribe an ellipfe, the weight of a cannon ball deflects it from the line of its direction, and makes it defcribe a parabola. What if the deflecting force which incurvates her path towards the earth be the fimple weight of the moon? If the weight of a body be the fame with the general planetary force, it will diminifh as the fquare of its diftance from the earth increafes. Therefore, faid he to himfelf, fince the diftance of the moon from the centre of the earth is about 50 times greater than the diftance of the ftone which I throw from my hand, and which is deflected 16 feet in one fecond, the weight of this ftone, if taken up to the height of the moon, fhould be reduced to the 2500th part, and fhould there deflect $\frac{1}{2500}$th of 16 feet in a fecond; and the moon fhould deflect as much from the tangent in a fecond. Having the dimenfions, as he thought, of the moon's orbit, he immediately computed the moon's deflection in a fecond; but he found it confiderably different from what he wifhed it to be. He therefore concluded that the planetary force was not the weight of the planet. For fome years he thought no more of it; but one day, in the Royal Society, he heard an account read of meafurements of a degree of the meridian, which fhowed him that the radius of the earth and the diftance of the moon were very different from what he had believed them to be. When he went home he repeated his computation, and found, that the deflection of a ftone was to the fimultaneous deflection of the moon as the fquare of the moon's diftance from the centre of the earth to the fquare of the ftone's diftance. Therefore the moon is deflected by its weight; and the fall of a ftone is juft a particular inftance of the exertion of the univerfal planetary force. This computation was but roughly made at firft; but it was this coincidence that excited the philofopher to a more attentive review of the whole fubject. When every circumftance which can affect the refult is taken into account, the coincidence is found to be moft accurate. The fall of the ftone is not the full effect of its weight; for it is diminifhed by the rotation of the earth round its axis: It is alfo diminifhed by the weight of the air which it difplaces: It is alfo diminifhed by its tendency to the moon. On the other hand, the moon does not revolve round the earth, but round a common centre of the earth and moon, and its period is about $\frac{1}{120}$th fhorter than if it revolved round the earth; and the moon's deflection is affected by the fun's difturbing force. But all thefe corrections can be accurately made, and the ratio of the full weight of the ftone to the full deflection of the moon afcertained. This has been done.

Terreftrial gravity therefore, or that power by which bodies fall or prefs on their fupports, is only a particular inftance of that general tendency by which the planets are retained in their orbits. Bodies may be faid to *gravitate* when they give indications of their being *gravis* or heavy, that is, when they fall or prefs on their fupports; therefore the planets may be faid to gravitate when they give fimilar indications of the fame tendency by their curvelineal motions. The general FACT, that the bodies of the folar fyftem are mutually deflected towards each other, may be expreffed by the verbal noun GRAVITATION. Gravitation does not exprefs a quality, but an event, a deflection, or a preffure.

The weight of a terreftrial body, or its preffure on its fupport, is the effect of the accumulated gravitation of all its particles; for bodies of every kind of matter fall equally faft. This has been afcertained with the utmoft accuracy by Sir Ifaac Newton, by comparing the vibrations of pendulums made of every kind of matter. 47
Therefore their united gravitation is proportional to their quantity of matter; and we have concluded, that every atom of terreftrial matter is heavy, and equally heavy. We extend this conclufion to the fun and planets, and fay, that the obferved gravitation of a planet is the united gravitation of every particle. Therefore Sir Ifaac Newton inferred, from a collective view of all the phenomena, that *all matter gravitates to* all matter with a force in the inverfe duplicate ratio of the diftance.

The univerfal law of gravitation,

But we do not think that this inference is abfolutely certain. We acknowledge that the experiments on pendulums, confifting of a vaft variety of terreftrial matter, all of which performed their ofcillations in equal times, demonftrate that the acceleration of gravity on thofe pendulums was proportional to their quantities of matter, and that equal gravitation may be affirmed of all terreftrial matter.

The elliptical motion of a planet is full proof that the accelerating power of its gravity varies in the inverfe duplicate ratio of the diftance; and the proportionality of the fquares of the periods to the cubes of the diftances, fhows that the whole gravitations of the planets vary by the fame law. But this third obfervation of Kepler might have been the fame, although the gravitation of a particle of matter in Jupiter had been equal to that of a particle of terreftrial matter, provided that all the matter in Jupiter did not gravitate. If

$\frac{1}{2}$th

$\frac{1}{25}$th of Jupiter had been ſuch gravitating matter, his deflection from the tangent of his orbit would have been the ſame as at preſent, and the time of his revolution would have been what we obſerve. In order that the third law of Kepler may hold true of the planetary motions, no more is required than that the accumulated gravitation of the planet be proportional to its quantity of matter, and thus the matter which does not gravitate will be compenſated by the ſuperior gravitation of the reſt.

But becauſe we have no authority for ſaying that there is matter which gravitates differently from the reſt, or which does not gravitate, we are entitled to ſuppoſe that gravity operates alike on all matter.

48 Which is the ultimatum of his philoſophy.

And this is the ultimatum of the Newtonian philoſophy, that the ſolar ſyſtem conſiſts of bodies compoſed of matter, every particle of which is, in fact, continually deflected by its weight towards every other particle in the ſyſtem; and that this deflection, or actual deviation, or actual preſſure, tending to deviation from uniform rectilineal motion, is in the inverſe duplicate ratio of the diſtance.

49 Objections to the law of gravitation ill-founded.

This doctrine has been called *the ſyſtem of univerſal gravitation*; and it has been blamed as introducing an unphiloſophical principle into ſcience. Gravitation is ſaid to be an occult quality; and therefore as unfit for the explanation of phenomena as any of the occult qualities of Ariſtotle. But this reproach is unfounded; gravitation does not expreſs any quality whatever, but a matter of fact, an event, an actual deflection, or an actual preſſure, producing an actual deflection of the body preſſed. Theſe are not occult, but matters of continual obſervation. True, indeed, Newton does not deny, although he does not poſitively ſay, that this deflection, preſſure, or gravitation, is an effect having a cauſe. *Gravity* is ſaid to be this cauſe. Gravity is the *being gravis or heavy*, and gravitation is the *giving indications of being heavy*. Heavineſs therefore is the word which expreſſes *gravitas*, and our notion of the cauſe of the planetary deflections is the ſame with our notion of heavineſs. This may be indiſtinct and unſatisfactory to a mind faſtidiouſly curious; but nothing can be more familiar. The planet is deflected, *becauſe it is heavy*. We are ſuppoſed to explain the fall of a ſtone through water very ſatisfactorily, and without having recourſe to any occult quality, when we ſay that it is heavier than the water; and we explain the riſe of a piece of cork, when we ſay that it is not ſo heavy as the water. The explanations of the mutual actions of the planets are equally ſatisfactory, founded on the ſame principles, and equally free from all ſophiſtry or employment of occult cauſes. The weight of a body is not its heavineſs, but the effect of its heavineſs. It is a gravitation, an actual preſſure, indicated by its balancing the ſuppoſed heavineſs of another body, or by its balancing the known elaſticity of a ſpring, or by balancing any other natural power. It is ſimilar to the preſſure which a magnet exerts on a piece of iron. This may perhaps be produced by the impulſe of a ſtream of fluid; ſo may the weight of a heavy body. But we do not concern ourſelves with this queſtion.

50 Our knowledge of that law ſatisfactory.

We gain a moſt extenſive and important knowledge by our knowledge of this univerſal law; for we can now explain every phenomenon, by pointing out how it is contained in this law; and we can predict the whole events of the ſolar ſyſtem with unerring exactneſs. This ſhould ſatisfy the moſt inquiſitive mind.

But, *nitimur in vetitum, ſemper cupimuſque negata.* There ſeems to be a fatal and ruinous diſpoſition in the human mind, a ſort of *priapiſm* of the underſtanding, that is irritated by every interdict of natural imperfection. We would take a microſcope to look at light; we would *know* what *knowing* is, and we would *weigh heavineſs*.

All who are acquainted with the writings of Ariſtotle have ſome notion of his whimſical opinions on this ſubject. He imagines that the planets are conducted in their orbits by a ſort of intelligences, ὥσπερ ψυχαί, which animate the orbs that wheel them round. 51

51 Vain attempts to account for it.

Although this crude conception met with no favour in later times, another, not more reaſonable, was maintained by Leibnitz, who called every particle of matter a *monad*, and gave it a perception of its ſituation in the univerſe, of its diſtance and direction from every other, and a power and will to move itſelf in conformity to this ſituation, by certain conſtant laws. This ὥσπερ ψυχή in the Monad is nothing but an aukward ſubſtitute for the principle of gravitation, which the learned inſiſted that Newton placed in every particle of matter as an innate power, and which they reprobated as unphiloſophical. But in what reſpect this perception and active propenſity is better, we do not perceive. It is more complex, and involves every notion that is reprehenſible in the other; and it offers no better explanation of the phenomena.

But Newton is equally anxious with other philoſophers not to aſcribe gravity to matter as an innate inherent property. In a letter to Dr Bently, he earneſtly requeſts him not to charge him with ſuch an abſurd opinion. It is an avowed principle, that nothing can *act* on any thing that is at a diſtance; and this is conſidered as an intuitive axiom. But it is ſurely very obſcure; for we cannot obtain, or at leaſt convey, clear notions of the terms in which it is expreſſed. The word *act* is entirely figurative, borrowed from animal exertions; it is therefore unlike the expreſſion of any thing intitled to the appellation of *intuitive*. If we try to expreſs it without figure, we find our confidence in its certainty greatly diminiſhed. Should we ſay that the condition of a body A cannot depend on another body B that is at diſtance from it, we believe that no perſon will ſay that he makes this aſſertion from perceiving the abſurdity of the contrary propoſition. In the demonſtration, as it is called, of the perſeverance of a body in a ſtate of reſt, the only argument that is offered is, that no cauſe can be aſſigned why it ſhould move in one direction rather than in another: but ſhould any one ſay that another body is near it, to the right hand, and that this is a ſufficient reaſon for its moving that way, we know no method by which this aſſertion can be ſhown to be falſe.

Such, however, has been the uniform opinion of philoſophers. *Nihil movetur* (ſays Leibnitz) *niſi a contiguo et moto.* The celebrated mathematician Euler having diſcovered, as he thought, the production of a preſſure, like gravity, from motion, ſays, "as motion may ariſe from preſſing powers, ſo we have ſeen that preſſing powers may ariſe from motion. We ſee that both exiſt in the univerſe. It is the buſineſs of a philoſopher to diſcover, by reaſon and obſervation, which is the origin of of the other. It is incompatible with reaſon, that bodies ſhould be poſſeſſed of inherent tendencies; much more that powers ſhould exiſt independently. Farther, that philoſopher muſt be reckoned to have aſſigned the true cauſes of phenomena, who demonſtrates that they ariſe from motion; for motion, once exiſting, muſt be preſerved for ever. In the preſent inſtance (a certain whimſical fact of a ball running round the inſide of a hoop) we ſee how a preſſing power may be derived from motion; but we cannot ſee how powers can exert themſelves, or be preſerved, without motion. Wherefore we may conclude that gravity, and all other powers, are derived from motion; and it is our buſineſs to inveſtigate from what motions of what bodies each obſerved power derives its origin."

Accordingly many attempts have been made to trace the planetary deflections to their origin in the motion of ſome impelling matter; but theſe attempts could not be ſucceſsful, becauſe they are all built on hypotheſes. It has been aſſumed, that there is a matter diffuſed through the celeſtial ſpaces; that this matter is in motion, and by its impulſe moves the planets: but the only reaſon that can be given for the exiſtence of this matter is the difficulty we find in explaining the planetary deflections without it. Even if the legitimate conſequences of this hypotheſis were conſiſtent with the phenomena, we have not advanced in our knowledge, nor obtained any explanation. We have only learned, that the appearances are ſuch as would have obtained had ſuch a matter exiſted and acted in this manner. The obſerved laws of the phenomena are as extenſive as thoſe of the hypotheſis; therefore it teaches us nothing but what we knew without it.

52 Inconſiſtency of ſome of theſe accounts with the phenomena.

But this is not all that can be ſaid againſt thoſe attempts; *their legitimate conſequences are inconſiſtent with the phenomena.* By legitimate conſequences we mean the laws of motion. Theſe muſt be admitted, and are admitted, by the philoſopher who attempts to explain the planetary motions by impulſe. It would be ridiculous to ſuppoſe a matter to fill the heavens, having laws of impulſe different from thoſe that are obſerved by common matter, and which laws muſt be *contrived* ſo as to anſwer the purpoſe. It would be more ſimple at once to aſſign thoſe *pro re nata* laws to the planets themſelves.

Yet ſuch was the explanation which the celebrated Deſcartes offered by his hypotheſis of vortices, in which

53 Vortices of Deſcartes

the planets were immerſed and whirled round the ſun. It is aſtoniſhing that ſo crude a conception ever obtained any partiſans; yet it long maintained its authority, and ſtill has zealous defenders. Till Sir Iſaac Newton ſaw the indiſpenſible neceſſity of mathematical inveſtigation in every queſtion of matter in motion, no perſon had taken the trouble of giving any thing like a diſtinct deſcription of thoſe vortices, the circumſtances of their motion, and the manner of their action; all determined with that preciſion that is required in the explanation: for this muſt always be kept in mind, that we want an explanation of the preciſe motions *which have been obſerved*, and which will enable us to predict thoſe which are yet to happen. Men were contented with ſome vague notion of a *ſort* of ſimilarity between the effects of ſuch vortices and the planetary motions in a few general circumſtances; and were neither at the trouble to conſider how theſe motions were produced, nor how far they tallied with the phenomena. Their account of things was only fit for careleſs chat, but unworthy of the attention of a naturaliſt. But ſince this explanation came from a perſon deſervedly very eminent, it was reſpected by Newton, and he honoured it with a ſerious examination. It is to this examination alone that we are indebted for all the knowledge that we have of the conſtitution of a fluid vortex, of the motions of which it is ſuſceptible, of the manner in which it can be produced, the laws of its circulation, and the effects which it can produce. We have this account in Sir Iſaac Newton's Principles of Natural Philoſophy; and it contains many very curious and intereſting particulars, which have been found of great ſervice in other branches of mechanical philoſophy. But the reſult of the examination was fatal to the hypotheſis; ſhewing that the motions which were poſſible in the vortices, and the effects which they muſt produce, are quite incompatible with the appearances in the heavens. We do not know one perſon who has acquired any reputation as a mechanician that now attempts to defend it; nor do we know of any other perſon beſides Newton who has attempted to explain mathematically how the circulation of a fluid can produce the revolution of a planet, if we except Mr Leibnitz, the celebrated rival of the Britiſh Philoſopher.

54 Examined by Newton.

55 Hypotheſis of Leibnitz.

This gentleman publiſhed in the Leipſic Review in 1689, three years after the publication of the *Principia*, an attempt to explain the elliptical motion of the planets, and the deſcription of areas proportional to the times by the impulſe of a vortex. It muſt not be paſſed over in this place, becauſe it acquired great authority in Germany, and many of that country ſtill affirm that Leibnitz is the diſcoverer of the law of planetary gravitation, and of the mechanical conſtitution of the ſolar ſyſtem. We cannot help thinking this explanation the moſt faulty of any, and a moſt diſingenuous plagiariſm from the writings of Newton.

Mr Leibnitz ſuppoſes a fluid, circulating round the ſun in ſuch a manner that the velocity of circulation in every part is inverſely as its diſtance from the ſun. (*N. B.* Newton had ſhown that ſuch a circulation was poſſible, and that it was the only one which could be generated in a fluid by an action proceeding from the centre). Leibnitz calls this *harmonical circulation.* He ſuppoſes that the planet adopts this circulation in every part of its elliptical orbit, obeying without any reſiſtance the motion of this fluid. He does not aſcribe this to the impulſe of the fluid, ſaying *expreſsly* that the planet follows its motion, *non abrepta tamen, ſed tranquilliter quaſi natante.* The planet therefore has no tendency to perſevere in its former ſtate of motion. Why therefore does it not follow this harmonic motion exactly, and deſcribe a circle *tranquilliter natans?* This is owing, ſays Leibnitz, to its centrifugal force, by which it perſeveres in a ſtate of rectilineal motion. It has no tendency to preſerve its former velocity, but it perſeveres in its former direction. The planet therefore is not like common matter, and has laws of motion peculiar to itſelf; it was needleſs therefore to employ any impulſe to explain its motions. But to proceed: This centrifugal force muſt be counteracted in every point of the orbit. Leibnitz therefore ſuppoſes that it is alſo urged toward the centre by a ſolicitation like gravity or attraction. He calls it the *paracentric force.* He computes what muſt be its intenſity in different parts of the orbit, in order to produce an elliptical motion, and he finds that it muſt be inverſely as the ſquare of the diſtance

diſtance from the centre (for this reaſon he is frequently quoted by Bernoulli, Wolff, and others, as the diſcoverer of the law of gravitation). But Leibnitz arrives at this reſult by means of ſeveral mathematical blunders, either ariſing from his ignorance at that time of fluxionary geometry, or from his perceiving that an accurate procedure would lead him to a concluſion which he did not wiſh: for we have ſeen (and the demonſtration is adopted by Leibnitz in all his poſterior writings of this kind), that if the ordinary laws of motion are obſerved, a body, actuated by this paracentric force alone, will deſcribe an ellipſe, performing both its motion of harmonic circulation, and its motion of approach to and receſs from the centre, without farther help. Therefore, if the harmonic circulation is produced by a vortex, a force inverſely as the ſquare of the diſtance from the centre, combined with the harmonic circulation, will produce a motion entirely different from the elliptical. It is demonſtrated, that the force which is neceſſary for deſcribing circles at different diſtances, with the angular velocity of the different parts of the orbit, is not in the inverſe duplicate, but in the inverſe triplicate, ratio of the diſtances. This muſt have been the nature of his paracentric force, in order to counteract the centrifugal force ariſing from the harmonic circulation. Therefore Leibnitz has not arrived at his concluſion by juſt reaſoning, nor can be ſaid to have diſcovered it. He ſays, *Video hanc propoſitionem innotuiſſe viro celeberrimo Iſaaco Newtono, licet non poſſim judicare quomodo ad eam pervenerit.* This is really ſomewhat like impudence. The *Principia* were publiſhed in 1686. They were reviewed at Leipſic, and the Review publiſhed in 1687. Leibnitz was at that time the principal manager of that Review. When Newton publiſhed, Leibnitz was living at Hanover, and a copy was ſent him, within two months of its publication, by Nicholas Facio, long before the Review. The language of the Review has ſeveral ſingularities, which are frequent in Leibnitz's own compoſition; and few doubt of its being his writing. Beſides, this propoſition in the *Principia* had been given to the Royal Society ſeveral years before, and was in the records before 1684. Theſe were all ſeen by Leibnitz when in England, being lent him by his friend Collins.

56 Diſingenuity of the author.

We think that the opinion which a candid perſon muſt form of the whole is, that Leibnitz knew the propoſition, and attempted to demonſtrate it in a way that would make it paſs for his own diſcovery; or that he only knew the enunciation, without underſtanding the principles. His harmonic circulation is a clumſy way of explaining the proportionality of areas to the times; and even this circulation is borrowed from Newton's diſſertation on the Carteſian vortices, which is alſo contained in the Leipſic Review above mentioned. Leibnitz was by this time a competitor with Newton for the honour of inventing the fluxionary mathematics, and was not guiltleſs of acts of diſingenuity in aſſerting his claim. He publiſhed at the ſame time, in the ſame Review, an almoſt unintelligible diſſertation on the reſiſtance of fluids, which, when examined by one who has learned the ſubject by reading the *Principia* of Newton, affords an enigmatical deſcription of the very theory publiſhed by Newton, as a neceſſary part of his great work.

But beſides all the above objections to Leibnitz's theory of elliptical motion, we may aſk, What is this paracentric force? He calls it like gravity. This is preciſely Newton's doctrine. But Leibnitz ſuppoſes this alſo to be the impulſe of a fluid. It would have been enough had he explained the action of this fluid, without the other circulating harmonically. He defers this explanation, however, to another opportunity. It muſt have very ſingular properties: it muſt impel the planet without diſturbing the other fluid, or being diſturbed by it. He alſo defers to another opportunity the explaining how the ſquares of the periodic times of different planets are proportional to the cubes of the mean diſtances; for this is quite incompatible with the harmonic circulation of his vortex. This would make the ſquares of the periods proportional to the diſtances. He has performed neither of theſe promiſes. Several years after this he made a correction of one of his mathematical blunders, by which he deſtroyed the whole of his demonſtration. In ſhort, the whole is ſuch a heap of obſcure, vague, inconſiſtent aſſumptions, and ſo replete with mathematical errors, that it is aſtoniſhing that he had the ignorance or the effrontery to publiſh it.

57 Hypotheſis of Le Sage.

There is another hypotheſis that has acquired ſome reputation. M. le Sage of Geneva ſuppoſes, that there paſſes through every point of the univerſe a ſtream of fluid, in every direction, with aſtoniſhing velocity. He ſuppoſes that, in the denſeſt bodies, the vacuity is incomparably more bulky than the ſolid matter; ſo that a ſolid body ſomewhat reſembles a piece of wire cage-work. The quantity of fluid which paſſes through will be incomparably greater than that of the intercepted fluid; but the impulſe of the intercepted fluid will be ſenſibly proportional to the quantity of ſolid matter of the body. A ſingle body will be equally impelled in every direction, and will not be moved; but another body will intercept ſome fluid. Each will intercept ſome from the other; and the impulſe on B, that is intercepted by A, will be nearly proportional to the matter in A, and inverſely proportional to the ſquare of its diſtance from B; and thus the two bodies will appear to tend toward each other by the law of gravitation.

M. le Sage publiſhed this in a work called *Chimie Mechanique*, and read lectures on this doctrine for many years in Geneva and Paris to crouded audiences. It is alſo publiſhed by Mr Prevoſt in the Berlin Memoirs, under the name of *Lucrece Newtonien*; and there are many who conſider it as a good explanation of gravitation: for our part, we think it inconceivable. The motions of the planets, with undiminiſhed velocity, for more than four thouſand years, appear incompatible with the impelling power of this fluid, be its velocity what it will. The abſolute preciſion of the law of gravitation which does not ſhow the ſmalleſt error during that time, is incompatible with an impulſe which cannot be *exactly* proportional to the quantity of matter, nor to the reciprocal of the ſquare of the diſtance, nor the ſame on a body moving with the rapidity of the comet of 1680 in its perihelion, as on the planet Saturn, whoſe motion is almoſt incomparably ſlower. What is the origin of the motion of this fluid? Why does it not deſtroy itſelf by mutual impulſe, ſince it is continually paſſing through every point? &c.

58 Ether of Newton ſolves no difficulties.

We have already obſerved that Newton expreſſed the ſame anxiety to avoid the ſuppoſition of action among bodies at a diſtance. *He* alſo *ſeemed* to ſhow ſome diſpoſition to account for gravitation by the action of a contiguous fluid. This is the ſubterfuge ſo much recurred

curred to by precipitate speculatists, by the name of the *ether of Sir Isaac Newton*. He supposes it highly elastic, and much rarer in the pores of bodies and in their vicinity than at a distance; therefore exceedingly rare in the sun, and denser as we recede from him. Being highly elastic, and repelled by all bodies, it must impel them to that side on which it is most rare; therefore it must impel them toward the sun. This is enough of its general constitution to enable us to judge of its fitness for Newton's purpose. It is wholly unfit; for since it is fluid, unequally dense and elastic, its particles are not in contact. Particles that are elastic, and in a state of compression, and in contact, cannot be fluid; they must be like so many blown bladders compressed in a box; therefore they are not in contact; therefore they are elastic by mutual repulsion; that is, by acting on each other at a distance. It is indifferent whether this distance is a million of miles, or the millionth part of a hair's breadth; therefore this fluid does not free Newton from the supposition which he wishes to avoid. Nay, it can be demonstrated, that in order to form a fluid which shall vary in density from the sun to the extremity of the solar system, there must be a mutual repulsion *extending to that distance*. This is introducing millions of millions of the very difficulties which Newton wished to avoid; for each particle presents the same difficulty with a planet.

We would now ask these atomical philosophers, why they have, in all ages, been so anxious to trace the celestial motions to the effects of impulse? They imagine that they have a clear perception of the communication of motion by impulse, while their perception of the production of it in any other way is obscure. Seeing, in a very numerous and familiar collection of facts, that motion *is* communicated by impulse, they think that it is communicated in no other way, and that impulse is the only moving power in nature.

59 Our notion of impulse not clearer than of gravitation.

But is it true that our notion of impulse is more clear than that of gravitation? Its being more familiar is no argument. A cause may be real, though it has exerted itself but once since the beginning of time. In no case do we *perceive* the exertion of the cause; we only perceive the change of motion. The constitution of our mind makes us consider this as an effect, indicating a cause which is inherent in that body which we always see associated with that change. Granting that our perception of the perseverance of matter in its state of motion is intuitive, it by no means follows that the body A in motion must move the body B by striking it. The moment it strikes B, all the metaphysical arguments for A's continuance in motion are at an end, and they are not in the least affected by the supposition that A and B should continue at rest after the stroke; and we may defy any person to give an argument which will prove that B will be moved; nay, the very existence of B may, for any thing we know to the contrary, be a sufficient reason for the cessation of the motion of A. The production of motion in B, by the impulse of A, must therefore stand on the same foundation with every other production of motion. It indicates a moving power in A; but this inherent power seems to have no dependence on the motion of A: (See what is contained in n° 81. of the article Physics, and n° 67. of Optics of the *Encycl.*) We see there a motion produced in B without impulse, and taken from A, similar in every respect to every case of impulse; and we see that the motion of A is necessary for producing such a motion in B as is observed in all cases of impulse, merely in order that the moving power, which is inherent in A, whether it be in rest or in motion, may act during a sufficient time. Our confidence in the communication of motion, in the case mentioned there, is derived entirely from experience, which informs us that A possesses a moving power totally different from impulse. Our belief of the impelling power of matter therefore does not necessarily flow from our intuitive knowledge of the perseverance of matter, although it gives us the knowledge of this perseverance. It is like a mathematical demonstration, a road to the discovery of the property of figure, but not the cause of that property. The impulsion of matter is merely a fact, like its gravitation, and we know no more of the one than of the other.

It is not a clearer perception, therefore, which has procured this preference of impulsion as the ultimate explanation of motion, and has given rise to all the foolish hypotheses of planetary vortices, ethers, animal spirits, nervous fluids, and many other crude contrivances for explaining the abstruse phenomena of nature.

Nor does it deserve any preference on account of its greater familiarity. Just the contrary: for one fact of undoubted impulse, we see millions where no impulse is observed. Consider the motion produced by the explosion of gunpowder. Where is the original impulse? Suppose the impulse of the first spark of fire to be immense, how comes it that a greater impulse is produced by a greater quantity of gunpowder, a greater quantity of quiescent matter? The ultimate impulse on the bullet should be less on this account. Here are plain exertions of moving powers, which are not reducible to impulse. Consider also the facts in animal motion. Reflect also, that there has been more motion, without any observed impulse, produced in the waters of a river since the beginning of the world, than by all the impulse that man has ever observed. Add to these, all the motions in magnetism, electricity, &c. Impulse is therefore a phenomenon which is comparatively rare. 60 Impulse rarely observed.

Have we ever observed motion communicated by pure impulse, without the action of forces at a distance? This appears to us very doubtful. Every one acquainted with Newton's discoveries in optics will grant, that the colours which appear between two object-glasses of long telescopes, when they are pressed together, demonstrate, that the glasses do not touch each other, except in the place where there is a black spot. It requires more than a thousand pounds to produce a square inch of this spot. Therefore every communication of motion between two pieces of glass, which can be produced by one of them striking the other, is produced without impulse, unless their mutual pressure has exceeded 1000 pounds on the square inch of the parts which act on each other. Nay, since we see that a black spot appears on the top of a soap bubble, in the middle of the coloured rings, we learn that there is a certain thickness at which light ceases to be visibly reflected; therefore the black spot between the glasses does not prove that they touch in that part; therefore we cannot say that any force whatever can make them touch. The ultimate repulsion may be insuperable. If this be the case, the production of motion by impulse is, in every instance, like the production of motion between the magnets in n° 81. of the article Physics in the Encycl.

and

and is of the ſame kind with the production of motion by gravity.

61 Intervening fluids multiply difficulties.

Therefore no explanation of gravitation can be derived from any hypotheſis whatever of intervening fluids. They only ſubſtitute millions of bodies for one, and ſtill leave the action *e diſtanti* the ſame difficulty as before. It is not in the leaſt neceſſary that we ſhall be able to conceive how a particle of matter can be influenced by another at a diſtance; if we have diſcovered in every inſtance the preciſe degree and direction of the effect of this influence, we have made a moſt important addition to our knowledge of nature; and our ſucceſs in the caſe of the power of gravity ſhould make us aſſiduous in our endeavours to diſcover, from the phenomena, the laws which regulate the other actions *e diſtanti*, which obſervation is daily finding out. A knowledge equally accurate of the law of magnetic and electric action may enable us to give theories of magnetiſm and electricity equally exact with the Newtonian theory of gravitation.

Having, we hope, evinced the truth of this theory, by following out the inveſtigations to which Newton was gradually led, we might proceed to conſider, in order, the complicated and ſubordinate phenomena which depend on it. The lunar and planetary inequalities are the ſubjects that naturally come firſt in our way; but they have already been explained in all the detail that this conciſe account will admit, as they occurred to Newton as teſts of the truth of his conjecture. If the law be ſuch as he ſuſpected, its conſequences muſt be ſo and ſo; if the celeſtial motions do not agree with them, the law muſt be rejected. We ſhall not repeat any thing therefore on this head, but confine our obſervations to ſuch applications of the theory of univerſal gravitation as newly diſcovered objects, or the improvement of aſtronomical obſervation and of fluxionary analyſis, have enabled us to make ſince the time of Newton.

The ſubſerviency of the eclipſes of Jupiter's ſatellites to geography and navigation had occaſioned their motions to be very carefully obſerved, ever ſince theſe uſes of them were firſt ſuggeſted by Galileo, and their theory is as far advanced as that of the primary planets. It has peculiar difficulties. Being very near to Jupiter, the great deviation of his figure from perfect ſphericity makes the relation between their diſtances from his centre and their gravitations toward it vaſtly complicated. But this only excited the mathematicians ſo much the more to improve their analyſis; and they ſaw, in this little ſyſtem of Jupiter and his attendants, an epitome of the ſolar ſyſtem, where the great rapidity of the motions muſt bring about in a ſhort time every variety of configuration or relative poſition, and thus give us an example of theſe mutual diſturbances of the primary planets, which require thouſands of years for the diſcovery of their periods and limits. We have derived

62 Eternal durability of the ſolar ſyſtem

ſome very remarkable and uſeful pieces of information from this inveſtigation; and have been led to the diſcovery of the eternal durability of the ſolar ſyſtem, a thing which Newton greatly doubted of.

Mr Pound had obſerved long ago, that the irregularities of the three interior ſatellites were repeated in a period of 437 days; and this obſervation is found to be juſt to this day.

247 revolutions of the firſt occupy		437 d.	3 h.	44′
123	ſecond	437	3	42
61	third	437	3	36
26	fourth	435	14	16

This naturally led mathematicians to examine their motions, and ſee in what manner their relative poſitions or configurations, as they are called, correſponded to this period: and it is found, that the mean longitude of the firſt ſatellite, *minus* thrice the mean longitude of the ſecond, *plus* twice the mean longitude of the third, always made 180 degrees. This requires that the mean motion of the firſt, added to twice that of the third, ſhall be equal to thrice the mean motion of the ſecond. This correſpondence of the mean motions is of itſelf a ſingular thing, and the odds againſt its probability ſeems infinitely great; and when we add to this the particular poſitions of the ſatellites in any one moment, which is neceſſary for the above conſtant relation of their longitudes, the improbability of the coincidence, as a thing quite fortuitous, becomes infinitely greater. Doubts were firſt entertained of the coincidence, becauſe it was not indeed accurate to a ſecond. The reſult of the inveſtigation is curious. When we follow out the conſequences of mutual gravitation, we find, that although neither the primitive motions of projection, nor the points of the orbit from which the ſatellites were projected, were *preciſely* ſuch as ſuited theſe obſerved relations of their revolutions and their contemporaneous longitudes; yet, if they differed from them only by very minute quantities, the mutual gravitations of the ſatellites would in time bring them into thoſe poſitions, and thoſe ſtates of mean motion, that would induce the obſerved relations; and when they are once induced they will be continued for ever. There will indeed be a ſmall equation, depending on the degree of unſuitableneſs of the firſt motions and poſitions; and this cauſes the whole ſyſtem to oſcillate, as it were a little, and but a very little way on each ſide of this exact and permanent ſtate. The permanency of theſe relations will not be deſtroyed by any ſecular equations ariſing from external cauſes; ſuch as the action of the fourth ſatellite, or of the ſun, or of a reſiſting medium; becauſe their mutual actions will diſtribute this equation as it did the original error.

This curious reſult came into view only by degrees, as analyſis improved and the mathematicians were enabled to manage more complicated formulas, including more terms of the infinite ſerieſes that were employed to expreſs the different quantities. It is to M. de la Grange that we are indebted for the completion of the diſcovery of the permanency of the ſyſtem in a ſtate very little different from what obtains in any period of its exiſtence. Although this required all the knowledge and addreſs of this great mathematician, in the management of the moſt complicated analyſis, the evidence of its truth may be perceived by any perſon acquainted with the mere elements of fluxionary geometry. The law of the compoſition of forces enables us to expreſs every action of the mutual forces of the ſun and planets by the ſines and coſines of circular arches, which increaſe with an uniform motion, like the perpetual lapſe of time. The nature of the circle ſhows, that the variations of the ſines and coſines are proportional to the coſines and ſines of the ſame arches. The variations of their ſquares, cubes, or other powers, are proportional to the ſines or coſines of the doubles or triples, or other multiplies of the ſame arches. Therefore ſince the infinite ſerieſes which expreſs thoſe actions of forces, and their variations, include only ſines and coſines, with their powers and fluxions, it follows, that all accumulated

lated forces, and variations of forces, and variations of variations, through infinite orders, are still expressible by repeated sums of sines or cosines, corresponding to arches which are generated by going round and round the circle. The analyst knows that these quantities become alternately positive and negative; and therefore, in whatever way they are compounded by addition of themselves, or their multiples, or both, we must always arrive at a period after which they will be repeated with all their intermediate variations. It may be extremely difficult, it may be impossible, in our present state of mathematical knowledge, to ascertain all those periods. It has required all the efforts of all the geniuses of Europe to manage the formulas which include terms containing the fourth and fifth powers of the eccentricities of the planetary orbits. Therefore the periods which we have already determined, and the limits to which the inequalities expressed by secular equations arrive, are still subjected to smaller corrections of incomparably longer periods, which arise from the terms neglected in our formulas. But the correction arising from any neglected term has a period and a limit; and thus it will happen that the system works itself into a state of permanency, containing many intervening apparent anomalies. The elliptical motion of the earth contains an anomaly or deviation from uniform circular motion; the action of Jupiter produces a deviation from this elliptical motion, which has a period depending on the configuration of the three bodies; Saturn introduces a deviation from this motion, which has also a period; and so on.

There is another accurate adjustment of motions which has attracted attention, as a thing in the highest degree improbable, in events wholly independent on each other. This is the exact coincidence of the period of the moon's revolution round the earth with that of her rotation round her own axis. The ellipticity or oval shape of the moon differs so insensibly from a sphere, that if the original rotation had differed considerably from the period of revolution, the pendular tendency to the earth could never have operated a change: but if the difference between those two motions was so small, that the pendular tendency to the line joining the centres of the earth and moon was able to overcome it after some time, the pole of the lunar spheroid would deviate a little from the line joining the earth and moon, and then be brought back to it with an accelerated motion; would pass it as far on the other side, and then return again, vibrating perpetually to each side of the mean position of the *radius vector*. The extent of this vibration would depend on the original difference between the motion of rotation and the mean motion of revolution. This difference must have been very small, because this *pendular vibration* is not sensible from the earth. The observed LIBRATION of the moon is precisely what arises from the inequality of her orbital motion. For the same reasons, the effects of the secular equations of the moon (which would, in the course of ages, have brought her whole surface into our view, had her rotation been strictly uniform) are counteracted by her pendular tendency, which has a force sufficient to alter her rotation by nearly the same slow and insensible changes that obtain in her mean motions. The same causes also preserve the nodes of her equator and of her orbit in the same points of the ecliptic. The complete demonstration of this is perhaps the most delicate and elegant specimen that has been given of the modern analysis. We owe it to M. de la Grange: and he makes it appear that the figure of the moon is not that which a fluid sphere would acquire by its gravitation to the earth; it must be the effect of a more considerable ellipticity, or internal inequality of density.

63 Depends on the law of planetary deflection,

This permanency of the system, within very narrow limits of deviation from its present state, depends entirely on the law of planetary deflection. Had it been directly or inversely as the distance, the deviations would have been such as to have quickly rendered it wholly unfit for its present purposes. They would have been very great, had the planetary orbits differed much from circles; nay, had some of them moved in the opposite direction. The selection of this law, and this form of the orbits, strikes the mind of a Newton, and indeed any heart possessed of sensibility to moral or intellectual excellence, as a mark of wisdom prompted by benevolence. But De la Place and others, infected with the *Theophobia Gallica* engendered by our licentious desires, are eager to point it out as a mark of fatalism. They say, that it is essential to all qualities that are diffused from a centre to diminish in the inverse duplicate ratio of the distance. But this is false, and *very false*: it is a mere geometrical conception. We indeed say, that the density of illumination decreases in this proportion; but who says that this is a quality? Whether it be considered as the emission of luminous corpuscles, or an undulation of an elastic fluid, it is not a quality emanating from a centre: and even in this estimation, it seems gratuitous, whether we shall consider the base of the luminous pyramid, or its whole contents, as the expression of the quantity. Nay, if all qualities must diminish at this rate, all action *e distanti* must do the same; for when the distances bear any great proportion to the diameters of the particles, their action deviates insensibly from this law, and is perceived only by the accumulation of its effects after a long time. It is only thus that the effects of the oblate figure of Jupiter are perceived in the motion of his satellites. The boasted sound philosophy which sees fatal necessity where the *most successful students of nature* saw moral excellence, has derived very little credit or title to the name of *wisdom*, by letting loose all those propensities of the human heart which are essentially destructive of social happiness.

64 And evinces the wisdom of the Creator.

These propensities were always known to lurk in the heart of man; and those surely were the wisest who laboured to keep them in check by the influence of moral principles, and particularly by cherishing that disposition of the human heart which prompts us to see contrivance wherever we see nice and refined adjustment of means to ends; and, from the admirable beauty of the solar system, to cry out,

"These are thy glorious works, Parent of good!
"Almighty, thine this universal frame,
"Thus wond'rous fair; thyself how wond'rous then!
"Unspeakable, who sitt'st above these heavens,
"To us invisible, or dimly seen
"In these thy lowest works; yet these declare
"Thy goodness beyond thought, and power divine."
Par. Lost, b. v.

"But wandering oft, with brute unconscious gaze,
"Man marks not THEE, marks not the mighty hand
"That, ever busy, wheels the silent spheres."
THOMPSON.

The

The moſt important addition (in a philoſophical view) that has been made to aſtronomical ſcience ſince the diſcovery of the aberration of light and the nutation of the earth's axis, is that of the rotation of Saturn's ring.

65 Saturn's ring.

The ring itſelf is an object quite ſingular; and when it was diſcovered that all the bodies which had any immediate connection with a planet were heavy, or gravitated toward that planet, it became an intereſting queſtion, what was the nature of this ring? what ſupported this immenſe arch of heavy matter without its reſting on the planet? what maintains it in perpetual concentricity with the body of Saturn, and maintains its ſurface in one invariable poſition?

The theory of univerſal gravitation tells us what things are poſſible in the ſolar ſyſtem; and our conjectures about the nature of this ring muſt always be regulated by the circumſtance of its gravitation to the planet. Philoſophers had at firſt ſuppoſed it to be a luminous atmoſphere, thrown out into that form by the great centrifugal force ariſing from a rotation: but its well defined edge, and, in particular, its being two very narrow rings, extremely near each other, yet perfectly ſeparate, rendered this opinion of its conſtitution more improbable.

66 Diſcovery of Dr Herſchel relating to it.

Dr Herſchel's diſcovery of brighter ſpots on its ſurface, and that thoſe ſpots were permanent during the whole time of his obſervation, ſeems to make it more probable that the parts of the ring have a ſolid connection. Mr Herſchel has diſcovered, by the help of thoſe ſpots, that the ring turns round its axis, and that this axis is alſo the axis of Saturn's rotation. The time of rotation is 10h. $32\frac{1}{4}'$. But the other circumſtances are not narrated with the preciſion ſufficient for an accurate compariſon with the theory of gravity. He informs us, that the radii of the four edges of the ring are 590 751, 774, 830, of a certain ſcale, and that the angle ſubtended by the ring at the mean diſtance from the earth is $46\frac{7}{4}''$. Therefore its elongation is $23\frac{1}{4}''$. The elongation of the ſecond Caſſinian ſatellite is 56″, and its revolution is 2d. 17h. 44′. This ſhould give, by the third law of Kepler, 17h. 10′ for the revolution of the outer edge of the ring, or rather of an atom of that edge, in order that it may maintain itſelf in equilibrio. The ſame calculation applied to the outer edge of the inner ring gives about 13h. 36′; and we obtain 11h. 16′ for the inner edge of this ring. Such varieties are inconſiſtent with the permanent appearance of a ſpot. We may ſuppoſe the ring to be a luminous fluid or vapour, each particle of which maintains is ſituation by the law of planetary revolution. In ſuch a ſtate, it would conſiſt of concentric ſtrata, revolving more ſlowly as they were more remote from the planet, like the concentric ſtrata of a vortex, and therefore having a relative motion incompatible with the permanency of any ſpot. Beſides, the rotation obſerved by Herſchel is too rapid even for the innermoſt part of the ring. We think therefore that it conſiſts of cohering matter, and of conſiderable tenacity, at leaſt equal to that of a very clammy fluid, ſuch as melted glaſs.

We can tell the figure which a fluid ring muſt have, ſo that it may maintain its form by the mutual gravitation of its particles to each other, and their gravitation to the planet. Suppoſe it cut by a meridian. It may be in equilibrio if the ſection is an ellipſe, of which the longer axis is directed to the centre of the planet, and very ſmall in compariſon with its diſtance from the centre of the planet, and having the revolution of its middle round Saturn, ſuch as agrees with the Keplerean law. Theſe circumſtances are not very conſiſtent with the dimenſions of Saturn's inner ring. The diſtance between the middle of its breadth and the centre of Saturn is 670, and its breadth is 161′, nearly one-fourth of the diſtance from the centre of Saturn. De la Place ſays, that the revolution of the inner ring obſerved by Herſchel is very nearly that required by Kepler's law: but we cannot ſee the grounds of this aſſertion. The above compariſons with the ſecond Caſſinian ſatellite ſhows the contrary. The elongation of that ſatellite is taken from Bradley's obſervations, as is alſo its periodic time. A ring of detached particles revolving in 10h. $32\frac{1}{4}'$ muſt be of much ſmaller diameter than even the inner edge of Saturn's ring. Indeed, the quantity of matter in it might be ſuch as to increaſe the gravitation conſiderably; but this would be ſeen by its diſturbing the ſeventh and ſixth ſatellites, which are exceedingly near it. We cannot help thinking therefore that it conſiſts of matter which has very conſiderable tenacity.

67 Its probable conſiſtency

An equatorial zone of matter, tenacious like melted glaſs, and whirled briſkly round, might be thrown off, and, retaining its great velocity, would ſtretch out while whirling, enlarging in diameter and diminiſhing in thickneſs or breadth, or both, till the centrifugal force was balanced by the united force of gravity and tenacity. We find that the equilibrium will not be ſenſibly diſturbed by conſiderable deviations, ſuch as unequal breadth, or even want of flatneſs. Such inequalities appear on this ring at the time of its diſparition, when its edge is turned to the ſun or to us. The appearances of its different ſides are then conſiderably different.

Such a ring or rings muſt have an oſcillatory motion round the centre of Saturn, in conſequence of their mutual action, and the action of the ſun, and their own irregularities: but there will be a certain poſition which they have a tendency to maintain, and to which they will be brought back, after deviating from it, by the ellipticity of Saturn, which is very great. The ſun will occaſion a nutation of Saturn's axis and a preceſſion of his equinoxes, and this will drag along with it both the rings and the neighbouring ſatellites.

The atmoſphere which ſurrounds a whirling planet cannot have all its parts circulating according to the third law of Kepler. The mutual attrition of the planet, and of the different ſtrata, ariſing from their different velocities, muſt accelerate the ſlowly moving ſtrata, and retard the rapid, till all acquire a velocity proportional to their diſtance from the axis of rotation; and this will be ſuch that the momentum of rotation of the planet and its atmoſphere remains always the ſame. It will ſwell out at the equator, and ſink at the poles, till the centrifugal force at the equator balances the weight of a ſuperficial particle. The greateſt ratio which the equatorial diameter can acquire to the polar axis is that of four to three, unleſs a coheſive force keeps the particles united, ſo that it conſtitutes a liquid, and not an elaſtic fluid like air; and an elaſtic fluid cannot form an atmoſphere bounded in its dimenſions, unleſs there be a certain rarity which takes away all elaſticity. If the equator ſwells beyond the dimenſion which makes the gravitation balance the centrifugal force, it muſt immediately diſſipate.

If we ſuppoſe that the atmoſphere has extended to this limit, and then condenſes by cold, or any chemical or other caufe different from gravity, its rotation neceffarily augments, preferring its former momentum, and the limit will approach the axis; becaufe a greater velocity produces a greater centrifugal force, and requires a greater gravitation to balance it. Such an atmofphere may therefore defert, in fucceffion, zones of its own matter in the plane of its equator, and *leave* them revolving in the form of rings. It is not unlikely that the rings of Saturn may have been furnifhed in this very way; and the zones, having acquired a common velocity in their different ftrata, will preferve it; and they are fufceptible of irregularities arifing from local caufes at the time of their feparation, which may afford permanent fpots.

68 And origin.

69 It may furnifh the means of difcovering the nature of light.

We think that the rotation of Saturn's ring affords fome hopes of deciding a very important queftion about the nature of light. If light be the propagation of elaftic undulations, its velocity depends entirely on the elafticity and denfity of the fluid; but if it be the emiffion of corpufcles, their velocity may be affected by other caufes. The velocity of Saturn's ring is $\frac{59}{63}$ of that of the earth in its orbit, and therefore about $\frac{1}{10000}$ of the velocity of light. The weftern extremity (to us in the northern regions) is moving from us, and the eaftern is moving toward us. If light, by which we fee it, be reflected like an elaftic ball from an elaftic body, there will be an excefs in the velocity of the light by which we fee the eaftern limb above the velocity of the light by which we fee the weftern limb. This excefs will be $\frac{1}{2500}$ of the mean velocity of light. This fhould be difcovered by a difference in the refraction of the two lights. If an acromatic prifm could be made to refract fourteen degrees, and if Saturn be viewed thro' a telefcope with this prifm placed before it, there fhould be a change of fhape amounting to fixteen feconds; if the axis of the prifm be parallel to the longer axis of the ring, it will diftort it prodigioufly, and give it an oblique pofition.

A fimilar effect will be produced by placing the prifm between the eye-glafs and the image in the focus of the object-glafs.

Our expectation is founded on this unqueftionable principle in dynamics, that when a particle of light paffes through the active ftratum of a tranfparent body which refracts light toward the perpendicular, the addition made to the fquare of its velocity by the refracting forces is equal to the fquare of the velocity which thofe forces would communicate to a particle at reft on the furface of this refracting ftratum of the tranfparent body. Therefore if the velocity of the incident light be increafed, the ratio of the fine of incidence to the fine of refraction will be diminifhed. It is confonant to common fenfe, that when the incident light has a greater velocity, it paffes more rapidly through the attracting ftratum, and a fmaller addition is made to the velocity. When the velocity of the incident light is 10000 times greater than that of the earth's annual motion, the fine of incidence is to the fign of refraction in glafs as 20 to 31, or as 10000 to 15500. If this be increafed $\frac{1}{2500}$, making it 10004, the ratio will be that of 10004 to 15502,62, or of 10000 to 15496.4. The difference between the refractions of the light from the eaftern and weftern extremities of the ring will be, to all fenfe, the fame, if the velocity of the one be diminifhed to 9998, and the other increafed to 10002.

We may juft add here, by the way, that the action of another body may confiderably change the conftitution of this atmofphere. Thus, fuppofing that the moon had originally an atmofphere, the limit will be that diftance from the moon where the centrifugal force, arifing from the moon's rotation, added to the gravitation to the earth, balances the gravitation to the moon. If the moon be $\frac{1}{39}$th of the earth, this limit will be about $\frac{1}{9}$th of the moon's diftance from the earth. If at this diftance the elafticity of the atmofphere is not annihilated by its rarefaction, it will be all taken off by the earth, and accumulate round it. This may be the reafon why we fee no atmofphere about the moon.

70 Probable reafon why we fee no atmofphere about the moon.

What has been faid in the article TIDE (Encycl.), will explain the trade-winds on the earth and in Jupiter and Saturn. On the earth they are increafed by the expanfion of the air by heat. This caufes it to rife in the parts warmed by the fun, and flow off toward the poles, where it is again cooled and condenfed. The under ftratum of colder and denfer air is continually flowing in from the poles. This having lefs velocity of circulation than the equatorial parts of the earth, muft have a relative motion contrary to that of the earth, or from eaft to weft, and this muft augment the current produced by gravitation.

THUS we fee that all the mechanical phenomena of the folar fyftem, whether relating to the revolutions round the various centres of gravitation, or to the figure of the planets and the ofcillations of the fluids which cover them, or to the rotations round their refpective axes—are neceffary confequences of one fimple principle of a gravitation in every particle, decreafing in the reciprocal duplicate ratio of the diftance. We fee that this, combined with a primitive projection, will produce every motion that we obferve. It was not neceffary, as Copernicus imagined, to imprefs three motions on the earth; one, by which it was made to revolve round the fun; a fecond, caufing it to turn round an axis inclined to that of its orbit; and a third, by which this axis defcribed that conic furface which forms the preceffion of the equinoxes. One impulfe, not paffing through the centre of the earth, nor in the plane of the ecliptic, will produce the two firft motions, and the protuberant matter produced by the rotation will generate the third motion, by the tendency of its parts to the other heavenly bodies. Without this principle, the elliptic motion of the planets and comets, their various inequalities, fecular or periodical, thofe of the moon and of the fatellites of Jupiter, the preceffion of the equinoxes, the nutation of the earth's axis, the figure of the earth, the undulations of its ocean—all would have been imperfectly known, as matters of fact, wholly different from each other, and folitary and unconnected. It is truly deferving admiration, that fuch an immenfe variety of important phenomena flow fo palpably from one principle, of fuch fimplicity, and fuch univerfality, that no phenomenon is now left out unexplained, and predicted with a certainty almoft equal to actual obfervation.

71 All the mechanical phenomena of the folar fyftem flow from one fimple principle.

Quæ toties animos veterum torfêre fophorum,

ASTROTHEMATA, the places or positions of the stars, in an astrological scheme of the heavens.

ASTROTHESIA, is used by some for a constellation or collection of stars in the heavens.

ASTRUM, or ASTRON, a constellation or assemblage of stars: in which sense it is distinguished from *Aster*, which denotes a single star. Some apply the term, in a more particular sense, to the Great Dog, or rather to the large bright star in his mouth.

ASYMMETRY, the want of proportion, otherwise called *incommensurability*, or the relation of two quantities which have no common measure, as between 1 and $\sqrt{2}$, or the side and diagonal of a square.

ASYMPTOTES, (see Encycl.) are, by some, distinguished into various orders. The asymptote is said to be of the first order, when it coincides with the base of the curvilinear figure; of the second order, when it is a right line parallel to the base; of the third order, when it is a right line oblique to the base; of the fourth order, when it is the common parabola, having its axis perpendicular to the base; and, in general, of the $n+2$ order, when it is a parabola whose ordinate is always as the n power of the base. The asymptote is oblique to the base, when the ratio of the first fluxion of the ordinate to the fluxion of the base approaches to an assignable ratio, as its limit; but it is parallel to the base, or coincides with it, when this limit is not assignable.

ATTAR OF ROSES. See *Roses, Otter of*, both in the Encyclopædia and in this Supplement.

AVANT-FOSS, or *Ditch of the Counterscarp*, in fortification, is a wet ditch surrounding the counterscarp on the outer side, next to the country, at the foot of the glacis. It would not be proper to have such a ditch if it could be laid dry, as it would then serve as a lodgment for the enemy.

AVALON, a peninsula at the S. E. corner of the island of Newfoundland, which is joined to the island by a narrow neck of land, that has Placentia Bay on the S. and Trinity Bay on the N. The E. part of this peninsula is encompassed by the Great Bank, and has, besides the two former bays, the bay of Conception on the N. and the bay of St Mary's and Trepassy bay on the S. It contains several excellent harbors, bays and capes, among which are St Mary's, Pine, Race, Ballard, St Francis, &c.—*Morse*.

AUBIGNE. See STUART in this supplement.

AVES, or *Bird's Island*, in the West Indies, situated in N. lat. 15. 30. W. long. 63. 15. named so from the great number of birds that breed there, yet is without a tree, which obliges them to lay their eggs in the sand. A shoal runs from hence to the islands of Saba, St Eustatius, and St Christophers; which is about 2 leagues broad, and from 10 to 20 fathom soundings.

There is another island of this name, among the Little Antilles, between the coast of St Jago de Leon, in Terra Firma, and the island of Bonaire.—*Morse*.

AUGUSTA *Co.* in Virginia, has Albemarle co. on the E. Part of it lies E. and part W. of the North Mt. a ridge of the Allegany. The soil is fertile, and the county contains 10,886 inhabitants, including 1567 slaves.

Here is a remarkable cascade, called the *Falling Spring*. It is a branch of the James, where it is called Jackson's River rising in the mountains 20 miles S. W. from the *Warm Spring*, or *Hot Spring*, which lies in N. lat. 38. 9. W. long. 80. 6. At the *Falling Spring*, the water falls 200 feet; which is about 50 feet higher than the fall of Niagara. Between the sheet of water and the rock below, a man may walk across dry. The sheet of water is only 12 or 15 feet wide above and somewhat wider below. It is broken in its breadth in two or three places, but not at all in its height.—*ib.*

AUGUSTA, in the Upper District of Georgia, was till lately the seat of government. It is situated on a fine plain in Richmond co. on the S. W. bank of Savannah R. where it is nearly 500 yards broad, at a bend of the river, 127 miles N. W. from Savannah; from Washington S. E. by E. and from Louisville S. westerly, 50 miles; and 934 miles S. W. from Philadelphia.

At the first settlement of the colony, Gen. Oglethorpe erected a fort here, for protecting the Indian trade, and holding treaties with the natives. In 1739, about 600 people separated themselves from the maritime settlements, and removed to its neighbourhood to carry on a peltry trade with the Indians. There were, however, but 3 or 4 houses in the town of Augusta in 1780, and in 1787 it contained 200. The country round it has an excellent soil, which with its central situation between the upper and lower countries, will bring it fast into importance. N. lat. 33. 19. W. long. 80. 46.—*ib.*

AUMIL, in Bengal, a native collector or manager of a district on the part of government.

AVON, a river of Nova-Scotia, which empties into the Atlantic Ocean a little eastward of Halifax. It is navigable as far as Fort Edward for vessels of 400 tons, and for vessels of 60 tons 2 miles higher. A river called St Croix runs into the Avon, whose source is in lakes and springs, about 7 miles from its entrance, where it is crossed by a bridge on the road leading to Windsor. It is navigable for vessels of 60 tons 3 miles, and for large boats 7 miles.—*Morse*.

AURELIUS, a military township in New-York, in Onondaga co. on Owasco Lake having the Cayuaga Reservation Lands W. and Marcellus E. and 9 miles E. of the ferry on Cayuaga Lake. By the state census of 1796, 213 of the inhabitants are electors.—*ib.*

AUTENIQUA, a large and beautiful country in Africa, lying to the east of the Cape of Good Hope, and inhabited, part of it, by Dutch colonists. The word *Auteniqua* signifies, in the Hottentot language, "a man loaded with honey;" a name which is not improperly given to the country, since, as you enter it from the Cape, you cannot proceed a step without seeing a thousand swarms of bees. The flowers on which they feed spring up in myriads; and your attention is engaged, and your course suspended, by the mixed odours which exhale from them, by their colours and variety, and by the pure cool air which you breathe. Nature has made these enchanting regions like fairy land. The calyxes of all the flowers abound with excellent juices, from which the bees extract the honey that they every where deposit in hollow rocks and trees.

This country was visited in 1782 by M. Vaillant, who calls it the most delightful region in the universe;

Auteniqua. and says, that, as he approached it, he beheld, from the top of a very high mountain, an immense valley, adorned with agreeable hills, variegated in an infinite number of shapes, and extending in an undulating manner as far as the sea; whilst enamelled meads, and the most beautiful pastures, still added to the magnificent scene. It abounds with small rivulets, which, flowing down from the mountains, run into the sea through an hundred different channels. The water of these rivulets has the colour of Madeira wine, and a ferruginous taste; but our traveller did not examine whether this taste and colour proceed from their flowing through some mine in their passage, or from the roots and leaves of trees which they carry along with them.

The whole of Auteniqua, from the chain of mountains which divides it from the country of that race of Hottentots called *Gonaquas* to the sea, is inhabited by several planters, who rear a number of cattle, make butter, cut down timber, and collect honey; all of which they transport to the Cape: but it appears that they make not the most of their situation. "Can it be believed (says M. Vaillant), that the directors of the Company, for their own use, should order ships to be sent every year from Amsterdam, loaded with planks and boards of every kind, whilst in this country there are immense forests, and the most beautiful trees in the world? This absurdity, however, is not at all astonishing. The Company gratuitously furnishes the governor and all the officers with whatever wood they have occasion for; and it is delivered to them at their houses without any expence. The governor therefore has no *personal* interest to extend his views to this part of the administration, and to abolish an abuse so prejudicial to the colony."

But the colonists themselves must be a very indolent and stupid kind of people; since, if our traveller deserves credit, they neglect advantages with which the personal interest of the governor cannot possibly interfere. "I was filled with indignation (says M. Vaillant) to see people, who have wood within their reach, employ it in commerce, and not have the courage to build for themselves habitable houses. They live in wretched hovels, constructed of wicker-work, daubed over with clay; the skin of a buffalo, fixed at the four corners to as many stakes, serves them for a bed; and the door, which is at the same time a window, is shut by a mat; while two or three mutilated chairs, a few pieces of plank, a kind of table, and a pitiful box of two feet square, form all the furniture of these colonial habitations. Thus is the picture of the most profound misery contrasted with the charms of this terrestial paradise; for the beauties of these regions extend even beyond Auteniqua. The people, however, though their houses be bad, live well. They have game and salt-water fish in abundance; and enjoy exclusively, over all the other cantons of these colonies, the advantage of having, for the whole year without interruption, vegetables of every kind in their gardens. For this they are indebted to the excellence of the soil, and to its being naturally watered by small streams, which cross each other in a thousand different directions, and, as one may say, lay the four seasons under contribution to fertilize Auteniqua. These streams, which frequently overflow their banks, but never dry up, proceed from a cause well known; the high mountains towards the east, which are covered with forests, stop the clouds and the fogs carried from the sea, and this occasions very abundant rains." Auteniqua.

In these mountainous regions, which, as well as the plain, our author comprehends under the denomination of *Auteniqua*, there are multitudes of elephants, buffaloes, panthers, hyenas, and antelopes of every species; and all these animals are hunted and killed by the natives, as well for food as for the protection of their flocks and herds from such of them as are beasts of prey. Our author has eaten the flesh of every one of them except the hyena; and declares, that the foot of an elephant, baked after the Hottentot manner, is one of the most delicious morsels that he ever tasted. He gives directions for hunting them all; but warns his readers from attacking elephants when he finds them in droves, for then, he says, they are invincible. He even thinks it exceedingly dangerous for one man, however well armed, to attack a single elephant in the plain. The buffalo he describes, contrary to most other travellers, as a timid animal, which never resists till his situation becomes desperate; and he thinks that there would be no difficulty in training him, if caught when a calf, to the yoke like the bullocks of Europe.

The kites and vultures of this country, our traveller represents as in the highest degree voracious and fierce, insomuch that it is hardly possible to fright them from their prey. He had on one occasion killed two buffaloes, which he ordered to be cut into very small pieces, that they might be more easily salted, and exposed afterwards to the air and the sun. His waggons, as well as the bushes and trees which surrounded him and his people, were loaded with the bloody fragments of these two animals, and they had begun their operation of salting: but on a sudden, while they were not expecting it, they found themselves attacked by flights of kites and vultures, which, without exhibiting the least symptoms of fear, perched in the midst of them. The kites were above all the most impudent. They seized upon the morsels of flesh, and even contended furiously with his people. "When they had each carried away (says he) a pretty large piece, they retired to some branch, at the distance of ten paces from us, and devoured it before our eyes. Though we fired our fusees they were not frightened, but returned incessantly to the charge; so that finding our powder wasted in vain, we resolved to keep them off with large poles until our provisions should be quite dry. This manœuvre, which for a long time harrassed my people, did not prevent us from being plundered without mercy; but had we not employed it, nothing would have remained to us of our two buffaloes."

This battle with the kites took place on the confines of the Dutch settlements; but when M. Vaillant had with difficulty passed over the mountains which bound them, the prospects became more magnificent, the soil seemed to be more fruitful and rich, nature appeared to be more majestic and grand, and the lofty mountains presented on all sides more charming and delightful points of view than any that he had ever before met with. These scenes, contrasted with the dry and parched fields of the Cape, made him exclaim, he says, in ecstacy, "What! shall these superb regions be eternally inhabited by tygers and lions? What speculator, with the sordid view only of establishing a kind of centre for commerce, Auteniqua. commerce, could have preferred the ſtormy Table Bay to the numberleſs roads and commodious harbours which are to be found on the eaſtern coaſts of Africa? Thus (continues he) was I reflecting within myſelf, whilſt I was climbing the mountain, and forming vain wiſhes for the conqueſt of this beautiful country, which the indolent policy of the European nations will perhaps never gratify."

If his deſcription of its beauties and fertility be not greatly exaggerated, it is indeed wonderful that either the Dutch or ſome other maritime power of Europe has not long ago taken poſſeſſion of it. After he had paſſed the mountain, one could not, he ſays, chooſe a more agreeable or advantageous ſpot than that upon which he then was for eſtabliſhing a thriving colony. The ſea advances through an opening of about a thouſand paces in breadth, and penetrates into the country to the diſtance of more than two leagues and a half. The baſon which it forms is more than a league in extent (he does not ſay whether in breadth or in circumference); and the whole coaſt, both on the right and the left, is bordered with rocks, which intercept all communication with it. The land is watered by limpid and refreſhing ſtreams, which flow down on all ſides from the eaſtern mountains; and theſe mountains, crowned with majeſtic woods, extending as far as the baſon, and winding round it with a number of ſinuoſities, exhibit a hundred groves, which are naturally variegated, and each more agreeable than another.

The author proceeding forwards about two days journey, arrived at a bay known to navigators by the name of the Bay of *Agoa*, but called by the coloniſts *Blettenberg's* Bay, from its having been viſited ſome time before by a Governor Blettenberg, who ordered his name, together with the year and day of his arrival, to be engraven on a ſtone column. This bay is a little beyond the limits of the country called Auteniqua; but it is not foreign from the purpoſe of this article to inſert in this place our traveller's account of it, and of the country around it.

The bay itſelf, he ſays, is very ſpacious, and has a ſufficient depth of water for the largeſt veſſels. The anchoring ground is ſure, and boats can ſail to a beautiful part of the ſhore, which is not confined by the rocks, as they are all there detached from one another. By advancing a league along the coaſt, the crews would arrive at the mouth of a conſiderable river called the *Queur-Boom*, where they would find water. Refreſhments might be procured from the inhabitants of the environs; and the bay would ſupply them with excellent fiſh, with which it abounds.

This bay is one of thoſe places where government might eſtabliſh warehouſes and repoſitories for timber; and it is for this reaſon that we have introduced it to notice in this article. The foreſts around it, ſays M. Vaillant, are everywhere magnificent, and the trees could be more eaſily cut down than anywhere elſe; for it is not to ſteep mountains that one muſt go for wood, as at Auteniqua; it is here ready at hand; and during the fine monſoon might be tranſported to the Cape with little trouble and no riſk. The inexhauſtible and fertile lands in the neighbourhood of the bay, if once cultivated, would produce abundant crops, and draw together a great number of intelligent planters, on account of the ready communication which they would have with the Cape. In a word, the Company, continues he, have nothing to do ſo much for their own intereſt as to form here a proper eſtabliſhment. To the general profits of ſuch an inſtitution, would be added thoſe of individuals, which could not fail to be of great importance. They might, for example, cut down a certain tree called *ſtinking wood*, and export it to Europe, where it would undoubtedly be ſoon preferred to mahogany and every other kind of wood employed by cabinet makers.

Auteniqua ‖ Automaton.

The Hottentots, who in ſcattered *kraals* inhabit this delightful country, our author deſcribes as a faithful, gentle, and rather timid race. He affirms, that they have no religious impreſſions whatever, nor any notion of ſuperior powers who govern the world. But this, if not a wilful falſehood dictated by the philoſophy of France, is probably a miſtake ariſing from his ſcanty knowledge of their language, and total ignorance of the meaning of their religious ceremonies. His great maſter, as well as the maſter of his ſect, *Lucretius*, might have taught him, that fear, if not a better principle, will generate the notion of ſuperior beings in the minds of ſavages; and from fear, by his own account, the inhabitants of Auteniqua are far from being free. He likewiſe affirms, and ſeems to conſider it as much to their credit, that this race of gentle beings, ſo far from being a prey to the paſſion of jealouſy (as other travellers have repreſented the Hottentots in general), are ſo obliging, as to lend their wives to travellers who viſit them, and that they actually accommodated his Hottentots in this way. Auteniqua, as laid down in M. Vaillant's map, lies between 33° 30 and 34° 50′ of ſouth latitude, and between 20° and 23° 40′ of eaſt longitude; and his rout through the country was from ſouth-weſt to north-eaſt, or nearly ſo.

AUTOMATON. Under this title and that of ANDROIDES full credit was allowed in the *Encyclopædia* to the ſtory of M. de Kempell's mechanical *cheſs-player*, and a detail at ſome length was given of the feats of that figure, as well as of ſome other ſurpriſing *automata*. No man more readily admits the powers of the ſkilful mechanician than the writer of this ſhort article; but having many years ago detected the impoſition which was practiſed on the public in ſome parts of Scotland by a circumferaneous mountebank, who exhibited a figure apparently capable of writing a certain number of words, he has ever ſince ſuſpected impoſture in all automata which appear to have the power of varying their motions according to circumſtances. With reſpect to the *cheſs-player*, there is now ſufficient evidence that his ſuſpicions were well founded.

In the deſcription of this figure (*Encycl.* Vol. I. p. 787.), "it is ſaid, that the automaton could not play unleſs M. de Kempell or his ſubſtitute was near it to direct its moves. A ſmall box during the game was frequently conſulted by the exhibiter; and herein conſiſted the ſecret, which he ſaid he could in a moment communicate." The ſecret was indeed ſimple: "A well taught boy, very thin and ſmall of his age, was concealed in this box almoſt immediately under the cheſs-board, and agitated the whole machine." This we learn from Thomas Collinſon, Eſq. who was let into the ſecret at Dreſden by a gentleman of rank and talents, named *Joſeph Freidrick Freyhere*, by whom the *vitality* and *ſoul* of the cheſs-playing figure had ſome time before been completely discovered. Mr Collinson, finding that Dr Hutton had given the same credit with us to the reality of mechanical chess-playing, undeceived his friend, by communicating the discovery of Freyhere in a letter, which the Doctor has with great propriety published in the *Addenda* to his Mathematical Dictionary. Mr Collinson adds, and we doubt not with truth, that, "even after this abatement of its being strictly an automaton, much ingenuity remains to the contriver." This was in some degree true of the mechanism of the writing figure, of which the compiler of this article detected the bungling imposture of the two exhibiters. The figure itself, with all the principles of its motion, was very ingeniously constructed; but the two men who exhibited it were ignorant and aukward, and could not conceal from a scrutinizing eye, that the automaton wrote sometimes well and sometimes ill, and never wrote at all when they were both present to the company. It was by insisting upon seeing them both together, and threatening to expose the cheat to the whole town, that the present writer prevailed upon him who appeared to be the principal exhibiter, to confess in private that his companion was concealed behind a screen, and to show how, from thence, he directed the movements of the figure.

Conjugate AXIS, or *Second Axis*, in the ellipse and hyperbola, is the diameter passing through the centre, and perpendicular to the transverse axis; and is the shortest of all the conjugate diameters.

Transverse Axis, in the ellipse and hyperbola, is the diameter passing through the two foci and the two principal vertices of the figure. In the hyperbola it is the shortest diameter, but in the ellipse it is the longest.

B.

BAAL's *River* and *Bay*, in West Greenland, lie between Bear Sound on the S. E. and Delft's Point on the N. W. and opposite the mouth of Hudson's Strait.—*Morse*.

BABAHOYO, a village and custom house on Guayaquil River, in Peru, being the landing place from the city of Guayaquil. Here the merchandize from Peru and Terra Firma, and their respective provinces, are landed.—*ib*.

BABOPAS, a town in the interior parts of New Albion, eastward of the long range of mountains which extend northward from the head of the peninsula of California. N. lat. 37. 45. W. long. 114. 25. —*ib*.

BAFFIN's *Bay*, is the largest and most northern gulf, or bay, that has yet been discovered in N. America; and lies between the 70th and 80th degrees of N. lat. It opens into the Atlantic ocean through Baffin's and Davis's straits, between Cape Chidley on the Labrador coast, and Cape Farewell on that of West Greenland; both of which are in about the 60th degree of N. lat. It abounds with whales; and on the S. W. side of Davis's straits has a communication with Hudson's Bay, through a cluster of islands. It was discovered by the navigator whose name it bears, in the year 1662. Some maps shew a communication with Hudson's Bay, in the 70th degree of N. lat. and in the 70th of W. long.—*ib*.

BAHAMA *Islands*, (See Encycl.) The first discovery of the New World, by Columbus, began October 11, 1492, at Guanahani, or Cats Island, one of the Bahamas. They were then full of people; who were simple, mild and lived happy in the midst of plenty. These unfortunate people were transported to the mines of St Domingo, after the cruel Spaniards had exterminated the numerous inhabitants of that large island; 14 years after the discovery of these islands, not one person remained in any of the Bahamas. At this time Charles II. granted the Bahamas to the proprietors of Carolina. They sent several governors, and built the town of Nassau, which is now the seat of government in the Island of Providence. The island of Providence afterwards became an harbour for pirates, who, for a long time, infested the American navigation. In 1718, Capt. Woods Rogers was sent out to dislodge the pirates, and form a settlement. This the captain effected; and the islands have been improving since by a slow progress. In time of war, the people gain considerably by the prizes condemned there; and in the course of the present war between Great-Britain and France, numbers of American vessels, carrying provisions and stores to French ports, have been carried in and condemned; and at all times they profit by the wrecks which are frequent in this labyrinth of rocks and shoals. The Spaniards and Americans captured these islands during the last war; but they were retaken April 7, 1783. The Bahamas are said to be 500 in number; some of them only rocks, others very low and narrow, or little spots of land on a level with the water's edge; but 12 of them are large and fertile, some indeed rocky and barren. Five of them only are inhabited, viz. *Providence*, *Harbor*, *Eleuthera*, *Cat*, and *Exuma*; *Turk*'s islands have about 500 men in the salt season, but at other times half of them return to Bermuda.

The principal island which has given its name to the whole cluster is *Great Bahama*, in the *Northern Bank*, called the *Little Bank of Bahama*, whose situation is E. and W. about 20 leagues from the coast of Florida. At a little distance to the E. is *Lucayoneque*, of nearly the same size, whose situation is N. and S. To the N. of both is *Lucayo*, which lies E. and W. A channel

channel of 8 or 10 leagues feparates the Little Bank, from the Great Bank, in which is *Providence I.* with the great ifland of *Alabafter*, which has *Harbor I.* on the N. Cape. *Andros* iflands are on the S. W. of Providence, which take up a fpace of 30 leagues long and 5 broad. Towards the S. E. are *Stocking*, *Exuma*, and *Yuma*, or Long Ifland. *Guanahani*, or Cats I. the firft difcovered in America, lies E. of the Great Bank, and is feparated from it by Exuma Sound.

The climate of thefe iflands is temperate and the air healthy. On the coafts is found ambergrife; and the inhabitants catch great quantities of green turtle. The only article cultivated for exportation is cotton; of which the medium export is 1,500 bags of 2 cwt. each. In 1787, there were 4,500 acres in cotton. In 1785, 1786, and 1787, which were favorable years, each acre produced about 112lb. It is very liable to be deftroyed by the worms; between Sept. and March, 1788, no lefs than 280 tons were deftroyed. Thefe iflands alfo produce a great quantity of dying woods, and fome lignumvitæ and mahogany; and lie between 22. and 27. N. lat. and 73. and 81. W. long. In 1773, there were 2052 white, and 2241 black, inhabitants; but of late years there has been a confiderable emigration from North America, fo that the precife number cannot be given.—*ib.*

BAHIA DE CHETUMEL, called by the Britifh Hanover Bay, lies on the E. fide of the peninfula of Yucatan in the fea of Honduras, and into which falls Honde River. It has the Logwood Country on the S. At its mouth are two large iflands and a number of iflots. The largeft ifland is Ambergrife Key, which runs along the mouth of the bay, and is 70 miles long.—*ib.*

BAHRDT (Dr Carl Friedirich) was fo deeply concerned in a combination of philofophers formed, as they faid, for the advancement of fcience and virtue, that an account of his life muft be interefting, if it were only to fhow the effects of this philofophic culture on his own morals. We truft therefore that our readers will be pleafed, perhaps improved, by the following narrative, taken from documents the moft authentic, by a man * whofe communications on other fubjects do credit to this volume.

* See Profeffor Robifon of Edinburgh's *Proofs of a Confpiracy againft all the Religions and Governments of Europe.*

Carl Friedirich Bahrdt was, in 1741, born at Leipfig, where his father, then a parifh minifter, and afterwards profeffor of theology, died in 1775. It is natural to fuppofe that fuch a parent would be at due pains to inftil into the mind of his fon the principles of piety, virtue, and patriotifm, which is indeed a branch of virtue; but if fo, he lived to fee that his labour had been in vain. While yet at college, where the courfe of his ftudies was calculated to fit him for the important office of preaching the gofpel, the young man enlifted as a huffar in the Pruffian fervice; but being bought off, he returned to the univerfity, where, in 1761, he was admitted to the degree of M. A. Soon afterwards he became catechift in his father's church, was a popular preacher, and in 1765 publifhed fermons, and fome controverfial writings, which evinced that he poffeffed both learning and genius. Neither learning nor genius, however, nor both united, could attach him to the caufe of virtue, or make him obferve even the common rules of decorum; for immediately after this publication he began to indulge in conviviality, and to give fcope to his refentments in anonymous pafquinades, in the higheft degree bitter and offenfive. From the fhafts of his malice no perfon was fafe. Profeffors, magiftrates, and clergymen, had indeed his chief notice; but he condefcended occafionally to attack ftudents, and fpared not even his own comrades or his friends.

Whilft he was thus labouring to make enemies of all to whom he was known, unfortunately, for his own character, his temperament was what the atomical philofophers (who can explain every thing by ethers and vibrations) call fanguine; and he was, as he himfelf acknowledged, a paffionate admirer of the ladies. Coming home from his midnight revels, he frequently met in his way a young girl neatly dreffed in a rofe coloured filk jacket and train, and a coftly fable bonnet; and one evening, after having, as he fays, indulged freely in fome old Rhenifh, he faw her home to her lodgings. Some time after this interview, the miftrefs of the houfe (a Madam Godfchufky) came into his room, and faid that the poor *maiden* whom he had debauched was pregnant. This was a misfortune *which he could not help*; but as it would ruin his character if known, he gave to the old lady a bond for 200 dahlers (about L. 40 fterling), to be paid by inftalments of twenty-five, to keep the matter fecret. "The girl (he fays) was *fenfible* and *good*; and as her converfation, for which he had already paid, was agreeable, he did not difcontinue his acquaintance."

It could not be fuppofed that fuch vifits, by a clergyman, would pafs unobferved, however cautioufly made, in the midft of a town, of which the inhabitants had been the indifcriminate objects of his fatire; and he could hardly be furprifed when told by a friend, that one Bel, a magiftrate whom he had lampooned, was acquainted with the whole affair, and would bring it into a court of juftice, unlefs the bond was immediately retired.

This bond was the only evidence which could be produced againft Bahrdt, but it was fufficient to blaft his character in Leipfig, and muft therefore by any means be removed out of the way. To accomplifh this, however, was a matter of fome difficulty; for neither he nor his friend could raife the money. In this dilemma they fell upon a contrivance worthy of themfelves. They invited Madam Godfchufky to meet them in another houfe to receive the 200 dahlers due to her by Bahrdt; but when fhe was ufhered into the room, and found no perfon waiting for her but Bahrdt's friend, fhe could not be prevailed upon to produce the bond till the money fhould be put into her hands, together with a prefent to herfelf. The *Gentleman* tried to intimidate her. He drew his fword; fhowed her how men fence; made pufhes at the wall and then at her; but finding that fhe could not be frightened out of her fenfes, he threw away his fword, and endeavoured to take the bond from her by force. It was fome time before he prevailed; but at laft getting the paper out of her pocket, he tore it in pieces, opened the door of a clofet in which Bahrdt was concealed, and faid, "There, you b——; there is the honourable fellow whom you and your whore have bullied; but it is with me you have now to do, and you know that I can bring you to the gallows."

Bahrdt, from whofe memoirs of himfelf this ftory is taken, admits that there was a great fquabble on the occafion;

Bahrdt. occafion; but he went home, comforting himfelf with the belief that he fhould now have no farther trouble from Madam Godfchufky or her girl. He chanced, however, to be miftaken. The magiftrate Bel had fome how been made acquainted with this nefarious tranfaction, and brought it into court on the day that our hero was to make fome very reverend appearance at church. The cafe of Bahrdt was now hopelefs; for after fome unfuccefsful attempts of his poor father to fave him, he was obliged to give in his gown and band, and to quit Leipfig.

To a parent the public difgrace of a child is one of the fevereft calamities to which human nature is liable; but for this calamity the father of Bahrdt muft have been long prepared, as his fon appears to have been remarkably undutiful. Of this we have one memorable inftance recorded by himfelf. His father, he fays, was fevere, and his own temperament hafty, fo that he fometimes forgot himfelf. "One day (continues he) I laid a loaded piftol on the table, and told him that he fhould meet with that if he went on fo; but I was then only SEVENTEEN!"

On his being obliged to leave the place of his nativity, the friends of Bahrdt, and in particular Semler, an eminent theological writer, who had formed a very favourable opinion of his talents, were affiduous in their endeavours to procure an eftablifhment for him elfewhere; but his high opinion of himfelf, his impetuous and precipitant temper, and that fatirical habit which he had fo freely indulged in his outfet in life, made their endeavours long ineffectual. At laft he got a profefforfhip at Erlangen, then at Erfurth, and in 1771 at Gieffen. But in each of thefe places he was no fooner fettled than he got into difputes with his colleagues and with the eftablifhed church; for he was a ftrenuous partizan of the innovations then attempted to be made in the doctrines of Chriftianity. In his publications, which were generally anonymous, he did not truft to rational difcuffion alone, but had recourfe to ridicule and perfonal anecdotes, and indulged in the moft cutting farcafms and grofs fcurrility.

His love for convivial company continuing, his income was infufficient for the craving demand. Finding therefore that anecdote and flander always procured readers, and poffeffing a wonderful activity and facility in writing, he never ceafed from publifhing lampoons and fatires, in which he fpared neither friends nor foes. But it was impoffible to prevent thefe publications from being traced to their author; and his avowed theological writings being fuch as could not be fuffered in a profeffor of divinity, the hoft of enemies which he had been at fo much pains to raife againft himfelf, were furnifhed with fufficient grounds for fubjecting his conduct to legal cognizance; even the very ftudents at Gieffen were fhocked at fome of his liberties.

The confequence of all this was, that, after much wrangling in the church judicatories, he was juft about to be difmiffed from his profefforfhip, when he got an invitation to Marfchlins in Switzerland to fuperintend an academy.

To Marfchlins he went about the year 1776, and began his new career by forming the feminary after the model of an academy which had fome time before been fet up in the principality of Anhalt Deffau by one Bafedow, a man of talents and learning, who gave to it the appellation of PHILANTHROPINE. The plan of this academy was very different from thofe of the univerfities; for its author profeffed to confider languages, fciences, and the ornamental exercifes, as mere acceffories, his aim being to form the young mind to the love of mankind and of virtue, by a courfe of moral education certainly fpecious, and apparently unexceptionable. To make this novel inftitution the more extenfively ufeful, the rules by which the education was to be conducted were framed in fuch a manner as, it was thought, would remove from the minds of Catholics, Lutherans, and Calvinifts, all uneafinefs refpecting the faith of their children, as it related to thofe particular tenets which feparated them into different communions. It was even propofed to banifh from the philanthropine all *pofitive* religion whatever, and to inftruct the youth educated there in the principles only of natural, or, as it was called, *philofophical religion*.

This plan was peculiarly fuited to Bahrdt's tafte, becaufe it left him at liberty to introduce into his academy any fyftem of religious or irreligious opinions that he pleafed; a liberty of which he refolved to avail himfelf, and, though now a doctor in theology, to outftrip, in licentioufnefs, even the founder of the philanthropine, who was not in orders. By meditating on the workings of his own mind, he had by this time formed his theory of human nature, which was indeed very fimple. "The leading propenfities of the human mind (he fays) are three; inftinctive liberty, inftinctive activity, and inftinctive love." By thefe expreffions we fuppofe he means, "innate *love* of liberty, inftinct prompting to action, and the fexual appetite:" and he immediately adds, that "if a man is obftructed in the gratification of any of thefe propenfities, he fuffers an injury. The bufinefs therefore of a good education is to teach us how they are to be gratified in the higheft degree."

That fuch an education would be approved of by the uncorrupted natives of Switzerland was hardly to be expected; and Bahrdt foon found his fituation at Marfchlins as uncomfortable as it had been at Gieffen. "The Grifons (he fays) were a ftrong inftance of the immenfe importance of education. They knew nothing but their handicrafts; and their minds were as coarfe as their perfons." He quarrelled with them all, and was obliged to abfcond after lying fome time in prifon.

From Marfchlins he went to Durkheim, a town in the palatinate, where his father had been minifter, and where his literary talents were well known. After fome little time he got an affociation formed for erecting and fupporting a *Philanthropine* or houfe of education. A large fund was collected; and he was enabled to travel into Holland and England to engage pupils, and was furnifhed with proper recommendations.

In London he gained the friendfhip of a clergyman, whom he reprefents as a perfon in the higheft degree accomplifhed. "With found judgment (fays Bahrdt), great genius, and correct tafte, he was perfectly a man of the world. He was my friend, and the only perfon who warmly interefted himfelf for my inftitution. To his earneft and repeated recommendations I owe all the pupils that I got in England, and many moft refpectable connections; for he was univerfally efteemed as a man of learning and of the moft unblemifhed character. He was my friend, my conductor, and I may fay my preferver;

Bahrdt. preserver; for when I had not bread for two days, he took me to his houfe, and fupplied all my wants."

For fo much kindnefs the reader doubtlefs fuppofes that the heart of Bahrdt overflowed with gratitude; but if fuch be his opinion, he is a ftranger to the principles of thofe who have on the continent of Europe affociated for the purpofe of enlightening the world. This amiable man, whofe character is here fo juftly drawn, was afterwards depicted by the monfter whom he had faved from perifhing by hunger, as a wretch loft to all fenfe of fhame and decency, as an apoftate from the Chriftian faith, and as a notorious frequenter of the London brothels! Fortunately he was able to vindicate his character completely from this flanderous abufe, and to convict Bahrdt of having publifhed what *could not poffibly be true*.

This ungrateful liar returned from England, and carried into execution his plan of the Philanthropine. The caftle of Count Leining Hartzburgh at Heidefheim, having gardens, park, and every handfome accommodation, had been fitted up for it; and in 1778 it was confecrated by a folemn religious feftival. But his old misfortunes purfued him. He had indeed no colleagues with whom he could quarrel; but his *avowed* publications became every day more obnoxious; and when any of his *anonymous* pieces had a great run, he could not fo far ftifle his vanity as to conceal that he was the author. Of thefe pieces fome were fhocking to decency, and others fo horribly injurious to the characters of the moft refpectable men in the ftate, that he was continually under the correction of the courts of juftice. It was hardly poffible for a man of letters to be in his company, and not fuffer by it; for it was his conftant practice to attribute every ftep which he took towards atheifm, to the force of the arguments urged by fome of his friends.

To be his friend, or to obtain his applaufe, was indeed fo great a misfortune, that when the reader fees any perfon celebrated by Dr Bahrdt, in the beginning of a book, for found fenfe, profound judgment, accurate reafoning, or praifed for acts of friendfhip to himfelf, he may be affured, that before the clofe of the book this man fhall be reprefented as having in private converfation convinced the author, that fome doctrine, cherifhed and venerated by all Chriftians, is a piece of knavifh fuperftition.

Dr Bahrdt had married, while at Gieffen, a woman with a fmall fortune: but fuch a ftranger was he to the delicacies of wedded love, fo loft indeed to all fenfe of decency, that he contrived one day to entice his wife *naked* into the bath in the garden of his Philanthropine, where, in the water, he, being alfo *naked*, toyed with her in the fight of all his pupils. It was his boaft that he held his opinions independent of all mankind, and was indifferent whether they procured him praife or reproach: but it appears from this fact, that he was, equally regardlefs of the praife or cenfure which might be attached to his actions; for furely the groffeft hog that ever before him battened in the Epicurean fty would not have prefented fuch an exhibition to boys.

The confequence of all this was, that he was obliged to fly from Heidefheim, leaving his fureties in the Philanthropine to pay about 14,000 dahlers, befides debts without number to his friends. He was imprifoned at Dienheim; but being foon releafed, he fettled at Halle, where he funk to be the keeper of a tavern and billiard-table. His houfe became of courfe the refort and the bane of the ftudents in the univerfity, and he was obliged to leave the city. He had fome how got money fufficient to purchafe a little vineyard, pleafantly fituated in the neighbourhood. This he fitted up with every accommodation that could invite the ftudents, and called it *Bahrdt's Ruhe* (Bahrdt's repofe) where he lived for two years, directing the operations of a fecret fociety called the GERMAN UNION, FOR ROOTING OUT SUPERSTITION AND PREJUDICES, AND FOR ADVANCING TRUE CHRISTIANITY.

With Bahrdt's qualifications for advancing the interefts of genuine Chriftianity, the Chriftian reader is already fufficiently acquainted: but he will not wonder at his appointment to this high office, when he is informed that the GERMAN UNION is nothing more than a fpawn of the fecret fociety of *Illuminati* (fee ILLUMINATI in this Supplement); and that its object is to abolifh the religion of the gofpel, and to teach in its ftead the fatalifm of the Stoics. With this view Chriftianity is confidered in the UNION as a myftical fociety, and its Divine Founder as the grand mafter of a lodge! The apoftles Peter, James, John, and Andrew, were the ELECT, brethren of the *third* degree, and initiated into all the myfteries. The remaining apoftles were only of the *fecond* degree; and the feventy-two, of the *firft*: a degree into which ordinary Chriftians may be admitted, and prepared for farther advancement. The great myftery is, that J—— C—— was a NATURALIST, and taught the doctrine of a fupreme mind, the fpectator but not the governor of the world.

To propagate thefe impious and abfurd notions, Bahrdt publifhed many books of the moft antichriftian tendency, and fome of them calculated to make their readers fhake off all moral obligation. But the labours of the fociety were not confined to religion: it inculcated on its members the moft dangerous maxims of civil conduct: for, as we learn from Bahrdt himfelf, the objects at which the Union aimed were—*Advancement of fcience—a general intereft and concern for arts and learning—excitement of talents—check of fcribbling—good education*—LIBERTY—EQUALITY—*hofpitality*—DELIVERY OF MANY FROM MISFORTUNES—*union of the learned—and at laft—perhaps—Amen.*

What the meaning of this enigmatical conclufion is we can only guefs; and we agree with the real philofopher from whom we have taken this account, that our conjectures cannot be favourable. Bahrdt was a villain, and could be affociated only with villains, whofe affairs he managed with the help of an old man, who lived at bed and board in his houfe for about fix fhillings a week, and difcharged the office of fecretary to the UNION.

When he had toiled in this caufe near two years, fome of the fecrets of the Union tranfpired; his former conduct and his conftant imprudence made him fufpected; his affociated friends lodged informations againft him; his papers were feized; and he himfelf was fent to prifon, firft at Halle and then at Magdeburg. After fomething more than a year's confinement, he was fet at liberty, and returned to his *Ruhe*, not, alas! to live at eafe, or to exhibit fymptoms of repentance, but to lie down on a fick-bed, where, after many months fuffering of increafing pain, he died on the 23d of April 1793, 1793, the moſt wretched and loathſome victim of unbridled ſenſuality.

Such were the fruits of the German Union, and of that illumination which was to refine the heart of man, and bring to maturity the ſeeds of native virtue, which are choaked in the heart by ſuperſtition and deſpotiſm. Dr Bahrdt affected to be the enlightner and reformer of the world; and affirmed, that all the evils of life originated from deſpotiſm and ſuperſtition. "In vain (ſays he) do we complain of the inefficacy of religion. All poſitive religion is founded on injuſtice. No prince has a right to preſcribe or ſanction any ſuch ſyſtem; nor would he do it, were not the prieſts the firmeſt pillars of his tyranny, and ſuperſtition the ſtrongeſt fetters for his ſubjects. He dares not ſhow Religion as ſhe is, pure and undefiled—ſhe would charm the eyes and the hearts of mankind, would immediately produce true morality, would open the eyes of free born man, would teach him what are his rights and who are his oppreſſors, and princes would vaniſh from the face of the earth."

Therefore, without troubling ourſelves with the truth or falſehood of his religion of nature, and aſſuming it as an indiſputable point, that Dr Bahrdt has ſeen it in this natural and ſo effective purity, it is ſurely a very pertinent queſtion, "Whether has the ſight produced on his mind an effect ſo far ſuperior to the acknowledged faintneſs of the impreſſion of Chriſtianity on the bulk of mankind, that it will be prudent to adopt the plan of the German Union, and at once put an end to the diviſions which ſo unfortunately alienate the minds of profeſſing Chriſtians from each other?" The account here given of Dr Bahrdt's life ſeems to decide the queſtion.

But it will be ſaid that we have only related ſo many inſtances of the quarrels of prieſts and their ſlaviſh adherents with Dr Bahrdt. Let us view him in his ordinary conduct, not as the champion and martyr of illumination, but as an ordinary citizen, a huſband, a father, a friend, a teacher of youth, a clergyman.

When Dr Bahrdt was a pariſh-miniſter, and preſident of ſome inferior eccleſiaſtical diſtrict, he was empowered to take off the cenſures of the church from a young woman who had borne a baſtard child. By violence he again reduced her to the ſame condition, and eſcaped cenſure by the poor girl's dying of a fever before her pregnancy was far advanced, or even legally documented. On the night of the ſolemn farce of conſecrating his Philanthropine, he debauched the maid-ſervant, who bore twins, and gave him up for the father. The thing was not judicially proved, but was afterwards made ſufficiently evident by letters found among his papers, and publiſhed by one of his friends in the UNION. Having ſupported theſe infants, in a pitiful manner, for little more than a year, he cauſed them to be taken away from their mother, during night, ſome time in the month of February 1780; and they were found expoſed, the one at Uſſtein, and the other at Worms, many miles diſtant from each other, and almoſt frozen to death.

So much for the purity of his morals and his religion, as he appears in the character of a father and of a clergyman. His *decency* as a huſband, and his gratitude to his friend, we have already ſeen; and we ſhall now ſee his kindneſs and fidelity. After waſting the greateſt part of his wife's little fortune, he was ſo provoked becauſe her brother would not give him up the remainder, amounting to about L. 110, that he ever afterwards treated her with the greateſt cruelty, and exhibited her to contempt and ridicule in two infamous novels. At Halle he brought a miſtreſs into the houſe, and committed to her the care of his family, confining his wife and daughter to their own apartment; and the laſt thing which he did was to ſend for a bookſeller, who had publiſhed ſome of his vileſt pieces, and, without a thought of his injured wife, recommend his ſtrumpet and her children to his protection.

"Think not, indignant reader (ſays Arbuthnot), that this man's life is uſeleſs to mortals." It ſhows in a ſtrong light the falſity of all his declamations in favour of his ſo much praiſed natural religion and univerſal kindneſs and humanity. No man of the party writes with more perſuaſive energy, and, though his petulance and precipitant ſelf-conceit lead him frequently aſtray, no man has occaſionally put all the arguments of theſe philoſophers in a clearer light; yet we ſee that all is falſe and hollow. He is a vile hypocrite, and the real aim of all his writings is to make money, by foſtering the ſenſual propenſities of human nature, although he ſees and feels that the completion of the plan of the German Union would be an event more deſtructive and lamentable than any that can be pointed out in the annals of ſuperſtition. We will not ſay that all the partiſans of illumination are hogs of the ſty of Epicurus like this wretch; and it would be extremely unjuſt to conſider his vices as the effects of his illumination. He was ſenſual, ungrateful, and profane, before he was admitted into the order of the *Illuminati;* but had the views of that order been ſuch as were held out to the world at large, its ſagacious founder would not have initiated a wretch ſo notoriouſly profligate as Dr Bahrdt. Their views, however, being to govern mankind thro' the medium of their ſenſual appetites, and to reign in hell, rather than ſerve in heaven, they could not have employed a better inſtrument. Dr Bahrdt was a true diſciple of illumination; and though his torch was made of the coarſeſt materials, and ſerved only to diſcover ſights of woe, the horrid glare darted into every corner, rouſing hundreds of filthy vermin, and directing their flight to the rotten carrion, where they could beſt depoſit their poiſon and their eggs. Whilſt the more decent members of the Union laboured to pervert the refined part of mankind by declamations on the rights of man and the bleſſings of liberty, Bahrdt addreſſed himſelf to readers of all deſcriptions, and aſſailed at once the imagination and the appetites. He taught them, that religion is an impoſture; that morality is convenience; and, with blaſphemy peculiar to himſelf, that he and his order, by their licentious doctrines, were to *complete the plan and aim of* J —— C ——.

BAILLY (Jean-Sylvian), who made ſuch a figure during the firſt years of the French revolution, was born at Paris on the 15th of September 1736, of a family which had been diſtinguiſhed painters during four ſucceſſive generations. He was bred to the ſame profeſſion, but ſhowed an early taſte for poetry and the belles lettres. Chancing, however, to become acquainted with the geometer La Caille, this circumſtance decided his genius, and he thenceforth devoted himſelf to the cultivation of ſcience. He calculated the orbit of the comet of 1759; and on the 29th of January 1763 was received

Bailly.

received into the Academy of Sciences. In that year he publiſhed an uſeful and laborious compilation, being the reduction of the obſervations made by La Caille in 1760 and 1761, on the zodiacal ſtars. He likewiſe began to conſider the theory of Jupiter's ſatellites, and, in the competition for this prize queſtion of 1764, had a formidable rival in La Grange, who already promiſed to become the firſt mathematician in Europe. The reſults of his inveſtigations were collected into a treatiſe publiſhed in 1766, containing alſo the hiſtory of that part of aſtronomy. In 1771 he gave a moſt curious and important memoir on the light of the ſatellites, and introduced a degree of accuracy till then unknown in the obſervations of their ellipſes.

His ſtudies were not confined to the abſtract ſciences; for he cultivated letters with ſucceſs. His elogies of Charles V. of Corneille, of Leibnitz, of Moliere, and afterwards thoſe of Cook, La Caille, and Greſſet, were much admired. His eloquence pointed him out as a proper perſon to fill the charge, vacant in 1771, of ſecretary to the Academy of Sciences; and, under the patronage of Buffon, he ſtood candidate for that enviable place. He failed: but it was the high birth and promiſing talents of the young Condorcet, joined to the active influence of D'Alembert, that carried the prize.

In 1775 appeared the firſt volume of the Hiſtory of Aſtronomy, which indeed ſtrews the path of ſcience with flowers, and in every reſpect is a moſt valuable work—full of animated deſcription, of luminous narrative, and intereſting detail. His very peculiar ideas concerning the early ſtate of Upper Aſia gave riſe to an ingenious correſpondence and diſcuſſion with the veteran philoſopher Voltaire, the ſubſtance of which ſoon appeared in two volumes, intitled, "Letters on the Origin of Sciences," and "Letters on the Atlantide of Plato." If imagination ſhone forth in theſe eſſays, erudition was no leſs conſpicuous in a great work compoſed in the year 1781 and 1782, on the fables and religious creeds of antiquity; which ſtill exiſts in manuſcript, and the publication of which would aſſuredly extend the fame of its author and gratify the learned world. His opinions on ſome points happening to coincide with the theories of Buffon, he contracted with that celebrated naturaliſt a cloſe friendſhip, which was diſſolved by Bailly's uncourtly oppoſition to the election of the Abbé Maury into the *Academie Françaiſe*. Of that academy he had been choſen ſecretary in 1784; and he was admitted, in the following year, into the Academy of Inſcriptions and Belles Lettres; the only inſtance, ſince Fontenelle, of the ſame perſon being at once a member of all the three academies. In the meantime, the other volumes of the Hiſtory of Aſtronomy ſucceſſively appeared, and that capital work was completed in 1787 by the Hiſtory of the Indian and Oriental Aſtronomy; a production of ſingular acuteneſs, reſearch, and nice calculation.

In 1784 he made an elegant report to the Academy of Sciences on the animal magnetiſm of Meſmer; and in 1786 another report, which diſplays the judgment and humanity of its author, on a project for a new *hotel dieu* or infirmary.

We now approach the eventful period which ſummoned Bailly from his retirement, to enter on a political career, that was full of difficulty and danger, and for which his habits and ſtudies appear not to have fitted him. He had ſeen, as others ſaw, the defects of the old government of France. His heart panted for civil and eccleſiaſtical liberty; but unfortunately, like many other philoſophers both in his own country and in this, he had formed notions of that bleſſing which experience ſhould have taught him can never be realiſed among beings ſo imperfect as the bulk of mankind. When the ſtates-general were ſummoned to meet, he was on the 26th of April 1789 nominated ſecretary by the electors of Paris, and then appointed one of the deputies. He was choſen preſident of the *Tiers Etat;* and when that chamber was conſtituted the National Aſſembly, he continued in the chair, and concurred in all the levelling decrees which laid the foundation of the preſent miſery of his country, as well as of moſt other countries of Europe.

After the taking of the Baſtile, when the king was removed to Paris on the 15th of July, Bailly was called by public acclamation to the head of that city, with the title of *Mayor*. In his ſeveral functions he acted with integrity, courage, and moderation. He reached the ſummit of glory:—but how mutable, alas! is human grandeur! That middle courſe of conduct, the *aurea mediocritas*, at which virtue aims, is fitted to pleaſe neither of the contending parties in the midſt of revolutions: and ſuch proved the ruin of Bailly. His popularity began to decline, and was at length changed into inveterate enmity by an unfortunate accident. On the 17th of July 1791, the populace having collected tumultuouſly to demand the abolition of monarchy, Bailly was ordered by the National Aſſembly to diſperſe the mob. He was obliged to proceed to the Champ-de-Mars at the riſk of his life; and, in ſpite of all his exertions and forbearance, ſome ſhots were fired by the ſoldiery. It was no longer deſirable to hold his perilous charge, and on the 16th of November following he gave way to the aſcending reputation of Petion. The impaired ſtate of his health, too, rendered it expedient to retire from the focus of turbulence. He ſpent the year 1792 and part of 1793 in travelling through different provinces of France. During this period he wrote memoirs of the events which he had witneſſed, and in which he had often been a principal actor. Theſe come down only to the 2d of October 1789, but would make a large quarto volume; and La Lande, from whoſe *Eloge de Bailly* this article is taken, gives us hopes, that the manuſcript will be publiſhed. He was adviſed by his friends to withdraw from France, but he choſe rather, like Socrates, to ſubmit to the injuſtice and ingratitude of his country. At the nod of a vulgar tyrant he was arreſted, ſummarily condemned by a ſanguinary tribunal, and on the 15th of November 1793 was delivered over to appeaſe the vengeance of an incenſed and indiſcriminate populace. His ſufferings were ſtudiouſly protracted, but he bore them with the calmneſs and magnanimity of a ſage. Nature recoils at the recital of ſuch barbarities.

In 1787 M. Bailly married the widow of one who had been during 25 years his intimate friend; a woman more qualified by her age and condition to inſpire reſpect than the paſſion of love. He was tall in his perſon, of a ſerious deportment, and joined firmneſs to ſenſibility. Never did philoſopher diſtinguiſh himſelf in ſo many different lines, nor acquire ſuch deſerved reputation in them all. His diſintereſtedneſs was pure and unaffected;

unaffected; and during his magistracy he spent a part of his fortune in relieving the wants of the poor. His virtue remained as untainted in his various public stations as in the sweet retirement of domestic life.

Such is the encomium passed upon this philosopher and statesman by no less a man than the celebrated astronomer M. DE LA LANDE; but to those who are not infected with the *mania* of freedom, it will doubtless appear greatly exaggerated. That M. Bailly was a man of eminence in the republic of letters, is known to all the learned of Europe; that in his political conduct he meant to promote the good of his country, it would certainly be presumptuous in us to deny; and that he suffered unjustly, is incontrovertible: But let it be remembered, that he suffered in a storm, which he exerted all his abilities to raise; and that he set an example of injustice, when he concurred in the degradation of the privileged orders, and in the violent confiscation of the property of the church.

BAIRDSTOWN, or *Beardstown*, in Nelson co. Kentucky, is a flourishing town, of 216 inhabitants, situated on the head waters of Salt river, 50 miles S. E. from Louisville, and nearly the same distance S. W. from Danville.—*Morse.*

BAKERSFIELD, a newly settled township in Franklin co. Vermont, formerly in Chittenden co. In 1790 it had only 13 inhabitants.—*ib.*

BAKERSTOWN, in Cumberland co. District of Maine, contains 1276 inhabitants; 162 miles N. E. from Boston.—*ib.*

BALD EAGLE, or *Warrior Mountains*, lie about 200 miles W. of Philadelphia, in Bedford co. Pennsylvania, and forms the western boundary of Bald Eagle Valley.

Bald Eagle is likewise the name of a river which runs a N. E. course 44 miles and falls into the W. branch of Susquehanna River. The head water of Huron River which falls into Lake Erie, is called Bald Eagle Creek.—*ib.*

BALD EAGLE VALLEY, or, as it is commonly called, *Sinking Spring Valley*, lies upon the frontiers of Bedford co. in Pennsylvania, about 200 miles W. from Philadelphia. It has on the E. a chain of high, rugged mountains, called the *Canoe Ridge*, and on the W. the *Bald Eagle*, or Warrior Mountains. This is a pleasant vale, of limestone bottom, 5 miles in extent where widest; and in the vicinity are great quantities of lead ore. It contained, in 1779, about 60 or 70 families, living in log-houses, who formed, in the space of 7 or 8 years, several valuable plantations, some of which are remarkably agreeable on account of their situation.

During the late war with Great Britain, lead was much wanted, and very difficult to be procured, which induced a company, under the promises of the state, to settle here, and establish a regular set of works. A fort of logs was erected for the protection of the miners; and a considerable quantity of ore was produced, from which lead enough was made, to give a competent idea of the real value of the mines in general. The danger of the situation, however, while an Indian war continued, occasioned the failure of the undertaking.

The lead ore was of many kinds; some in broad flakes, and others of the steely texture. Several regular shafts were sunk to a considerable depth; one of which was on the hill, upon which the fort was erected, and from which many large masses of ore were procured; but, not forming a regular vein, it was discontinued, and another opened about a mile from the fort, nearer to Frank's Town. Here the miners continued until they finally relinquished the business. When they first began, they found in the upper surface or vegetable earth, several hundred weight of cubic lead ore, clean and unmixed with any substance whatever, which continued as a clue, leading them down through the different strata of earth, marl, &c. until they came to the rock, which is here in general of the limestone kind.

Among other curiosities of this place, is that called *the Swallows*, which absorb several of the largest streams of the valley, and after conveying them several miles under ground, in a subterraneous course, return them again upon the surface. These subterraneous passages have given rise to the name, *Sinking Spring Valley*. Of these the most remarkable is called the *Arch Springs*, and run close upon the road from the town to the fort. It is a deep hollow, formed in the limestone-rock, about 30 feet wide, with a rude natural stone arch hanging over it, forming a passage for the water, which it throws out with some degree of violence, and in such plenty as to form a fine stream, which at length buries itself again in the bowels of the earth. Some of these pits are near 300 feet deep; the water at the bottom seems in rapid motion; and is apparently as black as ink; though it is as pure as the finest springs can produce. Many of these pits are placed along the course of this subterraneous river, which soon after takes an opportunity of an opening at a declivity of the ground, and keeps along the surface among the rocky hills for a few rods, then enters the mouth of a large cave, whose exterior aperture would be sufficient to admit a shallop with her sails full spread. In the inside it keeps from 18 to 20 feet wide. The roof declines as you advance, and a ledge of loose, rugged rocks, keeps in tolerable order, on one side, affording means to scramble along. In the midst of this cave is much timber, bodies of trees, branches, &c. which being lodged up to the roof of this passage, shews that the water is swelled up to the very top during freshes. This opening in the hill continues about 400 yards, when the cave widens, after you have got round a sudden turning (which prevents its being discovered till you are within it) into a spacious room, at the bottom of which is a vortex, the water that falls into it whirling round with amazing force; sticks, or even pieces of timber, are immediately absorbed, and carried out of sight, the water boiling up with excessive violence, which subsides by degrees, until the experiment is renewed.

From the top of the Bald Eagle Mountains is a fine prospect of those of the Alleghany, stretching along until they seem to meet the clouds. Much slate is found here, with strong signs of pit coal. Such as visit these parts must cross the Juniata river 3 or 4 times from Standing Stone or Huntington, to the fort; from which it is computed to be about 22 miles distance.—*ib.*

BALIOL (John), the competitor with Bruce for the crown of Scotland, was not (as he is said to have been

been in the *Encyclopædia)* the brother of King Alexander, but the great grandson of David Earl of Huntington, third son of King David I.

BALLISTIC Pendulum, an ingenious machine invented by Benjamin Robins, for ascertaining the velocity of military projectiles, and consequently the force of fired gunpowder. It consists of a large block of wood, annexed to the end of a strong iron stem, having a cross steel axis at the other end, placed horizontally, about which the whole vibrates together like the pendulum of a clock. The machine being at rest, a piece of ordnance is pointed straight towards the wooden block or ball of this pendulum, and then discharged: the consequence is this; the ball discharged from the gun strikes and enters the block, and causes the pendulum to vibrate more or less according to the velocity of the projectile or the force of the blow; and by observing the extent of the vibration, the force of that blow becomes known, or the greatest velocity with which the block is moved out of its place, and consequently the velocity of the projectile itself which struck the blow and urged the pendulum.

Hutton's Dictionary.

BALTIMORE *Co.* in Maryland, lies between Patapsco and Gunpowder rivers, the former dividing it from Ann Arundel co. on the S. and S. W. Gunpowder and Little Gunpowder separating it from Harford co. on the E. and N. E. It has Frederick co. on the W. and N. W. Pennsylvania on the N. and Chesapeak Bay on the S. E. Besides the rivers which bound it, and their branches, this county has Back and Middle rivers, between the two former, but they are rather arms of Chesapeak bay, than rivers. Back river, 4 or 5 miles E. of Patapsco, receives two small streams; the N. westernmost is called Herring Run. Middle river has little or no supply of fresh water. There are numerous iron works in this county; and it contains 25,434 inhabitants, including 5,877 slaves. Its chief town is Baltimore.—*Morse.*

Baltimore, (See Encycl.) From the head of Elk river at the head of the bay to Baltimore, is about 60 miles. The town is built around what is called the bason, reckoned one of the finest harbors in America. The water rises 5 or 6 feet at common tides. It is divided into what is called the town and Fell's Point, by a creek; over which are two bridges: but the houses extend, in an irregular manner, from the one to the other. At Fell's Point the water is deep enough for ships of burden, but small vessels only go up to the town.

The situation is low, and was formerly thought unhealthy, but, by its rapid increase, improvements have taken place, which have corrected the dampness of the air, and it is now judged to be tolerably healthy. In 1787, it contained 1955 dwelling houses; of which 1200 were in the town, and the rest at Fell's Point. It then contained 152 stores. The number of the inhabitants of the town and precincts, in 1791, were 13,503, including 1,255 slaves. The number of houses and inhabitants have been greatly increased since.

Before the emigration of the French people from Cape François and other islands, the houses had increased to 2,300. Those unfortunate people, flying from their merciless countrymen, who had burned and pillaged their cities and towns, and murdered their relations and friends, found here an hospitable asylum, after sufferings hardly paralleled in the annals of history.

Here are 9 places of public worship, which belong to Roman Catholics, German Calvinists and Lutherans, Episcopalians, Presbyterians, Baptists, Methodists, Quakers, and Nicolites, or New Quakers, who all live together in peace. It is inhabited by people from most parts of Europe. The principal street is Market Street, which runs nearly E. and W. a mile in length, parallel with the water. This is crossed by a number of other streets, which run from the water; a number of which, particularly Calvert and Gay streets, are well built. N. and E. of the town, the land rises, and presents a noble view of the town and bay. In 1790, this city owned 27 ships, 1 snow, 31 brigantines, 34 schooners, and 9 sloops—Total 102; tonnage 13,564. The exports in the same year amounted to 2,027,770, and the imports to 1,945,899 dollars. The exports in July, August, and Sept. in 1790, amounted only to 343,584 dollars; but in these months in 1795, they amounted to 1,675,748 dollars. The affairs of the town are managed by a board of town commissioners, a board of special commissioners, and a board of wardens; the first board fills its own vacancies, and is perpetual; the two last are appointed by electors, chosen every 5th year by the citizens. It is 53 miles S. W. from Elktown, 176 N. E. from Richmond in Virginia; 50 N. E. from the city of Washington, and 103 S. W. from Philadelphia. N. lat. 39. 21. W. long. 77. 48.—*ib.*

BANGOR, a township in Hancock co. District of Main, on the western side of Penobscot river, 25 miles from its mouth at Belfast Bay; 65 N. W. by W. from Machias; 63 N. E. from Hallowell, and 280 N. E. from Boston.—*ib.*

BANKA (see Banca, *Encycl.*) is noted throughout Asia for its tin mines. It lies opposite to the river Palambang, in the island of Sumatra, on which the sovereign of Banka, possessor also of the territory of Palambang, keeps his constant residence. This prince maintains his authority over his own subjects, and his independence of the neighbouring sovereigns, chiefly by the assistance of the Dutch, who have a settlement and troops at Palambang, and enjoy the benefit of a contract with the king of Banka for the tin which his subjects procure from that island. Such at least was the case in 1793, when Lord Macartney touched at Banka on his way to China. At that period the sovereign compelled his subjects, and probably does so at present, to deliver the tin to him at a low price, and sold it to the Dutch at a small advance, pursuant to his contract. Those miners, from long practice, have arrived at great perfection in reducing the ore into metal, employing wood as fuel in their furnaces, and not fossile coal, or *coak*, which is seldom so free from sulphur, as not to affect the malleability of the metal. It is sometimes preferred therefore to European tin at the Canton market; and the profit upon it to the Dutch company was, at the period mentioned above, supposed to have long been not less than L. 150,000 a year. Into whose hands this trade has now fallen we know not; probably it is in a great degree neglected.

BANTAM, the capital of a kingdom of the same name in the island of Java, is, in the *Encyclopædia*, said to be a large town with a good harbour and fortified castle. Sir George Staunton, however, who visited Bantam since that article was published, gives a very different account both of the town and of its harbour. Once indeed it was a place of considerable consequence, being the great mart for pepper and other spices, whence they were distributed to the rest of the world. The chief factory of the English as well as Dutch East India Company was settled there. The merchants of Arabia and Hindostan resorted to it. Its sovereigns were so desirous of encouraging trade, by giving security to foreign merchants against the violent and revengeful disposition of the natives, that the crime of murder was never pardoned when committed against a stranger, but might be committed by a foreigner for a fine to the relations of the deceased. This place flourished for a considerable time; but the Dutch having conquered the neighbouring province of Jacatra, where they since have built Batavia, and transferred their principal business to it, and the English having removed to Hindostan and China, and trade in other respects having taken a new course, Bantam was reduced to a poor remnant of its former opulence and importance. Other circumstances have accelerated its decline. The bay is so choked up with daily accessions of new earth washed down from the mountains, as well as by coral shoals extending a considerable way to the eastward, that it is inaccessible at present to vessels of burden; even the party who went there from the Lion, the ship which carried Lord Macartney to China, was obliged to remove from her pinnace into a canoe, in order to reach the town. With the trade of Bantam the power of its sovereign declined. In his wars with other princes of Java he called in the assistance of the Dutch; and from that period he became in fact their captive. He resides in a palace, built in the European style, with a fort garrisoned by a detachment from Batavia, of which the commander takes his orders not from the king of Bantam, but from a Dutch chief or governor, who lives in another fort adjoining the town, and nearer to the seaside. His Bantamese majesty is allowed, however, to maintain a body of native troops, and has several small armed vessels, by means of which he maintains authority over some parts of the south of Sumatra. His subjects are obliged to sell to him all the pepper they raise in either island, at a low price, which he is under contract with the Dutch to deliver to them at a small advance, and much under the marketable value of that commodity. The present king joins the spiritual to the temporal power, and is high priest of the religion of Mahomet; with which he mingles, indeed, some of the rites and superstitions of the aboriginal inhabitants of Java; adoring, for instance, the great banyan, or Indian fig-tree, which is likewise held sacred in Hindostan, and under which religious rites might be conveniently performed; in like manner, as all affairs of state are actually transacted by the Bantamese under some shadowing tree by moonlight. To complete the ruin of Bantam, a fire some time ago destroyed most of the houses, and few have been since rebuilt.

BANYAN TREE. See Ficus, *Encycl.*

British BARILLA, is the name given by Mr James King of Newcastle upon Tyne, to a material invented by him to supply the place of Spanish barilla in the making of crown window-glass, broad window-glass, and glass bottles, as also in the manufacturing of soap and alum. For these purposes he affirmed that it answered much better than any other material then in use; and in consequence of that affirmation he obtained a patent for his invention, dated March 4, 1780.

Though we can hardly allow to this invention all the merit claimed for it by its fond author, yet as it *may* be of use to different manufacturers, we shall lay before our readers his method of making the British barilla. It is as follows: "Take a certain quantity of ashes obtained by burning the loppings or branches of ash, oak, beech, elm, alder, or any other kind of green wood or bramble: Take an equal quantity of the ashes obtained by burning the green vegetables known by the name of fern, brecon, bean and pea-straw, whins, common field and high-way thistles, the stalks of rape or mustard-seed, or the bent or rushes that grow by the sea shore." Though we know not in what qualities the ashes obtained from the former substances differ from those obtained from the latter, the author, as if the difference was very great, directs these equal quantities to be mixed together, sifted through a fine sieve, and laid upon a boarded floor, where a quantity of soapers waste-ashes, equal to the whole compound mass, is to be added to it, and well mixed with it by means of a shovel or other instrument. To this mixture of vegetable ashes and soapers waste-ashes is to be added a quantity of fine quick-lime, in the proportion of one hundred weight to twelve hundred of the blended ashes, and the lime and ashes are to be well mixed together. After this the whole is to be put into an iron pan, into which is to be poured a quantity of sea water sufficient, says the author, to dissolve the ashes and lime; and the whole is to be stirred with an iron rake till it incorporate. This being done, a coal fire is to be lighted up under the pan, and kept burning for two days and two nights without intermission, additional quantities of sea water being constantly supplied to impregnate the materials with saline matter sufficient for calcination in a reverberating furnace or calcar. In this calcar the saline mass, which was boiled in the pan, is by intense heat to be dissolved, and kept in a state of fusion for the space of an hour; during which time the volatile part flies off, and leaves remaining a fixed alkaline salt, which, cooled in iron pans, is the British barilla, and has the appearance of Spanish barilla. See Barilla, *Encycl.*

BARNEGAT, the name of a small village of 8 or 10 houses, on the east bank of Hudson river, 5 miles S. of Poughkeepsie, and 75 N. of N. York. The sole business of the few inhabitants of this place, is burning lime, from the vast quantities of lime stone which are found here. Their lime is marketed in N. York, whither they carry it in great quantities annually.—*Morse.*

BARNET, a township in Caledonia co. Vermont, formerly in Orange co. containing 477 inhabitants, and 112 miles N. E. from Bennington. The lower bar of the 15 mile falls in Connecticut River is situated at the N. E. corner of this township. Into that river it sends Stephens River which rises in Peachum, the adjoining town on the W.—*ib.*

BARNSTABLE, the *Mattacheese*, or *Mattacheeset* of the ancient Indians, is a port of entry and post town, and is the shire town of Barnstable co. It extends across the peninsula, and is washed by the sea on the N. and S. having Sandwich, and the district called Marshpee or Mashpee on the W. is about 5 miles

miles broad, and 9 long; 67 miles S. easterly from Boston. Sandy Neck, on the N. shore, runs E. almost the length of the town, and forms the harbor, embosoming a large body of salt marsh. The harbor is about a mile wide, and 4 long; in which the tide rises from 8 to 14 feet. It has a bar running off N. E. from the Neck several miles, which prevents the entrance of large ships; but small vessels may pass any part of it at high water; and where it is commonly crossed, it seldom has less than 6 or 7 feet at low water.

There is another harbor on the S. called *Lewis's Bay*. Its entrance is within Barnstable, and it extends almost 2 miles into Yarmouth. It is commodious and safe, and is completely land locked; and has 5 feet water at a middling tide.

A mile or two to the westward, and near the entrance of Lewis's Bay, lies *Hyanis Road*. It is formed principally by an island, joined by a beach to Yarmouth, which together, make the outside of the bay before mentioned. The S. head of this island is called Point Gammon. Oyster Bay, near the S. W. limit of the town, admits small vessels; and which, with Lewis's Bay, has in years past produced excellent oysters, in great quantities; though they are now much reduced.

There are about 20 or 30 ponds in Barnstable. The land here produces about 25 bushels of Indian corn to an acre, and rye and other grain in proportion. Wheat and flax are cultivated; the latter with success. From 12 to 18,000 bushels of onions are raised for the supply of the neighboring towns. Upwards of 100 men are employed in the fishery, which is yearly increasing. Whales seldom come into Massachusetts Bay now, and that fishery is discontinued. No quarrels with the ancient natives of the country are recorded in the accounts of this town, where the English settlers of New-England first landed, Nov. 11, 1620. The people, 2610 in number, are generally healthy; and many instances of longevity are to be met with. Numbers of the farmers are occasionally seamen; and this town has afforded, and continues to furnish many masters of vessels and mariners who sail from other ports. N. lat. 41. 43.—*Morse.*

BARNSTEAD, a township in Stafford co. New-Hampshire, containing 807 inhabitants; 22 miles N. W. of Portsmouth, and 16 E. by S. from Canterbury, on Connecticut river.—*ib.*

BARRE', a township in Worcester co. Massachusetts, containing 1613 inhabitants, 24 miles N. W. of Worcester, and 66 W. of Boston, deriving its name from Col. Barré, a British senator, who on the eve of the late war, plead the cause of America, in the British house of commons, with great, but unsuccessful energy. This town has good pastures, and here are fatted multitudes of cattle; and it is supposed, more butter and cheese is carried from hence to the market, annually, than any other town of the same size in the State. —*ib.*

Barre', a township in Huntingdon co. Pennsylvania.—*ib.*

BARRELL's *Sound*, on the N. W. Coast of America, called by the natives *Conget-hoi-toi*, is situated about 6 leagues from the southern extremity of Washington, or Charlotte islands, in a N. W. direction, about N. lat. 52. W. long. 131. from Greenwich. It has two inlets; one on the E. the other W. side of the island; the latter is the best, the other is dangerous. The shores are of a craggy black rock; the banks lined with trees of various kinds, as pines, spruce, hemlock, alder, &c. Mr Hoskins, in the summer of 1791, measured one of these trees, which was *ten fathoms* in circumference. On one side of it a hole had been cut, large enough to admit a man; within was a spacious and convenient room, which had apparently been dug and burnt out with much labor. Mr Hoskins concluded that it must have been occasionally inhabited by the natives; as he found in it a box, fireworks, dried wood, and several domestic utensils. This sound was named after Joseph Barrell, Esq. of Charlestown, *(Mass.)* and was first visited by Capt. Gray, in the Washington, in 1789.—*Morse.*

BARREN *Creek*, rises in the N. W. corner of Delaware state, runs about 9 miles S. westerly, and empties into Nanticoke river. A triangular tract of land in the N. part of Somerset co. Maryland, is enclosed between this creek on the S. Delaware state E. and Nanticoke river on the W. and N. W.—*ib.*

BARRINGTON, a township in Queen's co. Nova-Scotia, on the S. side of the bay of Fundy; settled by Quakers from Nantucket Island.—*ib.*

Barrington, a township in Stafford co. N. Hampshire, about 30 miles N. W. from Portsmouth, incorporated in 1722, containing 2470 inhabitants. Allum is found here; and the first ridge of the *Frost Hills*, one of the three inferior summits of Agamenticus, is continued through this town. Its situation is very healthy; *e. g.* 14 of the first settlers in 1732, were alive in 1785, who were between 80 and 90 years old. —*ib.*

Barrington, a township in Bristol co. Rhode-Island, on the S. western side of the N. W. branch of Warren river, little more than 2½ miles N. W. of Warren, and about 7 S. E. from Fox Point, in the town of Providence. It contains 683 inhabitants, including, 12 slaves.—*ib.*

Barrington, Great, is the second township in rank in Berkshire co. Massachusetts. It contains 1373 inhabitants, and lies 140 miles W. from Boston, and south of Stockbridge, adjoining.—*ib.*

BARTHELEMI (Jean Jacques), the Nestor of French literature, was a man so eminent for his knowledge of antiquities, that every classical reader must be interested in his fate. He was born, we believe, at Paris about the latter end of the year 1715; and being educated for the service of the church, he became prior of Courcay, keeper of the medals and antiques in the French king's cabinet, and in 1747 was elected a member of the Academy of Inscriptions. From that period his life was wholly devoted to letters; and in recording the principal events of it, we can only enumerate, in their order, his various publications.

A dissertation of his on the river Pactolus was read 1748 *(Hist. de l'Acad.* X. 29.); Reflections on a Medal of Xerxes, King of Arsamata *(Mem. de l'Acad.* XXXVII. 171.), found, or said to be found, by Fourmont in the temple of Apollo Anycleus (XXXIX. 129.); Essay on Numismatic Palæography, *ib.* 223; Dissertation on two Samaritan Medals of Antigonus King of Judea, *ib.* 257; Remarks on some Inscriptions published

Barthelemi

published by different authors, XLV. 99; Dissertation on Arabic Coins, *ib.* 143; by which it appears that the Mohammedan princes copied the heads of Greek and Roman ones on their coins, and gave Arabic inscriptions of their own names on the reverse. On the Ancient Alphabet and Language of Palmyra, *ib.* 179; on the Ancient Monuments of Rome, the result of a tour in Italy to collect medals for the royal cabinet, to which he added 300, XLIX. 151; on some Phœnician Monuments, and the Alphabets formed from them, LIII. 23. The characters on the written mountains, which he here cites, have been proved of no value; and he illustrates the conformity between the Phœnician and the Egyptian characters from the latter on the bandages of the mummies. Explanation of the Mosaic Pavement of the Temple of Præneste, *ib.* 149; of which there have been four engravings since its first discovery in 1650, and which Barthelemi refers to the voyage of Adrian into Egypt. It may be of that date, but there is no reason to suppose that it represents any thing more than an Egyptian landscape. The form of letters determines the date in the judgment of the learned Abbé. On the Relations of the Egyptian, Phœnician, and Greek Languages, LVII. 383; on some Medals published by different authors, LIX. 270; Explanation of an Inscription under a Bas-relief in the Bishop of Carpentras's Library, 1767, *ib.* 365; on the Number of Pieces represented in one Day on the Theatre at Athens, LXXII. 286; three Comedies, as many Tragedies, a Satire, and a Petite Piece; Remarks on some Medals of the Emperor Antoninus struck in Egypt, LXXX. 484. 1775 (A).

His interpretation of the Phœnician inscription at Malta, LIII. 23, was controverted by our learned linguist, Mr Swinton, in Philos. Transact. LIV. art. xxii. p. 119; in farther remarks, *ib.* art. lxx. p. 393.

In 1792 he published a dissertation on an ancient Greek inscription, containing an account of expences of the public feasts under the archontate of Glaucippus, 410 years before Christ.

The intimate acquaintance which he had cultivated with classical antiquity, enabled him, in the close of a long life, to compose that *chef-d'œuvre*, the "Travels of the Younger Anacharsis into Greece" in the middle of the fourth century before the vulgar era. In representing the curiosity of a Scythian savage (for we cannot consider in any other light the man who put music and the excesses of the table on the same level), he takes occasion to interweave very curious and instructive details on the laws, religion, manners, customs, and general spirit, of a great nation, as well as its progress in arts and sciences. The epoch which he has chosen is that of letters and arts, combining the age of Pericles with that of Alexander, the revolution which changed the appearance of Greece, and soon after overturned the empire of Persia. The introduction comprehends the 1250 years elapsed from the age of Cecrops to the supposed era of Anacharsis, in two intervals; the first reaching to the commencement of the Olympiads, the second to the capture of Athens by the Lacedemonians. The history of the Athenians commences about 150 years after the first Olympiad, including the age of Solon, or that of legislation; that of Themistocles and Aristides, or that of glory, of luxury, and arts. In the second, speaking of war, his observation, that "the example of one nation, that prefers death to slavery, is too important and too instructive to be passed in silence," should have preserved him from the horrors of a long confinement in an advanced age, from which he was delivered only to die. But arts, sciences, and literature, are alike forgotten and overwhelmed in France. In the third interval, speaking of the corruption of manners introduced by Pericles to support his power, he has this observation, applicable to every state: "Corrupted morals are not restored but by the loss of liberty, which brings that poverty inconsistent with softness, and inseparable from abstemiousness, if not that rigid principle of a healthy mind, which is properly called *virtue*." In this period, though the arts were encouraged, philosophy was neglected.

In this diversified undertaking, where the picture of ancient Greece in its minutest parts, both of public and private use, is brought before our eyes, the Abbé is frequently more brilliant than solid, and occasionally loses the substance of a reflection in pursuit of something ingenious to add to it. The plans, views, and maps, are executed with great spirit and accuracy by Mr Barber, a young man of very promising talents; and to the charts many useful tables are added. The beauties of the classics are diffused in a very pleasing manner, and interspersed with anecdotes little known.

Such was the man whom the French government detained in prison for months, and released on the fall of Robespierre. As he concurred in the revolution, we know of no cause for his imprisonment but the mildness of his disposition, and the jealousy of that tyrant, which pursued, with relentless cruelty, every man suspected of being a friend to peace. Of the persecution of Barthelemi, in the extremity of old age, the convention itself seemed to be ashamed; for it unanimously voted him a pension as some recompence for his sufferings. But, alas! the recompence came too late: the old man lived but a few months after his liberation, having died at Paris on the 4th of May 1795; and the day after the following tribute was paid to his memory by Dussaulx, in the national convention:

"Legislators, your liberality conferred honour on the latter days of the life of our respectable fellow citizen, Barthelemi. Our successors, I have no doubt, will consecrate his memory so soon as the period fixed by the law shall permit them. May his old friend, however, be permitted, in a few words, to point out the rare qualities of that Nestor of French literature? It might, perhaps, be sufficient to tell you, as Xenophon said with so much simplicity of one of his most illustrious contemporaries, that Barthelemi was an excellent man in all respects. In fact, those who knew him were at a loss which to admire most—his immortal Anacharsis, or his own life. His policy consisted in goodness; his science was an immense treasure of every thing that could purify the morals, perfect the taste, render man more dear to man, and contribute to the splendour of his

(A) The references here are to the duodecimo edition of the Memoirs of the Academy of Inscriptions.

his country. A ſingle trait will convince you of the mildneſs of his philanthropic mind: 'Why is it not permitted (he often ſaid) to a mortal to bequeath proſperity to his fellow-creatures?' After having been overwhelmed with the favours of fortune, which came unexpectedly and unſought, he became poor; yet his character, far from ſinking under the preſſure, acquired new reſpect; and he proved that poverty, ſupported with dignity, is not leſs honourable than wealth accompanied with benevolence. Perſecuted, as all virtuous and enlightened citizens were, he carried with him to the dungeon of that tyranny which you have ſo gloriouſly deſtroyed, the conſtancy and ſerenity of Socrates. It was there that the venerable old man offered to his companions in misfortune the magnificent ſpectacle of a good man ſtruggling with adverſity. I have ſaid that he was rich; but let us not forget that he was not rich at the expence of the unfortunate, and that he adopted all the branches of his numerous family. The republic has gained by that family good citizens, who ſerve her in the moſt uſeful and brilliant manner. Barthelemi felt that the period of his diſſolution was approaching; yet though exhauſted by long fatigue, and bending beneath the weight of 80 years, his ſenſibility was ſtill vigorous, and your juſt decrees made the cloſing ſcene of his life happy. When he heard that you were endeavouring to repair the ills under which ſo many thouſand innocent men laboured, he lifted up his hands to heaven, and exclaimed, 'Glory to God—honour to the national convention—I have lived long enough!' In the preſent poſture of affairs, the country demands all your attention. I ſhall therefore confine myſelf to requeſt the favour due to the manes of the illuſtrious Barthelemi. One of his nephews, I do not mean your reſpectable ambaſſador at Baſle, but the citizen Courcey, has, for 25 years, diſcharged all the duties of a ſon to his uncle, and for a long time has performed the functions of keeper of the medals and antiquities of the national cabinet. I move, that the citizen Courcey be appointed to that office, which he has already proved himſelf ſo worthy to fill."

Whatever became of this motion, which was referred to the committee of public inſtruction, the cruelty of the government purſued the family; and the late baniſhment of his other nephew by the directory, of which he was a member, ſurpaſſes, if poſſible, the injuſtice of Robeſpierre to the uncle. But their crimes were the ſame: both Barthelemis were men of mild diſpoſitions and friends to peace.

BARTHOLOMEW, St. a pariſh in Charleſton diſtrict, S. Carolina, containing 2.138 white perſons. By the cenſus of 1790, it contained 12,606 inhabitants, of whom 10.338 were ſlaves. It ſends 3 repreſentatives and 1 ſenator to the ſtate legiſlature. Amount of taxes £1,566-10 4 ſterling.—*Morse.*

Bartholomew St. one of the Caribbee iſlands, in the W. Indies, 25 miles N. of St. Chriſtopher's, and 30 N. E. of Saba. It is reckoned 5 leagues in circumference, but has little ground fit for manuring. It produces tobacco, caſſava, and abounds with woods. The trees moſt in eſteem are, 1. The ſoap tree, or aloes tree. 2. The calaback. 3. The canapia, whoſe gum is an excellent catharic. 4. The parotane, whoſe boughs grow downward, take root again, and form a kind of bulwark and ſtrong defence in time of attack. All along the ſhore are thoſe trees called Sea Trees, whoſe boughs are curiouſly plaited together, and look as if they were glazed. Here is an infinite variety of birds, and a peculiar kind of lime ſtone, which the inhabitants export to the adjacent iſlands. They have likewiſe plenty of lignumvitæ and iron wood. Its ſhores are dangerous, and the approaching them requires a good pilot; but it has an excellent harbour, in which ſhips of any ſize are ſheltered from all winds. Half its inhabitants are Iriſh Roman Catholics, whoſe predeceſſors ſettled here in 1666; the others are French, to whom the iſland lately belonged. It was ceded by France to the crown of Sweden in 1785. They depend on the ſkies for water, which they keep in ciſterns. It was a neſt for privateers when in the hands of the French; and at one time had 50 Britiſh prizes in its harbor. N. lat. 17, 56. W. long. 63. 10.—*ib.*

BARTRAM (John) a celebrated ſelf-taught philoſopher and botaniſt, was born near the village of Darby in Cheſter county, Pennſylvania, in the year 1701. His grandfather John Bartram with his family from Derbyſhire in England, came over with the adherents of the famous William Penn, when he eſtabliſhed the colony of Pennſylvania in 1682.

He very early in life manifeſted an ardent thirſt for knowledge; but the great diſtance from Europe, then the ſeat of arts and ſciences, and the infant ſtate of the colony, rendered it difficult to obtain even a moderate education: however the reſources of his own mind, and the moſt intenſe application ſurmounted the difficulties of his ſituation. Aſſociating with the moſt reſpectable characters, he obtained the rudiments of the learned languages, which he ſtudied with extraordinary application and ſucceſs. So earneſt was he in the purſuit of learning that he ſeldom ſat at his meals without his book, often his victuals in one hand and his book in the other. He had an early inclination for the ſtudy of medicine and ſurgery, and acquired ſo much knowledge as to adminiſter great relief to the indigent and diſtreſſed in his neighbourhood; and as moſt of his medicines were drawn from the vegetable kingdom, this furniſhed him with opportunity for proſecuting the ſtudy of botany which was his favourite object, together with natural hiſtory. Bred a huſbandman, he cultivated the ground as the principal means of ſupporting a large family, he proſecuted his avocations as a philoſopher, being attentive to the œconomy of nature, and obſerving her moſt minute operations. When ploughing or ſowing his fields or mowing his meadows, his inquiſitive mind was exerciſed in the contemplation of the vegetable ſyſtem and of animated nature.

He was the firſt American who conceived and carried into effect the deſign of a botanic garden for the reception and cultivation of American vegetables as well as exotics, and of travelling for the acquiſition of them: and for the purpoſe of accompliſhing this ſcheme he purchaſed a plantation in a delightful ſituation on the banks of the Schuylkill, about five miles from Philadelphia, where he laid out with his own hands, a large garden, containing ſix or ſeven acres comprehending a variety of ſoils and ſituations, which he ſoon furniſhed with a great variety of the moſt curious and beautiful vegetables, collected in his various

excurſions

Bartram. excursions in different parts from Canada to Florida. Botany being his favourite pursuit he soon made such proficiency therein that the great Linnæus said in one of his letters, that he was the greatest natural botanist in the world. His progress in botany, natural history and philosophy, attracted the notice and esteem of the principal literary and eminent characters in America, among whom were James Logan, Esq. Dr Franklin and Dr Kennersley of Philadelphia, Dr Colden of New York and Dr Clayton of Virginia, and introduced him to the correspondence and friendship of Peter Collinson, Esq. which continued for nearly fifty years and terminated only with life; Lord Petre, Dr Dillenius, Sir Hans Sloane, Mr Catesby, Dr Fothergill, Dr Hill, Gronovius, Linnæus, Professor Kalm, M. Wrangle, &c. who furnished him with such books, philosophical apparatus, &c. as his genius and situation required, thereby lessening the difficulties with which he had to struggle in a newly settled country, and promoting the object which his benevolent mind had contemplated in communicating his discoveries and collections to Europe. These communications occasioned him to be employed in collecting whatever was new and curious to furnish and ornament the European gardens and plantations with the productions of the New World. His industry and success in the pursuit of science procured him fellowship in many literary and scientific societies in Europe, as those of London, Edinburgh, Stockholm, &c. and at last he was appointed American Botanist to his Britannic Majesty George the Third, in which appointment he continued till his death in September 1777, in the Seventy-sixth year of his age.

He employed much of his time in excursions through the provinces then subject to England; chiefly in autumn, when his agricultural avocations least required his presence at home. The object of these journeys was to collect curious and non-descript vegetables, fossils, &c. His ardour in these pursuits was such that at the age of 70 he made a journey into East Florida to explore the natural productions of that country. His travels among the Native Indians were attended with much danger and difficulty, and the different parts of the country, from the shores of Lakes Ontario and Caiuga to the source of the river St Juan in E. Florida, contributed through his hands to enrich and embellish the gardens and forests of Europe with elegant flowering shrubs, plants, and useful and ornamental trees.

He was an ingenious mechanic, several monuments of which still remain at the house in which he lived which he built himself, after quarrying the stone: and he was often his own mason, carpenter, black-smith, &c. and generally made his own farming utensils.

His stature was rather above the middle size, erect and slender, a sandy complection, cheerful countenance, with an air of solemnity, his manners modest and gentle, an amiable disposition and liberal mind, a lover of charity and social order, he was never known to enter into a litigious contest with any one, active and temperate, but always maintained a plentiful table, and annually on new year's day he made an entertainment at his own house, consecrated to friendship and philosophy. He was an advocate for liberty, and for the abolition of Negro slavery, and gave freedom to an excellent young African whom he had brought up, and who continued gratefully in his service while he lived. Born and educated in the Society of Friends (called Quakers) he was a pious man. The following distich was engraved by himself on a stone in the wall over the front window of his own apartment.

> " 'Tis God alone, the Almighty Lord,
> " The Holy One by me ador'd."

JOHN BARTRAM, 1770.

Barytes || Batavia.

BARYTES, one of the earths. See Chemistry in this Supplement, Part I. Chap. iv.

BASTER, the name given by the Dutch at the Cape of Good Hope to the offspring of a white man and Hottentot woman.

BAT, an animal which has been described under its generic name Vespertillio in the *Encycl.* but since that article was written, we have met with an account of a new species, so very singular, that, if the veracity of our author can be depended on, it is well intitled to a place here. This species was discovered in the country of the Nimiquas, in the interior of Africa, by *M. Vaillant*, during the course of his second travels, and is by him called the *oreillar* bat. To this title it has indeed a very good claim; for it has, he says, four ears, or at least the external part of four ears, each ear being double; the outer fold, which serves as a covering to the inner, is very ample, being two inches eight lines high, and nearly as broad when stretched out. On the nose also a membrane stands erect, one inch four lines in height, which might be taken for another ear, as it has exactly the shape of one. This membrane, as well as the ears and wings of the animal, are of a rusty red, paler below than above. The body is only three inches long, and is covered with very fine greyish hair. Its width, from the tip of one wing to that of the other, is eight inches. The reader will pardon me, says our author, for inserting these trifling details of measurement, of which I am not more fond than himself; but they appeared to me necessary here, to convey an accurate idea of the extraordinary length of the ears of this animal, which are certainly larger in proportion than those of any other we are acquainted with, since they are only four lines, or the third part of an inch, shorter than the body itself.

BATAVIA, the capital of the Dutch settlements in the East Indies, has been already described under the article Java in the Encyclopædia. The following account of it, however, as well as of the country around it, and the manners and customs of its various inhabitants, as they presented themselves to Sir George Staunton in March 1793, will probably prove acceptable to many of our readers.

The city of Batavia, including the suburbs, consists of near eight thousand houses, inhabited by Dutch, Chinese, and natives of Java. The houses of the Chinese are low, and crammed with people. The Dutch houses are well built, clean, and spacious, and their construction for the most part well suited to the climate. The doors and windows are wide and lofty. The ground floors are covered with flags of marble, which being sprinkled frequently with water, give a pleasant coolness to the apartment; but a considerable proportion of those was untenanted, which denoted a declining settlement. Among other circumstances which announced the same, were those of the Company's vessels lying useless ufelefs in the road, for want of cargoes to fill, or men to navigate them ; no fhips of war to protect their commerce, even againft pirates, who attacked their veffels fometimes in the fight of Batavia road ; an invafion threatened from the Ifle of France ; the place in no condition of defence, particularly againft an enemy lefs affected by the climate than Europeans ; fometimes as many of the troops in hofpitals as fit for duty ; commiffioners expected from Holland to reform abufes. Such a commiffion, implying a general fufpicion, could not be welcome ; nor was it quite certain whether, in fome minds, its arrival or that of the enemy was deprecated the moft cordially.

The fortifications of Batavia, though a place of fo much importance, were not, when Sir George faw them, fuch as would be deemed formidable in Europe ; but when the difficulties were confidered of forcing the paffage of the river, or of landing troops on other parts of the ifland, it might perhaps be thought of greater ftrength than it would at the firft view have credit for. The defences of the river were the water fort, fituated at its entrance, having mounted or difmounted fourteen guns and two howitzers. It confifted of a parapet, originally well conftructed, retained by a wall ; but the parapet was much neglected, and the wall nearly deftroyed by the conftant working of the fea. This fort was protected on the land fide by a noxious fwamp, and towards the fea, on the northweft, by extenfive flats, over which even boats could not pafs. The only good approach was that by the channel, which it fees and defends. The next work upon the river was on the weft fhore, about a quarter of a mile from the water fort. It is a battery mounting feven guns, bearing down the river. Oppofite to this was a battery of fix guns, facing the river, and two to the eaftward. This formed one flank of a line that occupied the low land to the north-eaft of the town. The line was a low breaft-work of earth, that was fcarcely difcoverable. The canals which interfect the town joined the great canal or river, at the diftance of half a mile from the entrance. Below the junction a boom was laid of wood, armed with iron fpikes. A little above was the caftle, a regular fquare fort, but without ravelins or other outworks. It had two guns mounted on each flank, and two, or fometimes three, on each face : they were not *en barbette*, nor properly *en embrafure*, but in a fituation between both, having both their difadvantages without the advantage of either. The wall was of mafonry, about 24 feet high. It had no ditch, but a canal furrounded it at fome diftance. It had no cordon. The length of the exterior fide of the work was about 700 feet. The town is rectangular, three quarters of a mile long, and half a mile broad, inclofed by a wall of about 20 feet in height. Small projections were conftructed, of various forms, at intervals of about 350 feet. Thefe generally mounted three guns each. It was alfo furrounded by a canal, having feveral fluices. At fhort diftances from the town, three or four fmall ftar forts of earth were erected in particular paffes, perhaps for defence againft the inhabitants of the ifland.

The eftablifhment of regular troops was 1200 Europeans, of whom 300 were to be artillery, the reft infantry. But as it was found impoffible, on account of the climate, to keep the number complete, recourfe was had to the natives, of whom 500 were employed ; fo that the eftablifhment of European regulars was reduced to 700. There were alfo 300 volunteers of the town, who were formed into two companies, but they were not difciplined. Their regulars were very numerous, confifting of enrolled natives of Java, who were never embodied, and of Chinefe, of whom the Dutch were fo jealous as to arm them with lances only. Much dependence was not to be placed on the exertions of either of thefe bodies in favour of the Dutch ; and as they lofe many of their European troops every year, their eftablifhment appeared too fmall for any effectual refiftance. The chief protection of their ill-manned veffels lying here, muft be from the fortified ifland of Onruft, well fituated to command the channel that affords the principal paffage into the road. The work upon that ifland was of a pentagonal form ; its baftions were fmall and low, not more than 12 feet the higheft, and not always connected by curtains. A few batteries were lately conftructed on the outfide of this work, that bore towards the fea. On thefe and on the baftions about 40 guns were mounted in different directions. South of thefe was another ifland, at the diftance of a few hundred yards, on which two batteries, mounting together 12 guns, had been lately erected.

The caftle is built of coral rock, brought from fome of the adjoining iflands, compofed of that material ; and has the advantage of a fortification of brick, in which cannon ball is apt to bury itfelf without fpreading fplinters or fhattering the wall. A part of the town wall is built of lava, which is of a dark blue colour, of a very hard denfe texture, emits a metallic found, and refembles very much fome of the lava of Vefuvius. It is brought from the mountains in the centre of Java, where a crater is ftill fmoking. No ftone of any kind is to be found for many miles behind the city of Batavia. Marble and granite are brought thither from China, in veffels belonging to that country, commonly called *junks*, which generally fail for Batavia from the ports of the provinces of Canton and Fokien, on the fouthern and fouth-eaft coafts of that empire, laden chiefly with tea, porcelain, and filks.

The chief protection of Batavia againft the attacks of a foreign enemy, arifes from the havoc which it is well known the climate would make amongft European troops. This was acknowledged to Lord Macartney by fome of the Dutch officers themfelves, and even by one of the counfellors of the Indies. Such indeed is the climate, that there have been very few examples of ftrangers remaining long in Batavia without being attacked by fever, which is the general denomination in that place for illnefs of every kind. Europeans foon after their arrival firft become languid and feeble, and in a few weeks, or even in a few days, are taken ferioufly ill. The diforder at firft is commonly a tertian ague, which after two or three paroxyfms becomes a double tertian, and then a continued remittent, that frequently carries off the patient in a fhort time. Many fall victims to the fecond or third fit ; but in thefe cafes a conftant delirium, and a great determination of the blood to the brain, accompany the other fymptoms. In fome it begins in a quotidian form, with regular intermiffions for a day or two ; and then becomes a continued remittent, attended with the fame fatal confequences as the former. Of the Europeans of all claffes who come to to ſettle at Batavia, it is ſuppoſed that not half the number always ſurvives the year. The place reſembles in that reſpect a field of battle or a town beſieged. The frequency of deaths renders familiar the mention of them, and little ſigns are ſhewn of emotion or ſurpriſe on hearing that the companion of yeſterday is to-day no more. It is probable, female Europeans ſuffer leſs at Batavia than the men. The former ſeldom expoſe themſelves to the heat of the ſun, make frequent uſe of the cold bath, and live more temperately than the other ſex.

But it is not to thoſe who have lately arrived from Europe that this havoc is wholly confined. The greateſt number of the Dutch ſettlers, even thoſe who had reſided long in the country, appeared wan, weak, and languid, as if labouring with the "diſeaſe of death." Their place of reſidence, indeed, is ſituated in the midſt of ſwamps and ſtagnated pools, from whence they are every morning ſaluted with "a congregation of foul and peſtilential vapours," whenever the ſea breeze ſets in, and blows over this moraſs. The meridian ſun raiſes from the ſhallow and muddy canals, with which the town is interſected, deleterious miaſmata into the air; and the trees, with which the quays and ſtreets are crowded, emit noxious exhalations in the night.

The general reputation of the unhealthineſs of Batavia is indeed ſuch as to deter even Dutchmen, who can reſide at home with any comfort, from coming to it, notwithſtanding the temptations of fortunes to be quickly amaſſed in it. From this circumſtance it happens, that offices and profeſſions are often neceſſarily entruſted to perſons little qualified to fill them. One of the clergymen, and the principal phyſician of the place, were both ſaid to have originally been barbers. The United Provinces furniſh even few military recruits. The reſt are chiefly Germans, many of whom are ſaid to have been kidnapped into the ſervice. Though nominally permitted, after a certain length of time, to return home, they are in fact compelled to enliſt for a longer time, the pay being too ſcanty to allow them to ſave enough to defray the expence of their paſſage to Europe. The government is accuſed of the barbarous policy of intercepting all correſpondence between theſe people and their mother country; by which means they are deprived of the conſolation of hearing from their friends, as well as of the chance of receiving ſuch aſſiſtance as might enable them to get home.

Difficult, however, as it is, on account of the climate, to recruit the army, ſuch is the deſire of accumulating wealth in a foreign land, that it draws annually great numbers of Chineſe as well as of Dutch to Batavia. Both indeed belong generally to the humbler claſſes of life, and are bred in ſimilar habits of induſtry in their own country; but the different circumſtances that attend them after their arrival in Batavia put an end to any further reſemblance between them. The Chineſe have there no way of getting forward but by the continuance of their former exertions in a place where they are more liberally rewarded, and by a ſtrict economy in the preſervation of their gains. They have no chance of advancing by favour, nor are public offices open to their ambition; but they apply to every induſtrious occupation, and obtain whatever either care or labour can accompliſh. They become in town retailers, clerks, and agents; in the country they are farmers, and are the principal cultivators of the ſugar-cane. They do at length acquire fortunes, which they value by the time and labour required to earn them. So gradual an acquiſition makes no change in their diſpoſition or mode of life. Their induſtry is not diminiſhed, nor their health impaired. The Dutch, on the contrary, who are ſent out by the Company to adminiſter their affairs in Aſia, become ſoon ſenſible that they have the power, wealth, and poſſeſſions of the country at their diſpoſal. They who ſurvive mount quickly into offices that are lucrative, and not to them laborious. They riſe to the dignity of governor-general and counſellors of the Indies, as the members of the Batavian government are called. Their influence likewiſe enables them to ſpeculate in trade with vaſt advantage. The drudgery and detail of buſineſs are readily undertaken by the Chineſe; while their principals find it difficult, under ſuch new circumſtances, to retain their former habits, or to reſiſt a propenſity to indolence and voluptuouſneſs, though often attended with the ſacrifice of health, if not of life. Convivial pleaſures, among others, are frequently carried to exceſs.

In ſeveral houſes of note throughout the ſettlement, the table is ſpread in the morning at an early hour: beſide tea, coffee, and chocolate, fiſh and fleſh are ſerved for breakfaſt; which is no ſooner over than Madeira, claret, gin, Dutch ſmall beer, and Engliſh porter, are laid out in the portico before the door of the great hall, and pipes and tobacco preſented to every gueſt, and a bright braſs jar placed before him to receive the phlegm which the tobacco frequently draws forth. This occupation continues ſometimes with little interruption till near dinner time, which is about one o'clock in the afternoon. It is not very uncommon for one man to drink a bottle of wine in this manner before dinner; and thoſe who have a predilection for the liquor of their own country ſwallow ſeveral bottles of Dutch ſmall beer, which they are told dilutes their blood, and affords plenty of fluids for a free perſpiration. Immediately before dinner, two men ſlaves go round with Madeira wine, of which each of the company takes a bumper as a tonic or whetter of the appetite. Then follow three females, one with a ſilver jar containing water, ſometimes roſe-water, to waſh; a ſecond with a ſilver baſon and low cover of the ſame metal, pierced with holes, to receive the water after being uſed; and the third with towels for wiping the hands. During dinner a band of muſic plays at a little diſtance: the muſicians are all ſlaves, and pains are taken to inſtruct them. A conſiderable number of female ſlaves attend at table, which is covered with a great variety of diſhes; but little is received, except liquors, into ſtomachs already cloyed. Coffee immediately follows dinner. The 24 hours are here divided, as to the manner of living, into two days and two nights; for each perſon retires, ſoon after drinking coffee, to a bed, which conſiſts of a mattraſs, bolſter, pillow, and chintz counterpane, but no ſheets; and puts on his night dreſs, or muſlin cap and looſe long cotton gown. If a bachelor, which is the caſe of much the greateſt number, a female ſlave attends to fan him while he ſleeps. About ſix they riſe, dreſs, drink tea, take an airing in their carriages, and form parties to ſpend the evening together to a late hour. The morning meetings conſiſt generally of men, the ladies ſeldom chooſing to appear till evening.

Few of theſe are natives of Europe, but many are deſcended

Batavia. descended from Dutch settlers here, and are educated with some care. The features and outlines of their faces are European; but the complexion, character, and mode of life, approach more to those of the native inhabitants of Java. A pale languor overspreads the countenance, and not the least tint of rose is seen in any cheek. While in their own houses they dress like their slaves, with a long red checkered cotton gown descending to the ankles, with large wide sleeves. They wear no head dress, but plait their hair, and fasten it with a silver bodkin on the top of the head, like the country girls in several cantons of Switzerland. The colour of their hair is almost universally black; they anoint it with the oil of the cocoa nut, and adorn it with chaplets of flowers. When they go abroad to pay visits, or to take an airing in their carriages, and particularly when they go to their evening parties, they dress magnificently, in gold and silver spangled muslin robes, with a profusion of jewels in their hair, which however, is worn without powder. They never attempt to mould or regulate the shape by any fancied idea of elegance, or any standard of fashion; and consequently formed a striking contrast with such few ladies as were lately arrived from Holland, who had powdered hair and fair complexions, had contracted their waists with stays, wore large head dresses and hoops, and persevered in the early care of forcing back the elbows, chin, and shoulders. Every native lady is constantly attended by a female slave handsomely habited, who, as soon as her mistress is seated, sits at her feet before her, on the floor, holding in her hands her mistress's gold or silver box, divided into compartments, to contain areca nut, cardamom seeds, pepper, tobacco, and slacked lime; all which, mixed together in due proportions, and rolled within a leaf of betel, constitute a masticatory of a very pungent taste, and in general use. When in the public assemblies the ladies find the heat disagreeable, they retire to free themselves from their costly but inconvenient habits, and return without ceremony in a more light and loose attire, when they are scarcely recognizable by strangers. The gentlemen follow the example; and throwing off their heavy and formal dresses, appear in white jackets, sometimes indeed adorned with diamond buttons. The elderly gentlemen quit their periwigs for nightcaps. Except in these moments the members of this government have always combined their personal gratification with the Eastern policy of striking awe into vulgar minds, by the assumption of exterior and exclusive distinctions. They alone, for instance, appear abroad in crimson velvet. Their carriages are distinguished by peculiar ornaments. When met by others, the latter must stop and pay homage to the former. One of the gates of the city is opened only to let them pass. They certainly succeed in supporting absolute sway over a vast superiority in number of the descendents of the original inhabitants of the country, as well as of the slaves imported into it, and of the Chinese attracted to it by the hope of gain; those classes, though healthy, active, and as if quite at home, readily obeying a few emaciated Europeans. Such is the consequence of dominion once acquired; the prevalence of the mind over mere bodily exertions, and the effect of the combination of power against divided strength.

The native Javanese are in general too remote from civilization to have any wants that are not easily satisfied in a warm and fertile climate. No attempt is made to enslave their persons; and they find the government of the Dutch less vexatious than that of others, who divide some share of the sovereignty of the island with them. The sultan of Mataran rules to the east, the emperor of Java in the centre, and the king of Bantam to the west; while the coast and effective power almost entirely belong to Holland. Those other sovereigns are descended from foreigners also; being Arabians, who imported the Mahometan religion into Java, and acquired the dominion of the country; a few inhabitants in the mountains excepted, who have preserved their independence and their faith, and among other articles that of the transmigration of souls. According to the Dutch accounts, nothing can be more tyrannic than those Mahometan rulers. The emperor is said to maintain his authority by an army of many thousand men dispersed throughout his territories, beside a numerous female guard about his person. These military ladies are trained, it seems, to arms, without neglecting those accomplishments which may occasion a change in the occupation of some among them, rendering them the companions, instead of being the attendants, of his Imperial majesty. This singular institution may owe its origin to the facility of obtaining recruits, if it be true, as the same accounts pretend, that the number of female births exceeds very considerably that of males in Java.

Most of the slaves are imported into it from Celebes and other eastern islands. They do not form a corps, or have any bond of union: nor is the general conduct of their owners towards them calculated to aggravate the misfortune of being the property of others. They are not forced to excessive labour. They have sufficient sustenance; but many of the males among them, who had formerly perhaps led an independent life till made captives in their wars, have been found to take offence against their masters upon very slight occasions, and to wreak their vengeance by assassination. The apprehension of such an event is among the motives for preferring at Batavia female slaves for every use to which they can be applied; so that the number purchased of them much exceeds that of the other sex. The slaves when determined on revenge often swallow, for the purpose of acquiring artificial courage, an extraordinary dose of opium, and soon becoming frantic as well as desperate, not only stab the objects of their hate, but sally forth to attack in like manner every person they meet, till self-preservation renders it necessary to destroy them. They are said in that state to be *running a muck*; and instances of it are not more common among slaves than among free natives of the country, who in the anguish for losing their money, effects, and sometimes their families, at gaming, to which they are violently addicted, or under the pressure of some other passion or misfortune, have recourse to the same remedy, with the same fatal effects.

In the country round Batavia the eye looks in vain for the common animals and vegetables which it had been daily accustomed to meet in Europe. The most familiar bird about the house of the embassador's host was the crown bird, as it was called at Batavia, which was not, however, the *ardea pavonina* of Linnæus, but the *columba cristata*, having nothing except its crest in common with the former. The same gentleman had also at his country house some large cassowary birds, which, though long in his possession, and having the appearance of tameness, sometimes betrayed the fierceness of their nature, attacking with their strong bill those who approached too near them. The vegetation of the country is likewise new. Even the parterres in the gardens are bordered, instead of boxwood, by the Arabian jessamine, of which the fragrant flowers adorn the pagodas of Hindostan. The Dutch, who are so fond of gardens in Holland, have transferred that taste, where it can certainly be cultivated with more success, and indulge it to a great extent at their houses a little way from the city of Batavia; but still within that fenny district, concerning which an intelligent gentleman upon the spot used the strong expression, that the air was pestilential, and the water poisonous. Yet the country is every where so verdant, gay, and fertile; it is interspersed with such magnificent houses, gardens, avenues, canals, and draw-bridges; and is so formed in every respect to please, could health be preserved in it—that a youth coming just from sea, and enraptured with the beauty of every object he saw around him, but mindful of the danger there to life, could not help exclaiming, 'what an excellent habitation it would be for immortals!'

The most tolerable season here is from March or April to November; when the rains begin, and last the rest of the year. The sea breeze sets in about ten o'clock in the morning, and continues till four or five in the afternoon. It becomes then calm till seven or eight, when the land breeze commences, and continues at intervals till day-break, followed by a calm for the remaining hours of the 24. Fahrenheit's thermometer was, in Batavia road, during the Lion's remaining there, from 86° to 88°, and in the town from 88° to 92°; but its variations by no means corresponded to the sensations produced by the heat on the human frame; the latter being tempered by any motion of the air, which circumstance has little effect upon the thermometer. Nor are the animal sufferings here from heat to be measured by its intenseness at any given moment of the day, but by its persisting through the night; when, instead of diminishing, as it does in colder countries, sometimes 20 degrees, it keeps generally here within four or five of what it attains in the shade, when the sun is at its highest elevation.

The native Javanese derive, however, one advantage at least from an atmosphere not subject to the vicissitudes of temperature experienced in the northern parts of Europe, where diseases of the teeth are chiefly prevalent; as they are here entirely exempt from such complaints. Their habit of living chiefly on vegetable food, and of abstaining from fermented liquors, no doubt contributes to this exemption; yet such is the caprice of taste, that jet black is the favourite colour and standard of beauty for the teeth amongst them, comparing to monkeys those who keep them of the natural colour. They accordingly take care to paint, of the deepest black, all their teeth, except the two middle ones, which they cover with gold leaf. Whenever the paint or gilding is worn off, they are as attentive to replace it on the proper teeth, as the belles of Europe are to purify and whiten theirs.

We have mentioned the rich vegetation of the country and the gardens which the Dutch have planted. In these gardens or orchards they cultivate the nutmeg, the clove, the camphor, and the cinnamon trees, together with the pepper plant, which creeping like a vine, is supported on a living tree. It is a species of the pepper plant that affords the leaf called *betel*, chewed so universally by the southern Asiatics, and serving for the inclosure of a few slices or bits of the areca, from thence erroneously called the *betel nut*. The areca nut tree is among the smallest of the tribe of palms, but comes next in beauty to the mountain cabbage tree of the West Indies; the latter differing chiefly in its size and amazing height from the areca nut tree, the diameter of whose jointed trunk seldom exceeds four inches, or height 12 feet. But the symmetry of each is perfect; the columns of a temple cannot be more regular than the trunk, which rises without a branch, while the broad and spreading leaves which crown the top form the ornamented capital. The areca nut, when dried, has some similitude in form and taste to the common nutmeg, but is of a less size.

It would have been very extraordinary, and very culpable, in Sir George Staunton, and Dr Gillan physician to the embassy, if they had not, when on the spot, inquired into the truth of Foersch's account of the *upas* or poison-tree of Java (see *Poison Tree of Java*, Encycl.) But the most minute inquiries were made respecting it; and the result of them was, that no such tree is known at Batavia, and certainly does not exist where Foersch has planted it. It is indeed a common opinion at Batavia, that there exists in that country a vegetable poison, which, rubbed on the daggers of the Javanese, renders the slightest wounds incurable; though some European practitioners have of late asserted that they had cured persons stabbed by those weapons, but not without having taken the precaution of keeping the wound long open, and procuring a suppuration. One of the keepers of the medical garden at Batavia assured Dr Gillan, that a tree distilling a poisonous juice was in that collection, but that its qualities were kept secret from most people in the settlement, lest the knowledge of them should find its way to the slaves, who might be tempted to make an ill use of it. In the same medical garden, containing it seems hurtful as well as grateful substances, is found also the plant from whence is made the celebrated gout remedy, or moxa of Japan, mentioned in the works of Sir William Temple, and described in the Encyclopædia under the titles of Artemisia and Moxa.

The whole country abounds with esculent fruits, and, amongst others, with the mangosteen, which is ripe in March, and is considered as the most delicious of all fruits (see Garcinia, *Encycl.*) Pine apples are in Java planted not in gardens, but in large fields; and are carried like turnips in heaps upon carts to market, and sold for considerably less than a penny each, where money is cheaper than in England. It was a common practice to clean swords, or other instruments of steel or iron, by running them through pine apples, as containing the strongest and cheapest acid for dissolving the rust that covered them. Sugar sold for about five-pence a pound. All sorts of provisions were cheap, and the ships crews fed on fresh meat every day.

The serpents and noxious reptiles in Java have been mentioned elsewhere; but Sir George Staunton assures us, that not many accidents happen from them. Among the pagan Javanese, the crocodile, he says, is an object not

not only of fear, but alfo of religious veneration, to which offerings are made as to a deity. When a Javanefe feels himfelf difeafed, he will fometimes build a kind of coop, and fill it with fuch eatables as he thinks moft agreeable to the crocodiles. He places the coop upon the bank of the river or canal, in the perfect confidence that, by the means of fuch offerings, he will get rid of his complaints; and perfuaded, that if any perfon could prove fo wicked as to take away thofe viands, fuch perfon would draw upon himfelf the malady for the cure of which the offering was made. According to Sir George Staunton, Batavia road lies in 6° 10′ fouth lat. and 106° 51′ eaft long. from Greenwich.

BATH, a townfhip in Lincoln co. Diftrict of Maine, containing 949 inhabitants. It lies on the W. fide of Kennebeck River about 13 miles from Wifcaffet, 60 N. E. from Portland, 32 from Hallowell, 13 from Pownalboro', and 165 N. E. from Bofton. N. lat. 43. 49.—*Morse.*

Bath, a county of Virginia, about 60 miles in length, and 50 in breadth; bounded E. by the county of Augufta. It is noted for its medicinal fprings, called the *Hot* and *Warm* fprings, near the foot of Jackfon's Mountain, which fee.—*ib.*

Bath, a thriving town in Berkly co. Virginia, fituated at the foot of the Warm Spring Mountain. The fprings in the neighbourhood of this town, although lefs efficacious than the Warm Springs in Bath co. draw upwards of 1000 people here, during fummer, from various parts of the United States. The water is little more than milk-warm, and weakly impregnated with minerals. The country in the environs is agreeably diverfified with hills and valleys; the foil rich, and in good cultivation; 25 miles from Martinfburg, and 269 miles S. W. from Philadelphia.—*ib.*

Bath, a townfhip in Grafton co. N. Hampfhire, containing 493 inhabitants. It lies on the E. bank of Connecticut River 35 miles N. E. by N. from Dartmouth College, and 97 N. W. from Portfmouth.—*ib.*

Bath, or *Port Bath*, an ancient town in Hyde co. N. Carolina, on the N. fide of Tar River about 24 miles from Pamplico Sound, 61 S. by W. of Edenton, and is the port of entry on Tar River. It contains about 12 houfes, and is rather declining. N. lat. 35. 31. W. long. 77. 15.—*ib.*

Bath, a village in the eaftern parifh of St Thomas, in the Ifland of Jamaica, in the W. Indies. It has its rife and name from a famous hot fpring in its vicinity, faid to be highly efficacious in curing the dry belly-ache. The water is fulphureous, and flows out of a rocky mountain about a mile diftant; and is too hot to admit a hand being held in it.—*ib.*

Bath, a village in the co. of Renffalaer, New-York, pleafantly fituated on the eaft bank of Hudfon river, nearly oppofite the city of Albany, at the head of floop navigation. A mineral fpring has been difcovered here, faid to poffefs valuable qualities; and a commodious bathing-houfe has been erected, at a confiderable expenfe, containing hot, cold, and fhower baths. —*ib.*

BAY OF FUNDY, wafhes the fhores of the Britifh provinces of New-Brunfwick on the N. and Nova-Scotia on the E. and S. This bay is 12 leagues acrofs, from the Gut of Annapolis to St John's, the principal town of New-Brunfwick. The tides are very rapid in this bay, and rife at Annapolis Bafin about 30 feet; at the Bafin of Minas, which may be termed the N. arm of this bay, 40 feet; and at the head of Chignecto channel, an arm of this bay, the fpring tides rife 60 feet.—*ib.*

BAY OF ISLANDS, lies on the W. fide of Newfoundland Ifland in the gulf of St Lawrence. This bay is very extenfive, having 3 arms, by which feveral rivers empty into it. It has feveral iflands; the chief of which are called Harbor, Pearl, and Tweed. The centre of the bay lies in about 49. 5. N. lat. and 58. 15. W. long. from Greenwich.—*ib.*

BEAR *Grafs Creek*, a fmall creek on the eaftern fide of Ohio River, a few hundred yards N. of the town of Louifville, in Kentucky. This is the fpot where the intended canal is propofed to be cut to the upper fide of the *Rapids*. From the mouth of the creek, to the upper fide of the rapids, is not quite 2 miles. This would render the navigation of the Ohio fafe and eafy. The country on the fides of this creek, between Salt River and Kentucky River is beautiful and rich.—*ib.*

BEAUFORT, a feaport town in Carteret co. on the N. E. fide of Core Sound, and diftrict of Newbern, N. Carolina. It contains about 20 houfes, a court-houfe and gaol, and the county courts are held here. It is 55 miles S. by E. of Newbern, and about 27 from Cape Lookout. N. lat. 34. 47.—*ib.*

Beaufort, the chief town of Beaufort diftrict, S. Carolina, is fituated on the ifland of Port Royal, at the mouth of Coofawhatchie River. The courts which were formerly held here, are now removed to the town of Coofawhatchie, on the above fmall river. Beaufort is a little pleafant town, of about 60 houfes, and 200 inhabitants; who are diftinguifhed for their hofpitality and politenefs. It has a fine harbor, and bids fair to become a confiderable town. It ufed to be a ftation for the Britifh fquadron when in their poffeffion. Beaufort is fituated 26 miles from Purifburg, and 73 from Charlefton, to the S. W. noted for its healthy fituation. N. lat. 32. 26. W. long. 80. 55.—*ib.*

Beaufort *Diftrict*, in the lower country of S. Carolina, lies on the fea coaft, between Combahee and Savannah rivers. It is 69 miles in length, and 37 in breadth, and is divided into 4 parifhes, viz. St Helena, St Luke, Prince William, and St Peter, which contain 18,753 inhabitants; of whom only 4346 are whites. The northern part of this diftrict abounds with large forefts of cyprefs; the lands, however, are fit for raifing rice, indigo, &c. It fends 12 reprefentatives and 4 fenators to the ftate legiflature; each parifh fending an equal number. Amount of taxes £3,022-2-11 fter.—*ib.*

BEAVER *Creek*, runs into Lake Erie, at its E. end; about 7 miles S. E. from Fort Erie.—*ib.*

BEAVERS *Town*, at *Tufkarawas*, lies between Margaret's Creek, an upper N. W. branch of Mufkingum River and the N. branch of that river; at the head of which N. branch there is only a mile's portage to Cayahoga River. Beavers Town lies about 85 miles N. W. from Pittfburg. A little below this a fort was erected in 1764.—*ib.*

BECKET, a townfhip in Berkfhire co. Maffachufetts, containing 751 inhabitants. It is 10 miles E. of

Stockbridge,

Stockbridge, 17 from Lenox, and 130 W. from Boston.—*ib.*

BEDFORD, a townſhip in Hillſborough co. New-Hampſhire, which was incorporated in 1750, and contains 898 inhabitants. It lies on the W. bank of Merrimack River 56 miles W. of Portſmouth.—*ib.*

Bedford, a townſhip in Middleſex co. Maſſachuſetts, containing 523 inhabitants; 13 miles northerly from Boſton.—*ib.*

Bedford, New, is a flouriſhing town in Briſtol co. in the ſame ſtate, containing 3313 inhabitants; 58 miles ſouthward of Boſton. It lies at the head of navigation on Acuſhnet River. Lat. 40. 41. N. long. 70. 52. W. from Greenwich.—*ib.*

Bedford, a townſhip in W. Cheſter co. New York, containing 2470 inhabitants, including 38 ſlaves. It lies contiguous to Connecticut, 12 miles N. from Long-Iſland Sound, and 35 from the city of New-York. In the ſtate cenſus of 1796, there appears to be 302 electors.—*ib.*

Bedford, a town on the W. end of Long Iſland New-York, 4 miles N. W. from Jamaica Bay, and 6 E. from the city of New-York.—*ib.*

Bedford, *Co.* in Pennſylvania, lies on Juniatta River; has part of the ſtate of Maryland on the S. and Huntingdon co. N. and N. E. It contains 13,124 inhabitants, including 46 ſlaves; and has ½ of its lands ſettled, and is divided into 9 townſhips.

Its chief town, Bedford, lies on the S. ſide of the Rayſtown branch of the ſame river; 25 miles eaſtward of Berlin, and 210 W. of Philadelphia. It is regularly laid out; and the inhabitants, who live in 41 log houſes and 9 of ſtone, have water conveyed in wooden pipes to a reſervoir in the middle of the town. They have a ſtone gaol; the market-houſe, court-houſe, and record office, are built of brick. Bedford was incorporated in 1795, and their charter is ſimilar to that of Cheſter. N. lat. 40, W. long. 78. 50.—*ib.*

BEDMINSTER, in Somerſet co. New-Jerſey, is a townſhip containing 1197 inhabitants, including 169 ſlaves.—*ib.*

BEEKMAN, a conſiderable townſhip in Ducheſs co. New-York, containing 3597 inhabitants, including 106 ſlaves. In the ſtate cenſus of 1796 there appears to be 502 electors in this townſhip.—*ib.*

BEER is a liquor ſo palatable to the natives of Britain, and, when properly made, ſo wholeſome, eſpecially in long voyages at ſea, that Mr Thornton of Eaſt Smithfield obtained a patent, dated April 15, 1778, for inventing a method of reducing *malt* and *hops* to an eſſence or extract, from which beer may be made anywhere, either at ſea or in diſtant countries. Though we do not perceive any great degree of ingenuity diſplayed in this invention, yet as the account of it is ſhort, we ſhall lay it before our readers.

His method then of preparing an eſſence or extract of malt and hops is, by the tranſmitted heat of compreſſed vapour of boiling water, and a proper apparatus for that purpoſe. This apparatus may be made of iron, tin, or copper: it conſiſts of a boiler of any dimenſions, a double veſſel, and conducting tubes. The double veſſel conſiſts of one veſſel placed within another, and fitted tight at their rims. The upper veſſel forms the upper part of the under veſſel, and contains the liquor to be evaporated. The under veſſel is everywhere incloſed, except at an aperture communicating with the boiler, and at another aperture communicating with the conducting tubes; and is conſtructed ſo as not to allow any part of the vapour condenſed into drops within it to eſcape, except back again into the boiler: it is not ſo extenſive as to act as a common refrigeratory, and yet is capacious enough to prevent the liquor boiling over. The aperture communicating with the boiler is large enough to freely admit the vapour from the boiler into the under veſſel; and the aperture communicating with the conducting tubes is of a proper ſize to allow of the vapour in the under veſſel being compreſſed, to a degree capable of tranſmitting to the liquor to be evaporated a proper heat, and at the ſame time to ſerve as a paſſage for more heat than is neceſſary to keep up that degree of compreſſion. The conducting tubes are to convey this ſuperfluous heat or vapour, to be uſed for farther purpoſes, or immediately out of the building.

BEETLE, an inſect deſcribed in the Encyclopædia under the name given to it by naturaliſts, Scarabæus. Since that article was publiſhed, we have met with an account of a nondeſcript ſpecies, which is furniſhed with very ſingular armour for its own defence. It was brought to M. Vaillant in the interior parts of Africa by a Nimiqua woman, and is by him called a ſuperb beetle not to be found in any cabinet of Europe. "While I was examining this beautiful inſect (ſays he) with attention, I felt my face ſuddenly wetted by a cauſtic liquor, of a very ſtrong alkaline ſmell. The ſprinkling was accompanied by a ſort of exploſion, loud enough to be heard at ſome diſtance. Unfortunately ſome of the liquor entered one of my eyes, and occaſioned ſuch inſupportable pain, that I thought I ſhould have loſt the ſight of it. I was obliged to keep it covered for ſeveral days, and bathe it from time to time with milk. In every part of my face that the alkaline liquor had touched, I felt the pain of a burn; and everywhere the ſkin changed to a deep brown, which wore out only by degrees and a long time after. This will not be ſurpriſing to many, who already are acquainted with the ſame property in ſeveral inſects of the ſame genus; for inſtance, in that beautiful golden-green bupreſtis, which is ſo common in our kitchen-gardens in Europe: but as the inſect of which I am here ſpeaking is much larger, and inhabits a very hot country, it is natural that the effect produced by it ſhould be more ſtriking; tho' the liquor which our golden bupreſtis ejects at its enemy occaſions a very ſenſible ſmart, and its ſmell is conſiderably pungent."

The naturaliſts Dorci and Olivier have given, in their Entomology, the figure of this African inſect, which our author communicated to them, but they have given it erroneouſly. The human face, obſervable on its anterior corcelet in their figure, does not exiſt in nature; but M. Vaillant having given no figure of it himſelf, we cannot gratify our readers with a correct repreſentation.

BEGAH, a land meaſure in Bengal, about one-third of an Engliſh acre.

BEHADER *(Valiant)*, a title of honour conferred by the Mogul emperors upon either Mahomedans or Hindoos, and placed after their name or other title.

BEHEM (Martin), though hitherto little talked of, was one of the moſt enterpriſing men that ever lived, and

Behem.

and deserves to have his name transmitted with reverence to the latest posterity. Born at Nuremberg, an Imperial city in the circle of Franconia, of a noble family not yet extinct, he had the best education which the darkness of that age would permit him to have; and the studies to which from his infancy he was most addicted, were those of geography, astronomy, and navigation. As he advanced in life, he often thought of the existence of the antipodes and of a western continent, of which he was ambitious to make the discovery.

Filled with this great idea, in 1459 he paid a visit to Isabella, daughter of John I. king of Portugal, at that time regent of the duchy of Burgundy and Flanders; and having informed her of his designs, he procured a vessel, in which, sailing westward, he was the first European who is known to have landed on the island of Fayal. He there established in 1460 a colony of Flemings, whose descendants yet exist in the Azores, which were for some time called the Flemish Islands. This circumstance is proved, not only by the writings of contemporary authors, but also by the manuscripts preserved in the records of Nuremberg; from the Latin of which the following is translated: "Martin Behem tendered his services to the daughter of John King of Lusitania, who reigned after the death of Philip of Burgundy, surnamed the *Good;* and from her procured a ship, by means of which, having sailed beyond all the then known limits of the Western Ocean, he was the first who in the memory of man discovered the island of Fayal, abounding with beech trees, which the people of Lusitania call *faye;* whence it derived its name. After this he discovered the neighbouring islands, called by one general name the *Azores*, from the multitude of hawks which build their nests there (for the Lusitanians use this term for hawks, and the French too use the word *essos* or *esores* in their pursuit of this game); and left colonies of the Flemish on them, when they began to be called Flemish Islands (A)."

After having obtained from the regent a grant of Fayal, and resided there about twenty years, Behem applied in 1484 (eight years before Columbus's expedition) to John II. king of Portugal, to procure the means of undertaking a great expedition towards the south-west. This prince gave him some ships, with which he discovered that part of America which is now called Brazil; and he even sailed to the Straits of Magellan, or to the country of some savage tribes whom he called Patagonians, from the extremities of their bodies being covered with a skin more like a bear's paws than human hands and feet.

A fact so little known, and apparently so derogatory to the fame of Columbus, ought not to be admitted without sufficient proof; but the proofs which have been urged in support of its authenticity are such as cannot be controverted. They are not only the letters of Behem himself, written in 1486, and preserved in the archives of Nuremberg, but likewise the public records of that city; in which we read that "Martin Behem, traversing the Atlantic Ocean for several years, examined the American islands, and discovered the strait which bears the name of Magellan before either Christopher Columbus or Magellan sailed those seas; whence he mathematically delineated, on a geographical chart, for the king of Lusitania, the situation of the coast around every part of that famous and renowned strait long before Magellan thought of his expedition."

This wonderful discovery has not escaped the notice of contemporary writers. The following passage is translated from the Latin chronicle of Hartman Schedl: "In the year 1485, John II. king of Portugal, a man of a magnanimous spirit, furnished some galleys with provisions, and sent them to the southward, beyond the Straits of Gibraltar. He gave the command of this squadron to James Canus, a Portuguese, and Martin Behem, a German of Nuremberg in Upper Germany, descended of the family of Bonna: a man very well acquainted with the situation of the globe; blessed with a constitution able to bear the fatigues of the sea; and who, by actual experiments and long sailing, had made himself perfectly master with regard to the longitudes and latitudes of Ptolemy in the west. These two, by the bounty of Heaven, coasting along the Southern Ocean, and having crossed the equator, got into the other hemisphere, where, facing to the eastward, their shadows projected towards the south and right hand. Thus, by their industry, they have opened to us another world hitherto unknown, and for many years attempted by none but the Genoese, and by them in vain. Having finished this cruize in the space of 26 months, they returned to Portugal with the loss of many of their seamen by the violence of the climate."

Besides this evidence of the first discovery of America having been made by Behem, we find the following particulars in the remarks made by Petrus Mateus on the canon law, two years before the expedition of Columbus: "*Primæ navigationes*, &c. The first Christian voyages to the newly discovered islands became frequent under the reign of Henry, son of John, king of Lusitania. After his death Alphonsus V. prosecuted the design; and John, who succeeded him, followed the plan of Alphonsus, by the assistance of Martin Bohem, a very skilful navigator; so that in a short time the name of Lusitania became famous over the whole world." Cellarius, one of the most learned men of his age, says expressly, "*Behcimcus non modo*, &c. Bœhm did not think it enough to survey the island of Fayal, which he first discovered, or the other adjacent islands which the Lusitanians call *Azores*, and we, after the example of Bœhm's companions, call *Flemish* islands, but advanced still farther and farther south, until he arrived at the remotest strait, through which Ferdinand Magellan, following

(A) Although this record is contrary to the generally received opinion, that the Azores were discovered by Gonsalva Velho, a Portuguese, yet its authenticity seems unquestionable. It is confirmed not only by several contemporary writers, and by Wagenseil, one of the most learned men of the last century, but likewise by a note written on parchment in the German language, and sent from Nuremberg, a few years ago, to M. Otto, who was then investigating the discovery of America. The note contained, with other things, the following facts: "Martin Beham, Esq; son of Mr Martin Beham of Scoperin, lived in the reign of John II. king of Portugal, in an island which he discovered, and called the island of *Fayal*, one of the Azores, lying in the Western Ocean."

Behem.

following his track, afterwards failed, and called it after his own name."

All thefe quotations, which cannot be thought tedious, fince they ferve to prove a fact almoft unknown, feem to demonftrate, that the firft difcovery of America is due to the Portuguefe and not to the Spaniards; and that the chief merit belongs to a German aftronomer. The expedition of Ferdinand Magellan, which did not take place before the year 1519, arofe from the following fortunate circumftance: This perfon, being in the apartment of the king of Portugal, faw there a chart of the coaft of America drawn by Behem, and at once conceived the bold project of following the fteps of this great navigator. Jerome Benzon, who publifhed a defcription of America in 1550, fpeaks of this chart; a copy of which, fent by Behem himfelf, is preferved in the archives of Nuremberg. The celebrated aftronomer Riccioli, though an Italian, yet does not feem willing to give his countryman the honour of this important difcovery. In his *Geographia Reformata*, book. iii. p. 90. he fays, "Chriftopher Columbus never thought of an expedition to the Weft Indies until his arrival in the ifland of Madeira, where, amufing himfelf in forming and delineating geographical charts, he obtained information from Martin Bœhm, or, as the Spaniards fay, from Alphonfus Sanchez de Huelva a pilot, who had chanced to fall in with the ifland afterwards called *Dominica*." And in another place: "Let Bœhm and Columbus have each their praife; they were both excellent navigators; but Columbus would never have thought of his expedition to America, had not Bœhm gone there before him. His name is not fo much celebrated as that of Columbus, Americus, or Magellan, although he is fuperior to them all."

That Behem rendered fome very important fervices to the crown of Portugal, is put beyond all controverfy by the recompence beftowed on him by King John; of which the following account has been given to the public from the archives of Nuremberg. "In the year 1485, on the 18th of Feb. in Portugal, in the city of Allafavas, and in the church of St Salvador, after the mafs, Martin Behem of Nuremberg was made a knight, by the hands of the moft puiffant Lord John II. king of Portugal, Algarve, Africa, and Guinea; and his chief fquire was the king himfelf, who put the fword in his belt; and the Duke of Begia was his fecond fquire, who put on his right fpur; and his third fquire was Count Chriftopher de Mela, the king's coufin, who put on his left fpur; and his fourth fquire was Count Martini Marbarinis, who put on his iron helmet; and the king himfelf gave him the blow on the fhoulder, which was done in the prefence of all the princes, lords, and knights of the kingdom; and he efpoufed the daughter of a great lord, in confideration of the important fervices he had performed; and he was made governor of the ifland of Fayal."

Thefe marks of diftinction, conferred on a ftranger, could not be meant as a recompenfe for the difcovery of the Azores, which was made twenty years before, but as a reward for the difcovery of Congo, from whence the Chevalier Behem had brought gold and different kinds of precious wares. This difcovery made much greater impreffion than that of a weftern world made at the fame time, but which neither increafed the wealth of the royal treafury, nor fatisfied the avarice of the merchants.

In 1492 the Chevalier Behem, crowned with honours and riches, undertook a journey to Nuremberg, to vifit his native country and his family. He there made a terreftrial globe, which is looked on as a mafterpiece for that time, and which is ftill preferved in the library of that city. The outline of his difcoveries may there be feen, under the name of weftern lands; and from their fituation it cannot be doubted that they are the prefent coafts of Brazil, and the environs of the Straits of Magellan. This globe was made in the fame year that Columbus fet out on his expedition; therefore it is impoffible that Behem could have profited by the works of that navigator, who befides went a much more northerly courfe.

After having performed feveral other interefting voyages, the Chevelier Behem died at Lifbon in July 1506, regretted by every one, but leaving behind him no other work than the globe and chart which we have juft been fpeaking of. The globe is made from the writings of Ptolemy, Pliny, Strabo, and efpecially from the account of Mark Paul, the Venetian, a celebrated traveller of the 13th century; and of John Mandeville, an Englifhman, who, about the middle of the 14th century, publifhed an account of a journey of 33 years in Africa and Afia. He has alfo added the important difcoveries made by himfelf on the coafts of Africa and America.

From thefe circumftantial accounts, but very lately brought to light, there can be little doubt, we think, but that America was difcovered by Martin Behem. Dr Robertfon is indeed of a different opinion: but great as we willingly acknowledge his authority to be, we may differ from him without prefumption, fince he had it not in his power to confult the German documents to which we have appealed, and has himfelf advanced facts not eafily to be reconciled to his own opinion. He allows that Behem was very intimate with Chriftopher Columbus; that he was the greateft geographer of his time, and fcholar of the celebrated John Müller, or Regiomontanus; that he had difcovered, in 1483, the kingdom of Congo, upon the coaft of Africa; that he made a globe which Magellan made ufe of; that he drew a map at Nuremberg, containing the particulars of his difcoveries; and that he placed in this chart land which is found to be in the latitude of Guiana. He adds indeed, without proof, that this land was a fabulous ifland; but if authentic records are to give place to bare affertion, there is an end of all hiftorical evidence. If Behem took for an ifland the firft land which he difcovered, it was a miftake furely not fo grofs as to furnifh grounds for queftioning his veracity, or for withholding from him for ever that juftice which has been fo long delayed.

But this very delay will by fome be thought a powerful objection to the truth of Behem's claim to the difcovery of America; for if it was really difcovered by him, why did not he leave behind him fome writing to confirm the difcovery to himfelf? and why did not the court of Portugal, fo jealous of the difcovery of the new world, proteft againft the exclufive claim of the Spaniards?

To thefe objections we may reply, that, however plaufible they may at firft appear, they do not in the

fmalleft

smallest degree invalidate the positive evidence which we have urged for the Chevalier Behem's being the real discoverer of the new world; for it would surely be very absurd to oppose the *difficulty of assigning motives* for *certain* actions performed at a remote period, to the *reality* of *other* actions for which we have the testimony of a cloud of contemporary witnesses. Supposing it were true, therefore, that Behem had left behind him no writing claiming to himself the discovery of any part of the continent of America, the only inference which could be drawn from his silence would be, either that he was a man of great modesty, or that his mind was intent only on the acquisition of knowledge to himself, without feeling the usual impulse to communicate that knowledge to others. But it is not true that he has left behind him no claim of this discovery to himself. The letters to which we have appealed, and which are preserved in the archives of Nuremberg, together with the globe and map, which he certainly made, furnish as complete a confirmation of his claim as could have been furnished by the most elegant account of his voyages.

For the silence of the Portuguese, many reasons might be assigned. The discoveries of Columbus were made so much farther north than those of Behem, that, in an age when geographical knowledge was so very limited, both Spaniards and Portuguese might very naturally believe that the country discovered by the former of these navigators had no connection with that discovered by the latter. At any rate, the Portuguese, whose discoveries proceeded from avarice, were satisfied with scraping together gold wherever they could find it; and finding it in Africa, they thought not of searching for it in a more distant region, till the success of the Spaniards shewed them their mistake.

One thing more is worthy of attention. The long stay of Columbus at Madeira makes his interview with Behem more than probable. It is impossible that he should have neglected seeing a man so interesting, and who could give him every kind of information for the execution of the plan which he had formed. The mariners who accompanied the Chevalier Behem might also have spread reports at Madeira and the Azores concerning the discovery of which they had been witnesses. What ought to confirm us in this is, that Mariana says himself (book xxvi. chap. iii.), that a certain vessel going to Africa, was thrown by a gale of wind upon certain unknown lands; and that the sailors at their return to Madeira had communicated to Christopher Columbus the circumstances of their voyage. All authors agree that this learned man had some information respecting the western shores; but they speak in a very vague manner. The expedition of the Chevalier Behem explains the mystery (B).

BEHRING's *Bay*, on the N. W. coast of N. America, is separated from Admiralty Bay, on the northward, by a point of land; and lies N. W. from Cross Sound.—*Morse*.

BEHRING's *Straits*, separate Asia from America, are so called from the Russian navigator, Capt. Behring, who with Ishirikow, sailed from Kamptschatka, in Siberia, on the Asiatic coast, in quest of the New World, in a quarter where it had, perhaps, never been approached. They both discovered land within a few degrees of the N. W. coast of America. But the more recent discoveries of Capt. Cook, and his successor, Clarke, have confirmed the near approximation of the two continents. Cape Prince of Wales is the most westerly point of the American continent, hitherto known. It is situated in N. lat. 65. 46. E. long. 191. 45. and is 39 miles distant from the eastern coast of Asia.

The sea, from the S. of Behring's Straits, to the crescent of isles between Asia and America, is very shallow. It deepens from these straits (as the British seas do from Dover) till soundings are lost in the Pacific Ocean; but that does not take place but to the S. of the isles. Between them and the straits is an increase from 12 to 54 fathoms, except only off St Thaddeus Noss, where there is a channel of greater depth. From the volcanic disposition, it has been judged probable, not only that there was a separation of the continents at these straits, but that the whole space from the isles to that small opening had once been dry land; and that the fury of the watery element actuated by that of fire, had, in very remote times, subverted and overwhelmed the tract, and left the islands to serve as monumental fragments.

The famous Japanese map places some islands seemingly within these straits, on which is bestowed the title of *Ya Zue*, or the kingdom of the dwarfs. This gives some reason to suppose that America was not unknown to the Japanese; and that they had, as is mentioned by Kæmpfer, and Charlevoix, made voyages of discovery; and, according to the last, actually wintered upon the continent, where probably meeting with the Esquimaux, they might, in comparison of themselves, and justly, distinguish them by the name of dwarfs.—*ib.*

BEKIA, or *Becouya*, or *Boquio*, a small British island among the Granadillas; 55 miles N. E. of Granada, and 65 leagues from Barbadoes. It was called Little Martinico by the French, and has a safe harbour from all winds; but no fresh water. It is only frequented by those who catch turtle. The soil produces wild cotton, and plenty of water melons. —*ib.*

BELCHER, a township in Hampshire co. Massachusetts, containing 1485 inhabitants, who subsist chiefly by farming. It lies 12 miles E. of Hadley, and 85 W. of Boston.—*ib.*

BELFAST, a township and bay in Hancock co. District of Maine, both situated in what is called the Waldo Patent, at the mouth of Penobscot River and on its western side; 38 miles N. E. by E. from Hallowell, and 246 N. E. from Boston. The town contains 245 inhabitants. The Bay, on the N. western part of which the town stands, runs up into the land by three short arms. Islesborough Island lies in the middle of it, and forms two channels leading to the mouth of Penobscot river.—*ib.*

(B) For the greater part of this memoir we are indebted to M. Otto's paper on the discovery of America, published first in the second volume of the American Transactions, and afterwards by Nicholson in N° II. and III. of his Journal.

Bellaire || Benson.

BELLAIRE, a post-town near the centre of Harford co. Maryland, and the chief of the county. It contains a court-house and gaol, and is thinly inhabited; distant from Harford, 6 miles, N. W; 22 N. E. from Baltimore, and 86 W. S. W. from Philadelphia. —*Morse.*

BELLINGHAM, a small farming township in Norfolk co. Massachusetts, containing 735 inhabitants, 20 miles northerly from Providence, and 34 southerly from Boston.—*ib.*

BELLS *Mill*, a settlement in N. Carolina, near the Moravian settlements, at the source of Deep river the N. western-most branch of the N. W. branch of Cape Fear, and about 50 miles W. of Hillsborough.—*ib.*

BELPRE, a post-town and small settlement in the territory N. W. of the Ohio, on the N. W. bank of Ohio river between the Hockhocking and Muskingum rivers and opposite the mouth of the Little Kanhaway; about 14 miles below Marietta, and 480 S. W. by W. from Philadelphia.—*ib.*

BELVIDERE, a new township in Franklin co. Vermont.——Also a village in New-Jersey, in Sussex co. situated on Delaware river at the mouth of Pequest river and 11 miles above Easton, in Pennsylvania.—*ib.*

BENNINGTON, a county in the S. W. corner of Vermont, having Windham co. on the E. and the state of N. York on the W; into which state it sends Batten Kill and Hoosack rivers, which both rise here, and fall into Hudson river 14 miles apart: Rutland co. lies on the N. and the state of Massachusetts on the S. It contains 19 townships, of which Bennington and Manchester are the chief. It has 12,254 inhabitants, including 16 slaves. The mountains here furnish iron ore in abundance, and employ already, a furnace and two forges.—*ib.*

Bennington, the shire town of the above county, and the largest town in the state of Vermont, having about 160 houses, in the compact part of the town, is situated at the foot of the Great Mountain, near the S. W. corner of the state, 24 miles easterly from the junction of Hudson and Mohawk rivers, and about 52 from the S. end of Lake Champlain, at the confluence of the E. and S. bays; and lies 55 miles from Rutland; 202 miles N. easterly from New-York; and 300 in the same direction from Philadelphia. N. lat. 42. 42. W. long. 74. 10. Bennington has several elegant buildings. Its public edifices are a congregational church, state house and gaol. It is the oldest town in the state, having been first settled in 1764, and is in a flourishing condition, containing 2,400 inhabitants. Within the township is Mount Anthony, which rises very high in a conical form.

Two famous battles were fought in or near this town, in one day, Aug. 16, 1777, in which Col. Stark gained great fame. The British lost 4 brass field pieces, and other military stores; and besides those slain, 700 were taken prisoners. The killed and wounded of the Americans were about 100 men. This defeat contributed, in a great measure, to the subsequent surrender of Gen. Burgoyne's army.—*ib.*

BENSON, the N. westernmost township in Rutland co. Vermont, is situated on the E. side of Lake Champlain; 57 miles N. N. W. of Bennington, and has 658 inhabitants. Hubberton river passes through Benson in its way to East Bay. Cockburne's Creek, which feeds the same bay, rises here.—*ib.*

Bereans.

BEREANS, in ancient church history, the inhabitants of Berea. They are highly commended in Scripture for their ready reception of the gospel, upon a fair and impartial examination of its agreement with the Old Testament prophecies. Sopater, a Berean, attended the apostle Paul to Asia. Acts xvii. 10—13. and xx. 4.

Bereans, in modern church history, a sect of Protestant dissenters from the church of Scotland, who take their title from, and profess to follow, the example of the ancient Bereans, in building their system of faith and practice upon the Scriptures alone, without regard to any human authority whatever.

Doctrines.

The Bereans agree with the great majority of Christians, both Protestants and Catholics, respecting the doctrine of the Trinity, which they hold as a fundamental article of the Christian faith; and they also agree in a great measure with the *professed* principles of both our established churches respecting predestination and election, though they allege that these doctrines are not consistently taught in either church. But they differ from the majority of all sects of Christians in various other important particulars. Such as,

1. Respecting our knowledge of the Deity. Upon this subject, they say, that the majority of professed Christians stumble at the very threshold of revelation; and, by admitting the doctrine of natural religion, natural conscience, natural notices, &c. not founded upon revelation, or derived from it by tradition, they give up the cause of Christianity at once to the infidels; who may justly argue, as Mr Paine in fact does in his Age of Reason, that there is no occasion for any revelation or word of God, if man can discover his nature and perfections from his works alone. But this, the Bereans argue, is beyond the natural powers of human reason; and therefore our knowledge of God is from revelation alone; and that without revelation man would never have entertained an idea of his existence.

2. With regard to faith in Christ, and assurance of salvation through his merits, they differ from almost all other sects whatsoever. These they reckon *inseparable*, or rather the *same*; because, they argue, God hath expressly declared, "He that believeth shall be saved;" and therefore it is not only absurd, but impious, and in a manner calling God a liar, for a man to say, "*I believe* the Gospel, but *have doubts* nevertheless of my own salvation." With regard to the various distinctions and definitions that have been given of different kinds of faith, they argue, that "there is nothing incomprehensible or obscure in the meaning of this word as used in Scripture; but that as faith, when applied to human testimony, signifies neither more nor less than the mere simple belief of that testimony as true, upon the authority of the testifier; so, when applied to the testimony of God, it signifies precisely the belief of his testimony, and resting upon his veracity alone, without any kind of collateral support from concurrence of any other evidence or testimony whatever." And they insist, that as this faith is the gift of God alone, so the person to whom it is given is as conscious of possessing it, as the being to whom God gives life is of being alive; and therefore he entertains no doubts either of this faith or his consequent salvation through the merits of Christ, who

Bereans.

who died and rose again for that purpose. In a word, they argue, that the Gospel would not be what it is held forth to be, "glad tidings of great joy," if it did not bring full personal assurance of eternal salvation to the believer: which assurance, they insist, "is the present infallible privilege and portion of every individual believer of the Gospel." These definitions of faith, and its inseparable concomitant assurance, they prove by a variety of texts, which our room permits us not to quote.

3. Consistently with the above definition of faith, they say, that the sin against the Holy Ghost, which has alarmed and puzzled so many in all ages, is nothing else but *unbelief;* and that the expression, that "it shall not be forgiven, neither in *this world* nor that which is to come," means only, that a person dying in infidelity would not be forgiven, neither under the former dispensation by Moses (the then *present* dispensation, kingdom, or government of God), nor under the Gospel dispensation, which, in respect of the Mosaic, was a kind of future world or kingdom to come.

4. The Bereans interpret a great part of the Old Testament prophecies, and in particular the whole of the Psalms, excepting such as are merely historical or lauditory, to be typical or prophetical of Jesus Christ, his sufferings, atonement, mediation and kingdom: and they esteem it a gross perversion of these Psalms and prophecies to apply them to the experiences of private Christians. In proof of this, they not only urge the words of the apostle, that "no prophecy is of any private interpretation," but they insist that the whole of the quotations from the ancient prophecies in the New Testament, and particularly those from the Psalms, are expressly applied to Christ. In this opinion many other classes of Protestants agree with them.

5. Of the absolute all superintending sovereignty of the Almighty, the Bereans entertain the highest ideas, as well as of the uninterrupted exertion thereof over all works in heaven, earth, and hell, however unsearchable by his creatures. "A God without election (they argue), or choice in all his works, is a god without existence—a mere idol—a non-entity. And to deny God's election, purpose, and express will in all his works, is to make him inferior to ourselves." For farther particulars respecting the Berean doctrines, we must refer the reader to the works of Messrs Barclay, Nicol, Brookshank, &c.

Origin.

The Bereans first assembled as a separate society of Christians in the city of Edinburgh in autumn 1773, and soon after in the parish of Fettercairn. The opponents of the Berean doctrines allege, that this new system of faith would never have been heard of, had not Mr Barclay, the founder of it, been disappointed of a settlement in the church of Scotland. A respectable clergyman of the established church has even hinted something to this purpose in Sir John Sinclair's Statistical Account, Vol. IX. p. 599. But the Bereans, in answer to this charge, appeal not only to Mr Barclay's doctrine, uniformly preached in the church of Fettercairn, and many other places in that neighbourhood, for fourteen years before that benefice became vacant; but likewise to two different treatises, containing the same doctrines, published by him about ten or twelve years before that period. They admit, indeed, that, previous to May 1773, when the general assembly, by sustaining the king's presentation in favour of Mr Foote, excluded Mr Barclay from succeeding to the church of Fettercairn (notwithstanding the almost unanimous desire of the parishioners), the Bereans had not left the established church, or attempted to erect themselves into a distinct society; but they add, that this was by no means necessary on their part, until by the assembly's decision they were in danger of being not only deprived of his instructions, but of being scattered as sheep without a shepherd. And they add, that it was Mr Barclay's open and public avowal, both from the pulpit and the press, of those peculiar sentiments which now distinguish the Bereans, that was the first and principal, if not the only, cause of the opposition set on foot against his settlement in Fettercairn.

Practice.

Having thus given a concise view of the origin and distinguishing doctrines of Bereanism, it only remains to mention a few particulars relative to the practice of the Bereans as a Christian society. Infant baptism they consider as a divine ordinance instituted in the room of circumcision; and they think it absurd to suppose that infants, who all agree are admissible to the kingdom of God in heaven, should nevertheless be incapable of being admitted into His visible church on earth. They commemorate the Lord's supper in general once a month; but as the words of the institution fix no particular period, they sometimes celebrate it oftener, and sometimes at more distant periods, as may suit their general convenience. In observing this ordinance, they follow the primitive apostolic plan, without any previous days of fasting or preparation; as they apprehend that such human institutions only tend to make an idol of the ordinance, and to lead people to entertain erroneous ideas of its superior solemnity and importance. Equal and universal holiness in all manner of conversation, they recommend at all times, as well as at the table of the Lord. They meet every Lord's day for the purpose of preaching, praying, and exhortation to love and good works. With regard to the admission and exclusion of members, their method is very simple. When any person, after hearing the Berean doctrines, professes his belief and assurance of the truths of the Gospel, and desires to be admitted into their communion, he is cheerfully received upon his profession, whatever may have been his former manner of life. But if such an one should afterwards draw back from his good profession or practice, they first admonish him; and if that has no effect, they leave him to himself. They do not think that they have any power to deliver up a backsliding brother to Satan. That text and other similar passages, such as, "Whatsoever ye shall bind on earth shall be bound in heaven," &c. they consider as restricted to the apostles and to the inspired testimony alone, and not to be extended to any church on earth, or any number of churches or of Christians, whether deciding by a majority of votes or by unanimous voices. Neither do they think themselves authorised, as a Christian church, to enquire into each others political opinions, any more than to examine into each others notions of philosophy. They both recommend and practise, as Christian duties, submission to lawful authority; but they do not think that a man, by becoming a Christian, or joining their society, is under any obligation, by the rules of the Gospel, to renounce his rights of private judgment upon matters of public or private importance. Upon all

Bereans ‖ Berkenhout. such subjects they allow each other to think and act as each may see it his duty. And they require nothing more of their members than a uniform and steady profession of the apostolic faith, and a suitable walk and conversation. With regard to feet-washing and the like practices, which some other sects of Christians consider as duties, the Bereans are of opinion that they are by no means obligatory. They argue, that the example given by our Saviour of washing the feet of his disciples was not an institution of an ordinance, but merely a familiar instance, taken from the custom of the country, and adopted by our Lord on that occasion, to teach his followers that they ought at all times to be ready to perform even the meanest offices of kindness to each other.

Present state. It may not be improper to add to the above delineation of the principles and practice of the Bereans, that their doctrine has found converts in various places of Scotland, England, and America, and that they have congregations in Edinburgh, Glasgow, Paisley, Stirling, Crieff, Dundee, Arbroath, Montrose, Fettercairn, Aberdeen, and other towns in Scotland; as well as in London and various places in England; not to add Pennsylvania, the Carolinas, and other States in America.

The above account of the doctrines, origin, practice, and present state of this society, has been given to us by the founder himself.

BERGEN *Co.* in New-Jersey, on Hudson river, lies opposite New-York, on the E. and was first planted by the Dutch, from New-York. It contains 6 townships, of which the chief are Bergen and Hackinsack, and 12,601 inhabitants, including 2301 slaves. Here are 7 Dutch Calvinist churches, and 2 of Dutch Lutherans. There is a copper mine here, which when worked by the Schuylers (to whom it belonged) was considerably productive; but it has been neglected for many years.

It is a mountainous, rough and hilly county, 30 miles long, and 25 broad. It forms part of the E. and northern end of the state; and its N. W. extremity meets the N. E. part of Sussex co.; so that these two counties embosom Morris and Essex counties, except on the S. W. and form the whole breadth of the state in that quarter.—*Morse.*

BERKENHOUT (Dr John), was about the year 1730 born at Leeds in Yorkshire, and educated at the grammar school in that town. His father, who was a merchant, and a native of Holland, intended him for trade; and with that view sent him at an early age to Germany, in order to learn foreign languages. After continuing a few years in that country, he made the tour of Europe in company with one or more English noblemen. On their return to Germany they visited Berlin, where Mr Berkenhout met with a near relation of his father's, the Baron de Bielfeldt, a nobleman then in high estimation with Frederick the Great king of Prussia; distinguished as one of the founders of the Royal Academy of Sciences at Berlin, and universally known as a politician and a man of letters. With this relation our young traveller fixed his abode for some time; and, regardless of his original destination, became a cadet in a Prussian regiment of foot. He soon obtained an ensign's commission, and in the space of a few years was advanced to the rank of captain. He quitted the Prussian service on the declaration of war between England and France in 1756, and was honoured with the command of a company in the service of his native country. When peace was concluded in 1760, not choosing, we suppose, to lead a life of inactivity on half pay, he went down to Edinburgh, and commenced student of physic. During his residence at that university, he published his *Clavis Anglica Linguæ Botanicæ;* a book of great utility to all students of botany.

Berkenhout. Having continued some years at Edinburgh, Mr Berkenhout went to the university of Leyden, where he was admitted to the degree of M. D. in the year 1765. On this occasion he published a thesis, intitled, *Dissertatio medica inauguralis de Podagra,* which he dedicated to his relation Baron de Bielfeldt. Returning to England, Dr Berkenhout settled at Isleworth in Middlesex, and soon after published his *Pharmacopæia Medici,* the third edition of which was printed in 1782. In 1778 he was sent by government with the commissioners to America. Neither the commissioners nor their secretary were suffered by the congress to proceed further than New York. Dr Berkenhout, however, found means to penetrate as far as Philadelphia, where the congress was then assembled. He appears to have remained in that city for some time without molestation: but at last they began to suspect that he was sent by Lord North for the purpose of tampering with some of their leading members. The Doctor was immediately seized and committed to prison.

How long he remained a state prisoner, or by what means he obtained his liberty, we are not informed; but we find from the public prints, that he rejoined the commissioners at New York, and returned with them to England. For this temporary sacrifice of the emoluments of his profession, and in consideration of his having, in the service of his sovereign, committed himself to the mercy of a congress of enraged republicans, he obtained a pension.

Many years previous to this event, Dr Berkenhout had published his *Outlines of the Natural History of Great Britain and Ireland,* in three volumes 12mo; a work which established his reputation as a naturalist. In the year 1773 he wrote a pamphlet, entitled, *An Essay on the Bite of a Mad Dog, in which the Claim to Infallibility of the Principal Preservative Remedies, against the Hydrophobia is examined.* This pamphlet is inscribed to Sir George Baker, and deserves to be universally read.

In the year following Dr Berkenhout published his *Symptomatology;* a book which is too universally known to require any recommendation.

At the beginning of the year 1788 he published a work, entitled, *First Lines of the Theory and Practice of Philosophical Chemistry,* which he dedicated to Mr Eden, now Lord Auckland, who had been one of the commissioners whom he accompanied to America.

These, we believe, are the Doctor's principal publications in the line of his profession; but he wrote on many other subjects with equal ability. His translation of *Count Tessin's Letters,* which was his first publication, and dedicated to the present king when prince of Wales, evinces his knowledge of the Swedish language, and shews him to have been a good poet. His *Essay on Ways and Means,* proves him to have been better acquainted with the system of taxation than most other men

men who have written on the fubject. His biographical powers appear in his *Biographia Literaria*; and in all his works are fufficient proofs of his claffical learning, and that the Italian, French, German, and Dutch languages, were familiar to him. He poffeffed likewife a very confiderable degree of mathematical fcience, which he acquired in the courfe of his military ftudies; and to thofe more folid attainments he is faid to have added no fmall fkill in the fine arts of painting and mufic. This eminent man, who, for the variety and promptitude of his knowledge, has been compared to the Admirable Crichton, died on the 3d of April 1791.

BERKLEY, a townfhip in Briftol co. Maffachufetts, containing 850 inhabitants; 50 miles fouthward of Bofton.—*Morse.*

Berkley, the name both of a county and town, in Charlefton Diftrict, S. Carolina, lying near Cooper and Afhley rivers. In the cenfus of 1791, it was called St John's Parifh, in Berkley co. and contained 752 free perfons, and 5170 flaves.—*ib.*

Berkley *Co.* in Virginia, lies W. of the Blue Ridge, N. of Frederick co. and feparated from the ftate of Maryland, on the N. and E. by Potowmack river. This fertile county, about 40 miles long and 20 broad, has 16,781 free inhabitants and 2932 flaves. Martinfburg is its chief town.—*ib.*

Berkley's *Sound,* on the N. W. coaft of N. America, lies on the eaftern fide of Quadras Ifles. The land on its eaftern fide is oppofite Cape Flattery, and forms the N. fide of the Straits de Fuca.—*ib.*

BERK's *Co.* in Pennfylvania, has Northampton co. on the N. E.; Northumberland on the N. W.; part of Luzern on the N.; Dauphin and Lancafter counties S. W. and Chefter and Montgomery S. E. It is watered by Schuylkill River and is 53 miles long and near 29 broad, containing 1,030,400 acres. Here iron ore and coal are found in plenty, which fupply feveral iron works. The northern parts are rough and hilly. Berks contains 30,179 inhabitants, of whom 65 only are flaves. It has 29 townfhips, of which Reading is the chief.—*ib.*

BERKSHIRE *Co.* in Maffachufetts, is bounded W. by New York ftate; S. by the ftate of Connecticut; E. by Hampfhire co. and N. by the ftate of Vermont. It thus runs the whole extent of the ftate from N. to S. and contains twenty-fix townfhips; the chief of which are Stockbridge, Lenox, Great Barrington, Williamftown, and Pittsfield; and the number of inhabitants 30,291. White and clouded marble is found in feveral towns, in the rough and hilly parts of this county. In February, 1796, the legiflature paffed an act to eftablifh a college in Williamftown, by the name of Williams College.—*ib.*

Berkshire, a newly fettled townfhip, in Franklin co. Vermont.—*ib.*

BERLIN, a neat and flourifhing town of York co. Pennfylvania, containing about 100 houfes. It is regularly laid out, on the S. W. fide of Conewago Creek, 13 miles wefterly of Yorktown, and 101 W. of Philadelphia. N. lat. 39. 56.—*ib.*

Berlin, a townfhip in Orange co. Vermont, on Dog River a branch of Onion River from the S.; which laft feparates Berlin from Montpelier, on the N. N. W. Berlin contains 134 inhabitants, and is about 94 miles N. eafterly from Bennington.—*ib.*

Berlin, a townfhip in Hartford co. Connecticut, 12 miles S. S. W. of Hartford, 42 N. W. of New-London; and 26 N. N. E. of New-Haven.—*ib.*

Berlin, a townfhip in Worcefter co. Maffachufetts, containing 512 inhabitants; 34 miles W. of Bofton, and 15 N. E. of Worcefter. Hops have been cultivated here lately, and promifed to be a valuable article of hufbandry.—*ib.*

Berlin, in Somerfet co. formerly in that of Bedford, Pennfylvania, lies on a branch of Stony Creek, a fouth water of Conemaugh River on the W. fide of the Alleghany Mountain; 25 miles weftward of Bedford; 23 N. W. of Fort Cumberland, in Virginia, and 200 W. of Philadelphia. Stone Creek, the chief fource of Kifkeminitas river rifes N. N. E. of Berlin. N. lat. 39. 54.—*ib.*

BERMUDA HUNDRED, or *City Point,* as it is fometimes called, is a port of entry and poft town, in Chefterfield co. Virginia, fituated on the point of the peninfula, formed by the confluence of the Appamattox with James River, 36 miles wefterly from Williamfburg, 64 from Point Comfort, in Chefapeak Bay, and 315 S. W. by S. from Philadelphia. City Point, from which it is named, lies on the fouthern bank of James River, 4 miles S. S. W. from this town. The exports from this place, chiefly collected at Richmond, 20 miles above it, amounted in 1794, to the value of 773,549, dollars; and from the 1ft of October, to 1ft December 1795, were as follow: 15 kegs of butter, 578 bbls. fuperfine flour, 101 half do. 789 fine do. 393 lbs. indigo, 10 tons pig iron, 100 lbs. faffafras, 80,320 hhd. ftaves, 66,300 bbl. ftaves, 1,819 hhds. tobacco, and 3 kegs manufactured do.—Total exports 90,859 dollars, 45 cents. There are about 40 houfes here, including fome warehoufes. It trades chiefly with the W. Indies, and the different ftates. City Point, in James River, lies in N. lat. 37. 16. W. long. 77. 31½.—*ib.*

BERNARD's *Bay,* lies on the N. W. fide of the gulf of Mexico. The paffage into it, between feveral iflands, is called Pafco de Cavallo.—*ib.*

BERNARDSTOWN, in Somerfet co. New-Jerfey, contains 2377 inhabitants, including 93 flaves.

Alfo the name of a townfhip in Hampfhire co. Maffachufetts, containing 691 inhabitants; diftant 110 miles weftward from Bofton.—*ib.*

BERNE, a townfhip in Albany co. New-York. By the ftate cenfus of 1796, it appears there are 447 of the inhabitants who are electors.—*ib.*

BERNOULLI (John), a celebrated mathematician, was born at Bafil the 7th of Auguft 1667. His father intended him for trade; but his own inclination was at firft for the belles lettres, which, however, like his brother James, whofe life is given in the Encyclopædia, he left for mathematics. He laboured with his brother to difcover the method ufed by Leibnitz, in his effays on the differential calculus, and gave the firft principles of the integral calculus. Our author, with Meffis Huygens and Leibnitz, is faid to have been the firft who gave the folution of the problem propofed by James Bernoulli, concerning the catenary, or curve formed by a chain fufpended by its two extremities. But for more on this fubject, fee Arch in this Supplement.

John Bernoulli had the degree of doctor of phyfic at Bafil, and two years afterward was named profeffor of mathematics.

mathematics in the univerfity of Groningen. It was here that he difcovered the mercurial phofphorus, or luminous barometer; and where he refolved the problem propofed by his brother concerning ifoperimetricals.

On the death of his brother James, the profeffor at Bafil, our author returned to his native country, againft the preffing invitations of the magiftrates of Utrecht to come to that city, and of the univerfity of Groningen, who wifhed to retain him. The Academic Senate of Bafil foon appointed him to fucceed his brother, without affembling competitors, and contrary to the eftablifhed practice; an appointment which he held during his whole life.

In 1714 was publifhed his treatife on the management of fhips; and in 1730 his memoir on the elliptical figure of the planets gained the prize of the Academy of Sciences. The fame Academy alfo divided the prize for their queftion concerning the inclination of the planetary orbits, between our author and his fon Daniel. See Bernoulli (Daniel), *Encycl.*

John Bernoulli was a member of moft of the academies of Europe, and received as a foreign affociate of that of Paris in 1699. After a long life fpent in conftant ftudy and improvement of all the branches of the mathematics, he died full of honours, the 1ft of January 1748, in the 81ft year of his age. Of five fons which he had, three purfued the fame fciences with himfelf. One of thefe died before him; the two others, Nicolas and Daniel, he lived to fee become eminent, and much refpected in the fame fciences.

The writings of this great man were difperfed through the periodical memoirs of feveral academies, as well as in many feparate treatifes. And the whole of them were carefully collected and publifhed at Laufanne and Geneva, 1742, in 4 vols. 4to. He was of undoubted eminence; but even in fcience he was a hafty man, and certainly envious of the fame of Newton.

BERTIE, a maritime co. in N. Carolina, in Edenton diftrict, with the Roanoke its S. boundary, and Albemarle Sound on the E. In it is fituated the ancient Indian tower of Tufcarora. It contains 12,606 fouls, of which number 5141 are flaves.—*Morse.*

BERWICK, or *Abbotftown*, a neat town in York co. Pennfylvania, at the head of Conewago Creek, 13 miles weftward of York, 26 S. S. W. of Harrifburg, and 103 W. by S. of Philadelphia. The town is regularly laid out, and contains about 100 houfes, a German Lutheran, and a Calvinift church. N. lat. 39. 54.—*ib.*

Berwick, or *New-Berwick*, a fmall town of Northumberland co. Pennfylvania, on the N. weftern fide of the E. branch of Sufquehannah River oppofite Nefcopeck Falls, and Nefcopeck Creek, 32½ miles N. E. from Northumberland and Sunbury, at the junction of the E. with the W. branch of Sufquehannah, and 160 N. W. of Philadelphia. N. lat. 41. 3.—*ib.*

Berwick, a townfhip in York co. Diftrict of Maine, containing 3894 inhabitants. It has an incorporated academy, and lies on the E. fide of Salmon Fall River, 7 miles N. W. of York, and 86 E. of N. from Bofton.—*ib.*

BETELGEUSE, a fixed ftar of the firft magnitude, in the right fhoulder of Orion.

BETHABARA, the firft fettlement of the Moravians in the lands of Wachovia, in N. Carolina, begun in 1753; 6 miles N. of Salem, and 183 W. of Halifax, in N. lat. 36. 9. It is fituated on the W. fide of Graffy Creek, which unites with the Gargales, and feveral others; and falls into the Yadkin. It contains a church of the United Brethren, and about 50 dwelling houfes.—*Morse.*

BETHANY, or *Bethania*, a Moravian fettlement and poft town, in the lands of Wachovia, in N. Carolina, begun in 1760; 9 miles N. W. of Salem, 4 N. W. of Bethabara, and 568 S. W. by S. of Philadelphia. It contains about 60 houfes, and a church, built on a regular plan.—*ib.*

BETHEL, a fmall Moravian fettlement on Swetara River in Pennfylvania, 12 miles from Mount Joy.—— A townfhip in Dauphin county.—*ib.*

Bethel, a townfhip in Windfor co. Vermont, containing 473 inhabitants; N. N. W. of, and bounded by Stockbridge, and about 67 miles N. N. eafterly of Bennington. It gives rife to a fmall branch of White River.—*ib.*

Bethel, a townfhip in Delaware co. Pennfylvania. —*ib.*

Bethel (Mount) a townfhip in Northampton county, Pennfylvania.

BETHLEHEM, a town in Albany co. New-York, very fruitful in paftures, and has large quantities of excellent butter. By the ftate cenfus of 1796, 388 of the inhabitants are electors.—*ib.*

Bethlehem, a townfhip in Berkfhire co. Maffachufetts, having 261 inhabitants. It lies about 10 miles S. of E. from Stockbridge, 10 from Lenox, and 130 from Bofton. It borders on Tyringham and Loudon.—*ib.*

Bethlehem, a townfhip in Hunterdon co. New-Jerfey, fituated at the head of the S. branch of Rariton River. It contains 1335 inhabitants, including 31 flaves. Turf for firing is found here.—*ib.*

Bethlehem, a townfhip in Litchfield co. Connecticut, joins Litchfield on the N. and Woodbury on the S.—*ib.*

Bethlehem, a poft town in Northampton co. Pennfylvania, is a celebrated fettlement of the Moravians, or *United Brethren*, of the Proteftant Epifcopal church, as they term themfelves. It is fituated on Lehigh River a weftern branch of the Delaware, 53 miles northerly from Philadelphia, and 18 foutherly from the *Wind Gap*. The town ftands partly on the lower banks of the Manakes, a fine creek, which affords trout and other fifh. The fituation is healthful and pleafant, and in fummer is frequented by gentry from different parts. In 1787, there were 60 dwelling houfes of ftone, well built, and 600 inhabitants. Befides the meeting-houfe, are 3 other public buildings, large and fpacious; one for the fingle brethren, one for the fingle fifters, and the other for the widows. The literary eftablifhments, as well as the religious regulations, here, deferve notice.—In a houfe adjoining to the church, is a fchool for females; and fince 1787, a boarding fchool for young ladies, who are fent here from different parts, and are inftructed in reading and writing (in the Englifh and German tongues) grammar, arithmetic, geography, needle work, mufic, &c. The minifter of the place has the direction of this as well as of the boys fchool, which is kept in a feparate houfe, where they are initiated in the fundamental branches of literature. Thefe fchools, efpecially that for

for the young ladies, are deservedly in very high repute; and scholars, more than can be accommodated, are offered from all parts of the United States.

There is at the lower part of the town a machine, of simple construction, which raises the water, from a spring, into a reservoir, to the height of 100 feet; whence it is conducted by pipes into the several streets of the town.

There is a genteel tavern at the N. end of the town, the profit arising from which, belongs to the society. There is also a store, with a general assortment of goods, an apothecary's shop, a large tan-yard, a currier's, and a dyer's shop, a grist-mill, a fulling-mill, an oil-mill, and a saw-mill, and on the banks of the Lehigh, a brewery. N. lat. 40. 37. W. long. 75. 14. —*Morse.*

BEVERLY, a township and post town in Essex co. Massachusetts, containing 3290 inhabitants, is separated from Salem by a handsome bridge, and is about 20 miles E. of N. of Boston, and 22 S. W. of Newburyport. It has two parishes. In the parish next the harbor, are a number of handsome houses, exhibiting the cheering rewards of enterprise and industry, and the inhabitants are devoted to the fishery and other branches of navigation. In the other part of the town, which is chiefly agricultural, is a cotton manufactory. The bridge, mentioned before, is 1500 feet in length, erected in 1788, and connects this town with Salem. It has a draw for vessels.—*ib.*

BEVERLY'S *Manor*, or *Irish Tract*, in Virginia, is a tract of land, in N. lat. 38. 10. at the head of Massanuten's River, a western branch of the Shenandoah, which rises here by three branches, viz. Middle River, Lewis and Christian Creeks. It lies between the Blue, and the North Ridge. The road from Yadkin River, through Virginia to Philadelphia, passes through here. —*ib.*

BEZOUT (Stephen), a celebrated French mathematician, member of the Academies of Sciences and the Marine, and examiner of the guards of the marine and of the eleves of artillery, was born at Nemours the 31st of March 1730. In the course of his studies he met with some books of geometry, which gave him a taste for that science; and the Eloges of Fontenelle, shewed him the honours attendant on talents and the love of the sciences. His father in vain opposed the strong attachment of young Bezout to the mathematical sciences. April 8, 1758, he was named adjoint-mechanician in the French Academy of Sciences; having before that sent them two ingenious memoirs on the integral calculus, and given other proofs of his proficiency in mathematics. In 1763, he was named to the new office of examiner to the marine, and appointed to compose a system of mathematics for their use; and in 1768, on the death of M. Camus, he succeeded as examiner of the artillery eleves.

Bezout fixed his attention more particularly to the resolution of algebraic equations; and he first found out the solution of a particular class of equations of all degrees. This method, different from all former ones, was general for the cubic and biquadratic equations, and just became particular only at those of the 5th degree. Upon this work our author laboured from 1762 till 1779, when he published it. He composed two courses of mathematics; the one for the marine, the other for the artillery. The foundation of these two works was the same; the applications only being different, according to the two different objects: these courses have every where been held in great estimation. In his office of examiner he discharged the duties with great attention, care, and tenderness. A trait of his justice and zeal is remarkable in the following instance: During an examination which he held at Toulon, he was told that two of the pupils could not be present, being confined by the small-pox: he himself had never had that disease, and he was greatly afraid of it; but as he knew that if he did not see these two young men, it would much impede their improvement, he ventured to their bed sides to examine them, and was happy to find them so deserving of the hazard into which he put himself for their benefit.

Mr Bezout lived in this employment for several years, beloved of his family and friends, and respected by all, enjoying the fruits and the credit of his labours. But the trouble and fatigues of his offices, with some personal chagrines, had reduced his strength and constitution; he was attacked by a malignant fever, of which he died Sept. 27, 1783, in the 54th year of his age, regretted by his family, his friends, the young students, and by all his acquaintance in general.

The books published by him were: 1. Course of Mathematics for the use of the Marine, with a Treatise on Navigation, 6 vols in 8vo, Paris, 1764. 2. Course of Mathematics for the Corps of Artillery, 4 vols in 8vo, 1770. 3. General Theory of Algebraic Equations, 1779.

His papers printed in the volumes of the Memoirs of the Academy of Sciences are: 1. On curves, whose rectification depends on a given quantity, in the volume for 1758. 2. On several classes of equations that admit of an algebraic solution, 1762. 3. First volume of a course of mathematics, 1764. 4. On certain equations, &c. 1764. 5. General resolution of all equations, 1765. 6. Second volume of a course of mathematics, 1765. 7. Third volume of the same, 1766. 8. Fourth volume of the same, 1767. 9. Integration of differentials, &c. vol. 3. Sav. Etr. 10. Experiments on cold, 1777.

BIG BONE *Creek*, in Woodford co. Kentucky, falls into the Ohio from the E. in about N. lat. 39. 17. W. long. 85. 54. It is very small in size, and has three branches; the N. westernmost interlocks with Bank Lick Creek, which falls into Licking River. It is only noticeable for the large bones, and salt licks near it.—*Morse.*

BIG BONE LICKS, THE, lie on each side of the above-mentioned creek, a little below the junction of the two eastern branches, about 8 miles from the mouth of the creek. These, as also the other salt springs, in the western country, are called *Licks*, because the earth about them is furrowed up in a most curious manner, by the buffaloes and deer which lick the earth, on account of the saline particles with which it is impregnated. A stream of brackish water runs through these licks, the soil of which is a soft clay.—The large bones found here, and in several other places near salt licks, and in low soft grounds, thought to belong to the mammoth, still puzzle the most learned naturalists to determine to what animal they have belonged. A thigh bone found here by General Parsons, measured *forty-nine* inches in length. A tooth of this animal is deposited in Yale College. Mr Jefferson, who ſeems to have examined the ſkeleton of one of theſe animals with curious attention, ſays, that "The bones beſpeak an animal of *five or ſix times* the cubic volume of an elephant," as M. Buffon has admitted. Of this animal the natives have no tradition, but what is ſo fabulous, that no conjecture can be aided by it, except that the animal was carnivorous; and this is the general opinion, and was admitted by the late Dr Hunter, of London, from an examination of the tuſks, &c.—*Morſe.*

BIG SANDY *River*, or *Tottervy*, has its ſource near that of Cumberland River; and, ſeparating Virginia from Kentucky, empties into the Ohio, oppoſite the French Purchaſe of Galiopolis, in about N. lat. 38. 30. Vancouver's and Harmar's forts ſtand on this river. On its banks are ſeveral ſalt licks and ſprings. *Little Sandy*, is a ſhort, ſmall river, which falls into the Ohio, about 20 miles W. of Big Sandy River in Maſon co. Kentucky.—*ib.*

BILLERICA, a townſhip in Middleſex co. Maſſachuſetts, incorporated in 1655. It has 1200 inhabitants; nor has there been much variation in the number for half a century. It lies 20 miles northward of Boſton, and is watered by Concord and Shawſheen rivers, which run N. eaſterly into Merrimack River. —*ib.*

BILLINGSPORT, on Delaware River, lies 12 miles below Philadelphia, was fortified in the late war, for the defence of the channel. Oppoſite this fort, ſeveral large frames of timber, headed with iron ſpikes, called *chevaux de friſes*, were ſunk to prevent the Britiſh ſhips from paſſing. Since the peace, a curious machine has been invented in Philadelphia, to raiſe them.—*ib.*

BINOMIAL, a quantity conſiſting of two terms or members, connected by either of the ſigns + and —. See ALGEBRA, def. 9. *Encycl.*

Impoſſible or *Imaginary* BINOMIAL, is a binomial which has one of its terms an impoſſible or an imaginary quantity; as $a + \sqrt{-b}$.

BINOMIAL *Curve*, is a curve whoſe ordinate is expreſſed by a binomial quantity, as the curve whoſe ordinate is $x^a \times \overline{b + d x^c}|^e$. Stirling, Method. Diff. p. 58.

BINOMIAL *Line*, or *Surd*, is that in which at leaſt one of the parts is a ſurd. Euclid, in the tenth book of his Elements, enumerates ſix kinds of binomial lines or ſurds, viz.

Firſt binomial $3 + \sqrt{5}$,
2d binomial $\sqrt{18} + 4$,
3d binomial $\sqrt{24} + \sqrt{18}$,
4th binomial $4 + \sqrt{3}$,
5th binomial $\sqrt{6} + 2$,
6th binomial $\sqrt{6} + \sqrt{2}$.

BINOMIAL *Theorem*. See ALGEBRA, Chap. VII. Sect. iii. (*Encycl.* Vol. I.); and *Infinite* SERIES, (Vol. XVII.) The reader who wiſhes for a fuller account of this famous theorem, may find it in Dr Hutton's Mathematical Tracts, Vol. I.

BIRD-CATCHING, is an art which, as it is practiſed by means of bird-lime, nets, decoys, &c. has been ſufficiently explained in the Encyclopædia. But there is another method of catching birds alive, by means of a *fuſee* or *muſket*, which was invented by M. Vaillant during his travels in Africa, and is ſufficiently ingenious to deſerve a place here. It is as follows:

Put a ſmaller or larger quantity of powder into your fuſee according as circumſtances may require. Immediately above the powder place the end of a candle of ſufficient thickneſs, ramming it well down; and then fill the barrel with water up to the mouth. When at a proper diſtance you fire a muſket thus loaded at a bird, you will only *ſtun* it by watering and moiſtening its feathers; and if you be alert, you may eaſily lay hold of it before it have time to ſpoil its plumage by fluttering. Our author admits, that in his firſt attempts he often put too much powder, or too thick a piece of candle into his fuſee, or fired at too ſhort a diſtance; and when any one of theſe miſtakes was committed, he generally found the candle entire in the animal's belly; but after a ſhort apprenticeſhip he acquired ſufficient ſkill to adjuſt matters ſo as that the water impelled by the powder went directly to the mark, whilſt the tallow being lighter than the water fell ſhort of it. If this method be indeed practicable (for not being ſportſmen we have not made trial of it), it may on many occaſions aid the reſearches of the ornithologiſt.

BIRDS *Neſts*, in cookery. See *Encycl.* and CAP and BUTTON in this *Suppl.*

BLACKLOCK (Dr Thomas) deſerves, on ſo many accounts, to have the principal incidents of his life recorded in this work, that to omit ſuch an article from our liſt of biographical ſketches would be unpardonable negligence. We cannot, however, propoſe to write of him any thing which has not been written before, by an author who has repeatedly appeared before the public, and on each appearance has gained poſſeſſion of the public heart. We ſhall therefore content ourſelves with inſerting in this place a ſhort abridgment of the elegant account of the life and writings of Dr Blacklock, which was prefixed to that edition of his works which was publiſhed in 1793; and if we thus leſſen our own labour, we are conſcious that we ſhall at the ſame time increaſe the pleaſure of our readers.

Thomas Blacklock was in 1721 born at Anan, in the county of Dumfries in Scotland, but his parents were natives of the bordering county of Cumberland; ſo that, though a native of Scotland, his deſcent was Engliſh. His father was a bricklayer, and his mother the daughter of a conſiderable dealer in cattle. Both were reſpectable in their characters, and poſſeſſed, tho' moving in an humble ſphere, a conſiderable degree of knowledge and urbanity. Their ſon was not quite ſix months old when he loſt his eye-ſight in the ſmall-pox, which rendered him as complete a ſtranger to the viſible world as if he had been blind from the hour of his birth. It rendered him likewiſe incapable of learning any of the mechanical arts; and therefore his father kept him at home, and with the aſſiſtance of ſome friends foſtered that inclination which, at a very early period, he ſhewed for books. This was done by reading to him firſt the ſimple ſort of publications which are commonly put into the hands of children, and then ſeveral of our beſt authors, ſuch as Milton, Spencer, Prior, Pope, and Addiſon. His companions, whom his early gentleneſs and kindneſs of diſpoſition, as well as their compaſſion for his misfortune, ſtrongly attached to him, were very aſſiduous in their good offices, in reading to inſtruct and amuſe him. By their aſſiſtance he acquired ſome knowledge of the Latin tongue, but he never was at a grammar ſchool till at a more advanced period of life.

life. Poetry was even then his favourite reading; and he found an enthusiastic delight in the works of the best English poets, and in those of his countryman Allan Ramsay. Even at an age so early as twelve he began to write poems, one of which is preserved in the collection that was published after his death, and is not perhaps inferior to any of the premature compositions of boys assisted by the best education, which are only recalled into notice by the future fame of their authors.

He had attained the age of nineteen when his father was killed by the accidental fall of a malt-kiln belonging to his son-in-law. This loss, heavy to any one at that early age, would have been, however, to a young man possessing the ordinary means of support, and the ordinary advantages of education, comparatively light; but to him—thus suddenly deprived of that support on which his youth had leaned—destitute almost of every resource which industry affords to those who have the blessings of sight—with a body feeble and delicate from nature, and a mind congenially susceptible—it was not surprising that this blow was doubly severe, and threw on his spirits that despondent gloom to which he then gave way in the following pathetic lines, and which sometimes overclouded them in the subsequent period of his life.

> " Dejecting prospect! soon the hapless hour
> " May come; perhaps this moment it impends,
> " Which drives me forth to penury and cold,
> " Naked, and beat by all the storms of heav'n,
> " Friendless and guideless to explore my way;
> " Till, on cold earth this poor unshelter'd head
> " Reclining, vainly from the ruthless blast
> " Respite I beg, and in the shock expire."

He lived with his mother for about a year after his father's death, and began to be distinguished as a young man of uncommon parts and genius. These were at that time unassisted by learning; the circumstances of his family affording him no better education than the smattering of Latin which his companions had taught him, and the perusal and recollection of the few English authors which they, or his father in the intervals of his professional labours, had read to him. Poetry, however, though it attains its highest perfection in a cultivated soil, grows perhaps as luxuriantly in a wild one. To poetry, as we have before mentioned, he was devoted from his earliest days; and about this time several of his poetical productions began to be handed about, which considerably enlarged the circle of his friends and acquaintance. Some of his compositions being shewn to Dr Stevenson, an eminent physician of Edinburgh, who was accidentally at Dumfries on a professional visit, that gentleman formed the benevolent design of carrying him to the Scotch metropolis, and giving to his natural endowments the assistance of a classical education. He came to Edinburgh in the year 1741, and was enrolled a student of divinity in the university there, though at that time without any particular view of entering into the church. In that university he continued his studies under the patronage of Dr Stevenson till the year 1745, when he retired to Dumfries, and resided in the house of Mr M'Murdo, who had married his sister, during the whole time of the civil war which then raged in the country, and particularly disturbed the tranquillity of the metropolis. When peace was restored to the nation, he returned to the university, and pursued his studies for six years longer. During this last residence in Edinburgh, he obtained, among other literary acquaintance, that of the celebrated David Hume, who attached himself warmly to Mr Blacklock's interests, and was afterwards particularly useful to him in the publication of the 4to edition of his Poems, which came out by subscription in London in the year 1756. Previously to this, two editions in 8vo had been published at Edinburgh, the first in 1746, and the second in 1754.

In the course of his education at Edinburgh, he acquired a proficiency in the learned languages, and became more a master of the French tongue than was then common in that city. For this last acquisition he was chiefly indebted to the social intercourse to which he had the good fortune to be admitted in the house of Provost Alexander, who had married a native of France. At the university he attained a knowledge of the various branches of philosophy and theology, to which his course of study naturally led, and acquired at the same time a considerable fund of learning and information in those various departments of science and belles lettres, from which his want of sight did not absolutely preclude him.

In 1757, he began a course of study, with a view to give lectures in oratory to young gentlemen intended for the bar or the pulpit. On this occasion he wrote to Mr Hume, informed him of his plan, and requested his assistance in the prosecution of it. But Mr Hume doubting the probability of its success, he abandoned the project; and then, for the first time, adopted the decided intention of going into the church of Scotland. After applying closely for a considerable time to the study of theology, he passed the usual trials in the presbytery of Dumfries, and was by that presbytery licensed a preacher of the gospel in the year 1759. As a preacher he obtained high reputation, and was fond of composing sermons, of which he has left some volumes in manuscript, as also a Treatise on Morals.

The tenor of his occupations, as well as the bent of his mind and dispositions, during this period of his life, will appear in the following plain and unstudied account, contained in a letter from a gentleman, who was then his most intimate and constant companion, the Rev. Mr Jameson, formerly minister of the Episcopal chapel at Dumfries, afterwards of the English congregation at Dantzic, and who lately resided, and perhaps yet resides, at Newcastle upon Tyne.

" His manner of life (says that gentleman) was so uniform, that the history of it during one day, or one week, is the history of it during the seven years that our personal intercourse lasted. Reading, music, walking, conversing, and disputing on various topics, in theology, ethics, &c. employed almost every hour of our time. It was pleasant to hear him engaged in a dispute, for no man could keep his temper better than he always did on such occasions. I have known him frequently very warmly engaged for hours together, but never could observe one angry word to fall from him. Whatever his antagonist might say, *he* always kept his temper. '*Semper paratus et refellere sine pertinacia, et refelli sine iracundia.*' He was, however, extremely sensible to what he thought ill-usage, and equally so whether it regarded himself or his friends. But his resentment

ment was always confined to a few fatirical verfes, which were generally burnt foon after.

"I have frequently admired with what readinefs and rapidity he could fometimes make verfes. I have known him dictate from thirty to forty verfes, and by no means bad ones, as faft as I could write them; but the moment he was at a lofs for a rhime or a verfe to his liking, he ftopt altogether, and could very feldom be induced to finifh what he had begun with fo much ardour."

This account fufficiently marks that eager fenfibility, chaftened at the fame time with uncommon gentlenefs of temper, which characterifed Dr Blacklock, and which indeed it was impoffible to be at all in his company without perceiving. In the fcience of mind, this is that divifion of it which perhaps one would peculiarly appropriate to poetry, at leaft to all thofe lighter fpecies which rather depend on quicknefs of feeling, and the ready conception of pleafing images, than on the happy arrangement of parts, or the fkilful conftruction of a whole, which are effential to the higher departments of the poetical art. The firft kind of talent is like thofe warm and light foils which produce their annual crops in fuch abundance; the laft, like that deeper and firmer mould on which the roots of eternal forefts are fixed. Of the firft we have feen many happy inftances in that fex which is fuppofed lefs capable of ftudy or thought; from the laft is drawn that mafculine fublimity of genius which could build an Iliad or a Paradife Loft.

Dr Blacklock could never dictate till he ftood up; and as his blindnefs made walking about without affiftance inconvenient or dangerous to him, he fell infenfibly into a vibratory fort of motion of his body, which increafed as he warmed with his fubject, and was pleafed with the conceptions of his mind. This motion at laft became habitual to him; and though he could fometimes reftrain it when on ceremony, or on any public appearance, fuch as preaching, he felt a certain uneafinefs from the effort, and always returned to it when he could without impropriety. This appearance he defcribes in a fhort poem, in which he gives a ludicrous picture of himfelf; a picture indeed, of which, though the outlines are true, the general effect is greatly overcharged. Though his features were hurt by the difeafe which deprived him of fight, there was a certain placid expreffion in his countenance, which marked the benevolence of his heart, and was calculated to procure to him individual attachments and general regard.

In 1762 he married Mifs Sarah Johnfon, daughter of Mr Jofeph Johnfon furgeon in Dumfries; a connection which formed the great folace and bleffing of his future life, and gave him, with all the tendernefs of a wife, all the zealous care of a guardian and a friend. This event took place a few days before his being ordained minifter of the town and parifh of Kircudbright, in confequence of a prefentation from the crown, obtained for him by the earl of Selkirk, a benevolent nobleman, whom Mr Blacklock's fituation and genius had interefted in his behalf. But the inhabitants of the parifh, whether from that violent averfion to patronage, which was then fo univerfal in the fouthern parts of Scotland, from fome political difputes which at that time fubfifted between them and his noble patron, or from thofe prejudices which fome of them might naturally enough entertain againft a paftor deprived of fight, or perhaps from all thefe caufes united, were fo extremely difinclined to receive him as their minifter, that after a legal difpute of nearly two years, it was thought expedient by his friends, as it had always been wifhed by himfelf, to compromife the matter, by refigning his right to the living, and accepting a moderate annuity in its ftead. With this flender provifion he removed in 1764 to Edinburgh; and to make up by his induftry a more comfortable and decent fubfiftence, he adopted the plan of receiving a certain number of young gentlemen as boarders into his houfe, whofe ftudies in languages and philofophy he might, if neceffary, affift. In this fituation he continued till the year 1787, when he found his time of life and ftate of health required a degree of quiet and repofe which induced him to difcontinue the receiving of boarders. In 1767 the degree of doctor in divinity was conferred on him by the univerfity and Marifchal college of Aberdeen.

In the occupation which he thus exercifed for fo many years of his life, no teacher was perhaps ever more agreeable to his pupils, nor mafter of a family to its inmates, than Dr Blacklock. The gentlenefs of his manners, the benignity of his difpofition, and that warm intereft in the happinefs of others which led him fo conftantly to promote it, were qualities that could not fail to procure him the love and regard of the young people committed to his charge; while the fociety, which efteem and refpect for his character and his genius often affembled at his houfe, afforded them an advantage rarely to be found in eftablifhments of a fimilar kind.

In this mixed fociety he appeared to forget the privation of fight, and the melancholy which it might at other times produce in his mind. He entered, with the cheerful playfulnefs of a young man, into all the fprightly narrative, the fportful fancy, and the humorous jeft that rofe around him. Next to converfation, mufic was perhaps the fource of his greateft delight; for he not only relifhed it highly, but was himfelf a tolerable performer on feveral inftruments, particularly the flute. He generally carried in his pocket a fmall *flageolet*, on which he played his favourite tunes; and was not difpleafed when afked in company to play or to fing them; a natural feeling for a blind man, who thus adds a fcene to the drama of his fociety.

Of the happinefs of others, however, we are incompetent judges. Companionfhip and fympathy bring forth thofe gay colours of mirth and cheerfulnefs which they put on for a while, to cover perhaps that fadnefs which we have no opportunity of witneffing. Of a blind man's condition we are particularly liable to form a miftaken eftimate; we give him credit for all thofe gleams of delight which fociety affords him, without placing to their full account thofe dreary moments of darkfome folitude to which the fufpenfion of that fociety condemns him. Dr Blacklock had from nature a conftitution delicate and nervous, and his mind, as is almoft always the cafe, was in a great degree fubject to the indifpofition of his body. He frequently complained of a lownefs and depreffion of fpirits, which neither the attentions of his friends, nor the unceafing care of a moft affectionate wife, were able entirely to remove. The imagination we are fo apt to envy and admire ferves but to irritate this diforder of the mind; and that fancy in whofe creation we fo much delight, can draw, from fources

Blacklock.

sources unknown to common men, subjects of disgust, disquietude, and affliction. Some of his later poems express a chagrin, though not of an ungentle sort, at the supposed failure of his imaginative powers, or at the fastidiousness of modern times, which he despaired to please.

" Such were his efforts, such his cold reward,
" Whom once thy partial tongue pronounc'd a bard;
" Excursive, on the gentle gales of spring,
" He rov'd, whilst favour imp'd his timid wing;
" Exhausted genius now no more inspires,
" But mourns abortive hopes, and faded fires;
" The short-liv'd wreath, which once his temples grac'd,
" Fades at the sickly breath of squeamish taste;
" Whilst darker days his fainting flames immure
" In cheerless gloom and winter premature."

These lines are, however, no proof of " exhausted genius," or " faded fires." " Abortive hopes," indeed, must be the lot of all who, like Dr Blacklock, reach the period of old age. In early youth the heart of every one is a poet; it creates a scene of imagined happiness and delusive hopes; it clothes the world in the bright colours of its own fancy; it refines what is coarse, it exalts what is mean; it sees nothing but disinterestedness in friendship, it promises eternal fidelity in love. Even on the distresses of its situation it can throw a certain romantic shade of melancholy that leaves a man sad, but does not make him unhappy. But at a more advanced age, " the fairy visions fade," and he suffers most deeply who has indulged them the most.

About the time that these verses were written, Dr Blacklock was, for the first time, afflicted with what to him must have been peculiarly distressful. He became occasionally subject to deafness, which, though he seldom felt it in any great degree, was sufficient, in his situation, to whom the sense of hearing was almost the only channel of communication with the external world, to cause very lively uneasiness. Amidst these indispositions of body, however, and disquietudes of mind, the gentleness of his temper never forsook him, and he felt all that resignation and confidence in the Supreme Being which his earliest and his latest life equally acknowledged. In summer 1791 he was seized with a feverish disorder, which at first seemed of a slight, and never rose to a very violent kind; but a frame so little robust as his was not able to resist it, and after about a week's illness it carried him off on the 7th day of July 1791. His wife survives him, to feel, amidst the heavy affliction of his loss, that melancholy consolation which is derived from the remembrance of his virtues.

The writings of Dr Blacklock consisted principally of poems, which were published in 4to in the year 1793; and to that edition was added, *An Essay on the Education of the Blind, translated from the French of M. Hauy*. But besides his avowed works, we have reason to believe that he was the author of many articles in the second edition of the *Encyclopædia*, though we cannot say with certainty what those articles were. If our memory does not deceive us, we have been informed that the preface to that edition was furnished by him; and we have elsewhere attributed to him, on the best authority, the article Blind, and the *Notes* to the article Music: but he undoubtedly contributed much more to the work, and was one of the principal guides of the proprietors.

Black ‖ Blanco.

BLACK *River*. There are two small rivers of this name in Vermont, one falls into Connecticut River at Springfield, the other runs N. into Lake Memphremagog.—*Morse*.

Black *River*, in N. York, interlocks with Canada Creek, and runs N. W. into Iroquois River, boatable 60 miles. Also, a long river which rises in Virginia, and passes south easterly into Nottaway River in N. Carolina.—*ib*.

Black *River*, a British settlement at the mouth of Tinto River, 20 leagues to the E. of Cape Honduras, the only harbor on the coast of Terra Firma, from the island of Rattan to Cape Gracias a Dios, and was for more than 60 years the refuge of the logwood cutters, when the Spaniards drove them from the forests of East Yucatan, which occasioned adventurers of different kinds to settle here, where the coast is sandy, low and swampy; higher up near the rivers and lagoons, which are full of fish, the soil is more fertile, and produces plantanes, cocoa-trees, maize, yams, potatoes, and variety of vegetables; and the passion for drinking spirits, made them plant sugar canes. The forests are full of deer, Mexican, swine and game. The shores abound with turtle, and the woods with mahogany, zebra-wood, sarsaparilla, &c. and indeed the whole settlement flourishes spontaneously without cultivation. —*ib*.

Black *River*, in the island of Jamaica, passes through a level country, is the deepest and largest in the island, and will admit flat bottomed boats and canoes for about 30 miles.—*ib*.

BLADEN, a county of N. Carolina, in Wilmington district. It has 5084 inhabitants, including 1676 slaves.—*ib*.

BLADENSBURG, a post town in Prince George co. Maryland, on the eastern bank of the eastern branch of Potowmack River at the confluence of the N. W. and N. E. branches; 9 miles from its mouth at the Federal City; 38 S. W. from Baltimore, and 12 N. E. from Alexandria, in Virginia. It contains about 150 houses, and a ware-house for the inspection of tobacco.—*ib*.

BLANCO *Capes*. There are many capes of this name, as follow. 1. The N. western point of the bay of Salinas, in the 10th degree of N. latitude; and on the coast of Terra Firma; and, in other maps, is called the N. western point of the gulf of Nicoya.—2. On the coast of California, at the broadest part of the peninsula, in the 32d degree of N. latitude.—3. On the N. W. coast of America, in New-Albion, southward of the mouth of what has been called the *River of the West*, in the 44th degree of N. latitude.—4. A promontory of Peru, in S. America, on the coast of the S. Sea, 120 miles S. W. of Guayaquil, S. lat. 3. 45. W. long. 83.—5. A cape in the southern ocean, on the E. side of Patagonia, S. eastward of Julian Bay, in the 47th degree of S. latitude, 8 leagues W. of Pepys's Island.—*ib*.

Blanco, or *Blanca*, an island 35 leagues from Terra Firma, and N. of Margarita Island in the province of New-Andalusia. It is flat, low, and uninhabited; having savannahs of long grass; is dry and healthy; has plenty of guanas, and some trees of lignumvitæ. N. lat. 11. 50. W. long. 64. 50.—*ib*.

Blanco || Bleaching.

BLANCO, an island on the S. eastern part of the peninsula of Yucatan, in New-Spain. N. lat. 21. W. long. 88. 5.—*Morse.*

BLANDFORD, a township in Hampshire co. Massachusetts, W. of Connecticut River; about 25 miles S. W. of Northampton, and 116 W. of Boston. It has 235 houses, and 1416 inhabitants.—*ib.*

BLANDFORD, a town in Prince George co. Virginia, about 4 miles N. E. from Petersburgh, and is within its jurisdiction. It contains 200 houses and 1200 inhabitants, and is pleasantly situated on a plain, on the eastern branch of Appamattox River. Here are many large stores, and 3 tobacco ware-houses which receive annually 6 or 7000 hhds. It is a thriving place; and the marshes in its vicinity being now drained, the air of this town, and that of Petersburgh, is much meliorated.—*ib.*

BLEACHING. Since the article *Bleaching* in the Encyclopædia was written, very great improvements have been introduced into the art. Of these improvements we shall proceed to give an account.

1 Discovery of the oxy-muriatic acid.

Mr Scheele of Sweden discovered the oxy-muriatic acid, or dephlogisticated muriatic acid, as he called it, about the year 1774, and soon after observed its effects on vegetable colours. His method of procuring it was as follows: In a sand bath is to be placed a glass retort, in which muriatic acid has been poured upon manganese; to this small receivers are to be adapted capable of containing about twelve ounces each, into which is to be poured about two drachms of water, without any other lute than a slip of blotting-paper about the neck of the retort. In about a quarter of an hour a yellow air is perceived in the receiver, which is to be taken off. If the paper has been properly applied, the air rushes out forcibly; the receiver must be quickly stopped, and another applied. Thus many receivers may be filled with the dephlogisticated muriatic acid; but it is necessary to place the retort in such a manner that the drops which rise into its neck may be able to fall back. The water serves to retain the vapours of the acid. "I use (says he) many receivers, that I may not be obliged to repeat a similar distillation for every experiment. It is not proper to employ large ones, because every time they are opened, a great part of the acid is dissipated in the air. What I submitted to examination with this dephlogisticated muriatic acid was placed in the neck of the receiver, which I had stopped. The cork was turned yellow, as by aquafortis. Paper tinged with turnsol became almost white; all red, blue, and yellow flowers, as also green plants, turned yellow in a short time, and the water in the receiver was changed into a pure but weak muriatic acid. Neither alkalis nor acids were able to restore the colours of the flowers, or of the plants."

M. Berthollet, in 1785, proved that this acid was composed of muriatic acid combined with oxygen; and that when it had deprived vegetable matters of their colour, it was reduced to the state of common muriatic acid; that is, it had lost the oxygen with which it was united. This oxygen had combined with the colouring particles of the vegetable matter, and had rendered them colourless. After making these observations, it occurred to him that the oxy-muriatic acid might produce the same effect upon those particles which give colour to thread and cloth, and which it is the object of bleaching to destroy. "At first (says he) I made use of water highly impregnated with this acid; and I renewed it when it was exhausted, until the thread or cloth appeared white; but I soon perceived that they were considerably weakened, and that they were entirely losing their solidity. I then weakened the liquor a little, and I succeeded in bleaching cloth without damaging it. But it speedily became yellow by keeping, especially if it was warmed, or passed through an alkaline ley. I reflected upon the circumstances of common bleaching, and I endeavoured to imitate its process, because I thought the oxygenated muriatic acid might act in the same manner as the exposition of the cloth in the meadows, which alone does not suffice, but which appears only to dispose the colouring parts of the cloth to be dissolved by the alkali of the ley. I examined dew, not only that which falls from the atmosphere, but also that which comes from the nocturnal transpiration of plants; and I observed that both of them were impregnated with oxygen, sufficiently to destroy the colour of paper slightly tinged with turnsol.

2 Its application to bleaching.

Ann. de Chym. II. 158.

"I therefore employed leys, and the action of oxygenated muriatic acid, alternately, and I then obtained a permanent white; and as, at the finishing of the common bleaching, the cloth is passed through sour milk, or through sulphuric acid diluted with a very large quantity of water, I also tried passing the cloth through a very dilute solution of sulphuric acid, and I observed that the white was thereby rendered more clear. As soon as I made use of the leys intermediately, I found that it was not necessary to employ a concentrated liquor, or to let the cloth, at every immersion, remain long therein: by this I avoided two inconveniences, which would have rendered this process impossible to be practised in the large way. The first is the suffocating odour of the liquor, which it would be very inconvenient, and even dangerous, to respire for any length of time, and which has discouraged many persons who tried to use it; the second is, the danger of weakening the cloth. I now also left off mixing any alkali with the oxygenated muriatic acid, as I had practised in the greatest part of my first trials.

"This is nearly the state in which my experiments were, when I made some trials in the presence of the celebrated Mr Watt. A single view sufficed for a philosopher whose genius has been exercised so long upon the arts. In a short time Mr Watt wrote to me from England, that even in the first operation he had bleached five hundred pieces of cloth at Mr Grigor's, who has a large bleaching-ground at Glasgow, and who continues to make use of the new process. In the mean time M. Bonjour, who had hitherto assisted me in my experiments, and who joins great sagacity to a most extended knowledge of chemistry, associated himself with Mr Constant, at Valenciennes, in order to form an establishment in that city."

M. Caillau made a great number of experiments at Paris respecting this new mode of bleaching; but the greatest part of these experiments was made upon cotton, which is more easy to bleach, and does not require leys so often or so strong as flax or hemp. He also went to St Quentin, to perform the operation upon the cloth of that country; but he found that all the cloths, which he had bleached to the satisfaction of the manufacturers, became again of a reddish colour when they were

Bleaching. were expofed to a common ley, or even when they were left for fome time in a warehoufe. Several fimilar complaints were made by other perfons; and M. Berthollet himfelf had obferved the fame thing in his own experiments. M. Bonjour, however, and M. Welter, affirmed that the cloth which they had bleached preferved its colour perfectly. M. Berthollet foon found, that the imperfection in his bleaching was owing to the manner in which he had ufed the leys. "I had contented myfelf (fays he), in thofe trials on fmall pieces which I made in my laboratory, to pour the hot alkaline folution into a veffel where I placed the pieces; it there became cool very rapidly, and therefore did not act with fufficient power; but when I let thefe pieces remain in the liquor, which I kept nearly in a boiling heat during the fpace of two or three hours, they were then no longer fubject to the above mentioned defects: it was therefore merely the weaknefs of the leys which had occafioned the accidents which were experienced by Meffrs Caillau, Décroifille, and myfelf. It is neceffary that the colour of the cloth fhould not be changed by the laft ley, and this is the fureft mark that the bleaching is finifhed; neverthelefs, after this laft action of the ley, it is proper to put the cloth, for a few moments, in the bleaching liquor.

Ann. de Chym. II. 158.

"After this laft immerfion, it is neceffary to plunge the cloth in four milk, or in water acidulated with fulphuric acid. I do not know the moft convenient proportion of fulphuric acid; but it appeared to me that we might fuccefsfully, and without danger, make ufe of one part, in weight, of this acid to fifty of water. We muft keep the cloths during about half an hour in this liquor warmed; after which it is proper to fqueeze them well, and plunge them directly into common water; for if the evaporation fhould take place, the fulphuric acid, becoming thereby concentrated, would corrode them. The cloths being then well wafhed, require only to be dried and dreffed in the ordinary manner, according to their different forts.

"It is of the utmoft importance to take care that the water is not too ftrongly impregnated with the fulphuric acid.

"The bleaching of cotton cloth is much eafier and fhorter; two leys, or at moft three, and as many immerfions in the bleaching liquor, are fufficient for them. As they are bleached fo eafily, it is advantageous, when there are flaxen, hempen, and cotton cloths, to be bleached, to referve for the cotton the liquors which have been previoufly weakened by the cloths of flax or hemp; for it is economical to exhauft the liquors as much as poffible, and thofe which are confiderably weakened ftill fuffice for the cotton, although they have fcarcely any action upon hemp or flax.

"Thread, in the common way of bleaching, is attended with a far greater number of difficulties than cloth; becaufe of the immenfe number of furfaces which it is neceffary to prefent fucceffively to the action of the atmofphere. Some part of thefe difficulties occur in bleaching with the oxygenated muriatic acid; neverthelefs, in the end, it is more advantageous with refpect to thread than with refpect to cloth. Mr Welter has formed at Lifle, with two partners, an eftablifhment for bleaching thread with great fuccefs, and he has already begun fome others. He has found that ten or twelve leys, and as many immerfions, are required for fome forts of thread; and, that the thread may be furrounded with the liquor, it is neceffary to place it, quite loofely, in a bafket, which permits the liquor to penetrate to all its furfaces; when the liquor is much weakened, it is ftill fit to be ufed for the bleaching of cotton.

"I had, in the beginning of my experiments, tried whether the vapour would not be preferable to the oxygenated muriatic acid in a liquid ftate, and I obferved that it bleached with greater quicknefs; but, whatever precautions I employed, it appeared to me that a confiderable lofs of it took place; that thofe parts of the cloths which were the moft expofed to it were fubject to be weakened; and that it was more difficult to obtain an equal whitenefs throughout.

"To prevent all the accidents which may refult from the liquor acting with too great power, it is important to have a means of meafuring its force. M. Decroifille thought of ufing, for that purpofe, a folution of indigo in fulphuric acid. He takes one part of indigo, reduced into fine powder, and eighteen parts of concentrated fulphuric acid; this mixture is put into a matrafs, which is kept, during fome hours, in a water-bath; when the folution is finifhed, it is diluted with a thoufand parts of water. To try the power of the oxygenated muriatic acid, one meafure of this folution is put into a graduated glafs tube, and fome of the liquor is gradually added to it, until the colour of the indigo is deftroyed. We muft firft determine how many meafures of a liquor, the goodnefs of which has been afcertained by experiments made upon cloth, are neceffary to deftroy the colour of one meafure of the folution of indigo, and this number will ferve to eftimate the refpective ftrength of all the liquors which it may be neceffary to compare with it. M. Watt employs, in the fame manner, a folution of cochineal."

5 Method of procuring the acid for bleaching.

M. Berthollet recommended the following method of procuring the oxy-muriatic acid: "If we have good oxyd of manganefe, formed in fmall cryftals, and containing but little extraneous matter, the proportions of the fubftances to be fubmitted to diftillation are the following: Six ounces of calx of manganefe reduced to powder; one pound of common falt, alfo reduced to powder; twelve ounces of concentrated fulphuric acid, or oil of vitriol; from ten to twelve ounces of water.

"When thefe materials are prepared, we muft carefully mix the oxyd of manganefe with the common falt, and introduce the mixture into the diftilling veffel placed upon a fand bath: we muft then pour upon it the fulphuric acid, previoufly diluted (and of which the heat occafioned by its mixture with water is diffipated), and immediately apply to the mouth of the matrafs the tube which is to conduct the gas into the intermediate veffel.—It muft not be forgot, that in this operation the lutes require particular attention.

"The fize of the veffels fhould be fuch, that the diftilling matrafs may be about one-third empty; and, for the quantity above mentioned, the tub fhould hold 100 quarts of water; there fhould alfo be an empty fpace of about 10 quarts, in order that when the gas lodges itfelf in the cavities intended to receive it, the water may have a free fpace to rife in.

"Before the commencement of the operation, the pneumatic tub muft be filled with water. The mixture being made, the gas, which very foon begins to difengage

Bleaching. difengage itfelf, drives out the atmofpherical air which is in the apparatus: when it is judged that the atmofpheric air has paffed into the cavities, it is to be drawn off by means of a bent tube, which is to be introduced fucceffively under each cavity: to drive out the water which has entered into the tube, this laft is to be forcibly blown into. The operation is then fuffered to go on without fire until it is perceived that the bubbles come over but flowly: then a little fire is to be applied, which is not to be haftily increafed at the beginning, but may be gradually augmented, fo that at the end of the operation the matter may be brought to a boiling ftate. It is known to be nearly finifhed when the tube by which the gas is difengaged, and the intermediate veffel, become hot. When the gas is difengaged only in a fmall quantity, the fire may be withdrawn; and when the diftilling veffel retains but a gentle warmth, it is to be unluted, and warm water is to be poured upon the refidue, that it may remain in folution, and thereby be more eafily poured out.

"The operation is longer or fhorter according to the quantity of materials: with that above mentioned, it fhould laft five or fix hours; it is proper not to haften it, that a larger quantity of gas may be drawn off. A fingle perfon is able to manage feveral diftillations at the fame time; to each of which may be given much larger quantities of materials than thofe which have been pointed out.

"The intermediate veffel by degrees becomes filled with a liquor which is pure, though weak, muriatic acid; neverthelefs, we may perform the operation feveral times without extracting it: but when it is fuppofed that there is not fufficient empty fpace, this acid is to be drawn off by means of a fyphon, and, when we have collected a fufficient quantity of it, it may be fubftituted for the mixture of vitriolic acid and common falt in the operation we have defcribed, if we have no other ufe to make of it. That there may pafs but a fmall quantity of muriatic acid, not oxygenated, the firft tube ought to form a right angle, or even an obtufe one, with the body matrafs.

"During the operation, the agitator muft be from time to time put in motion, to favour the abforption of the gas by the water: when it is finifhed, the liquor is of a proper ftrength to ufe in bleaching; or we may put a lefs quantity of water in the tub, and then dilute the liquor according to the proportion already mentioned.

"In this ftate of concentration, although the liquor has a pretty ftrong odour, it neverthelefs is not hurtful, nor even very unpleafant, to thofe who ufe it; it is, however, proper to conduct it into the troughs where the cloths are placed by means of wooden canals, which are to be connected with the faufet or tube which is at the lower part of the tub."—The following is a defcription of the apparatus:

Plate VII. fig. 1. ABCD is a reverberatory furnace, having, on a line with B, many fmall openings in its circumference, to ferve as chimneys; within which, upon a fand-bath *a*, is placed a matrafs *b*, the neck of which ftands out above the furnace, running through the opening D, which is to be clofed with clay. The mouth F, of the neck of the matrafs, is clofed by a cork G, through the middle of which paffes a tube H, which forms a communication between the infide of the matrafs *b*, and the intermediate veffel K, where it alfo paffes through a cork I, which clofes one of the three openings of that veffel. The corks G and I ought to be prepared before-hand, and well fitted to each end of the tube of communication H, which is to be fo difpofed that it may be fitted in immediately after the mixture is made in the matrafs.

The intermediate veffel K is about an eighth part full of water; into it is plunged the tube of fafety L, to prevent danger from regurgitation. This tube ought to be fo high, that the weight of the water which enters into it, by the preffure of the gas, may be great enough to caufe the gas to pafs into the pneumatic tub NOP, by the tube of communication M, which is plunged therein, and reaches to the bottom, where it is bent horizontally, fo that the gas may be emitted under the firft of the three wooden, or (if they can be procured) ftone-ware, cavities, or receivers, which are placed in the infide of the tub, one above the other. O is a handle which ferves to turn the agitator E, the movement of which facilitates the combination of the gas with the water. P is a fpigot and faufet to draw off the liquor.

4 Method of bleaching. It is neceffary to prepare the cloth by leaving it to foak for 24 hours in water, or, which is better, in fome old ley. Afterwards it fhould be fubmitted to the action of one or two good leys; becaufe all the colouring part which may be extracted by the leys would elfe, without any advantage, confume a part of that liquor which it is important to be as fparing of as poffible. After this, the cloth is to be carefully wafhed; then it is to be placed in the troughs, without any part being preffed or confined, in fuch a manner that it may be thoroughly impregnated with the liquor which is to run thereon. The troughs, as well as the tub, ought to be conftructed without iron; for that metal, being rufted by the oxygenated muriatic acid, would produce iron moulds, which could not be taken out but by means of falt of forrel.

The firft immerfion ought to be longer than the others; it may be continued for three hours, after which the cloth is to be taken out; it is to be again fubmitted to the action of ley, and then placed in a trough, that frefh liquor may be poured thereon: it is fufficient that this immerfion, and the following ones, continue half an hour. When the cloth is taken from the trough, the liquor is to be wrung out, it is to be again fubmitted to the ley, and afterwards to frefh immerfions. The fame liquor may ferve until its ftrength is exhaufted: when it is much weakened, there may be fome frefh liquor added to it. When the cloth appears white, except fome black threads and the lifts, it is to be impregnated with black foap, and then ftrongly rubbed: after which it is to be fubmitted to the laft ley and the laft immerfion. We cannot determine what number of leys and immerfions may be neceffary, becaufe it varies according to the nature of the cloth: neverthelefs, the limits of this number are between four and eight for linen or hempen cloths.

The manufacturers at Javelle, to whom M. Berthollet had communicated this procefs, foon after publifhed, in different journals, that they had difcovered a particular liquor which had the property of bleaching cloth by an immerfion of fome hours only. The change they had made in the procefs performed in their prefence, confifted

Bleaching. consisted in putting some alkali into the water which receives the gas; this enables the liquor to become much more concentrated, so that it may be diluted with several times its own quantity of water before it is used.

" These are the proportions which yielded me (says Berthollet) a liquor similar to the pretended Javelle ley; two ounces and a half of common salt, two ounces of sulphuric acid, six drachms of calx of manganese, and, in the vessel where the gas is to be concentrated, one pound of water, and five ounces of potash, which should be dissolved in the water. The Javelle liquor has a somewhat reddish appearance, occasioned by a small quantity of manganese, which either passes in the distillation, because an intermediate vessel is not used, or exists in the potass; most kinds of which contain it, as I have well convinced myself."

" This liquor may be diluted with from ten to twelve parts of water; and, after this, it bleaches more speedily than the liquor itself: but without speaking of the imperfections of the method which is described in the publications from Javelle, and which can only suffice for cotton, we are not able to bleach near the same quantity of cloth with the oxygenated muriatic acid combined in this manner with an alkali, as might be bleached with the same quantity of that acid mixed with water alone; because there is formed a portion of that neutral salt which is known at present by the name of oxygenated muriate of potass, and in which the oxygen becomes concentrated. Now all the oxygen which enters into the composition of this salt is rendered useless for bleaching; because the oxygenated muriate of potash does not destroy colours."

This method of bleaching was very soon adopted in Britain, and is now almost universal among bleachers. A great many changes have been made in the process; one of the most important of which is substituting lead vessels for wooden ones, which, besides weakening its action exceedingly, were very soon destroyed by the acid. We believe, too, that the bleachers very generally add some alkali to the acid, notwithstanding the strong objections which Mr Berthollet has made to that manner of bleaching.

This method of bleaching has been found to answer remarkably well: the only objection that has been made to it is, that the cloth is apt to be weakened. And this, no doubt, must be the case, if care be not taken to prevent the acid from being too much concentrated; but we have little doubt that, with a sufficient degree of caution, it will prove as safe as any other whatever; and, in point of expedition, there cannot surely be any comparison drawn between the old mode of bleaching and the new.

5 Theory of bleaching.

It remains for us now to consider, whether the new discoveries in chemistry do not throw some rays of light upon the theory of bleaching; for it is only by perfecting the theory that we can advance with certainty in our practical improvements.

It has been already observed, in the article BLEACHING (*Encycl.*), that cloth, after being bleached, was a good deal lighter than it had been before the operation: It follows, therefore, that it must have been deprived of something during the bleaching. Cloth bleached by means of the oxy-muriatic acid likewise undergoes a loss of weight; so that, in all probability, both modes act in precisely the same manner.

If raw linen or thread be boiled in a solution of caustic alkali, properly diluted, it gives out something which tinges the ley of a deep brown, and at the same time the alkali loses its causticity. If the linen be boiled in another similar solution, it communicates the same colour, and even a third may be slightly tinged; but after this, alkalis, unless so much concentrated as to injure the texture of the cloth, have no effect on it whatever. If the linen be now plunged into oxy-muriatic acid, properly prepared, and allowed to remain till it begins to become white, and then plunged into an alkaline ley, the alkali loses its causticity, and assumes the same deep colour that the first ley did. Here, then, we have two alkaline solutions; the one saturated with colouring matter before the action of the oxy-muriatic acid on the linen, the other after it. When these solutions are saturated with an acid, a yellow coloured precipitate is obtained, which when dried assumes the appearance of a black powder. Precisely the same substance is obtained from both solutions. This colouring matter is almost insoluble in water. Pure or caustic potass dissolves about double its own weight of it; carbonate of potass not so much.

Hence we see the use of alkalis in bleaching. The colouring matter is not soluble in water, but part of it is soluble in alkali. However, after the alkali has exhausted all its power, the linen is not white: colouring matter, therefore, exists in it, which alkalis cannot act upon. But after being plunged in oxy-muriatic acid, it also becomes soluble in acids. Here, then, is the use of that acid in bleaching—it communicates something to the colouring matter which renders it soluble in alkali. This something, we have already seen, is oxygen. It follows, therefore, that before the greater part of the colouring matter of linen can be extracted by alkalis, it must be combined with oxygen. It is in producing this combination that the use of the exposure to the sun and air consists; and it is because the oxy-muriatic acid produces it almost instantaneously, that the new mode of bleaching is so much more expeditious than the old.

If into the alkaline solution of the colouring matter lime-water be poured, there takes place a copious precipitate, which consists of the lime and colouring matter combined. Lime, therefore, has a stronger affinity for the colouring matter than alkali has: and as the compound of lime and the colouring matter is not very soluble in water, lime-water might be used to deprive the alkaline ley of the colouring matter which it has imbibed; after which it might be used again. Care, however, must be taken that no lime-water remains in the ley; otherwise it might precipitate and fix the colouring matter in the linen, after which it would be very difficult to remove it.

From an alkaline ley, saturated with the colouring matter of linen yarn, Mr Kirwan, by means of muriatic acid, precipitated the colouring matter. He found it to possess the following properties: When suffered to dry for some time on a filter, it assumed a dark green colour, and felt somewhat clammy like moist clay. " I took (says he) a small portion of it, and added it to 60 times its weight of boiling water, but not a particle of it 6 Nature of the colouring matter of linen. *Irish Trans.* 1789.

Bleaching. it was diffolved. The remainder I dried in a fand heat: it then affumed a fhining black colour, became more brittle but internally remained of a greenifh yellow, and weighed one ounce and an half.

"By treating eight quarts more of the faturated ley in the fame manner, I obtained a further quantity of the greenifh depofit; on which I made the following experiments:

"1ft, Having digefted a portion of it in rectified fpirit of wine, it communicated to it a reddifh hue, and was in a great meafure diffolved: but by the affufion of diftilled water the folution became milky, and a white depofit was gradually formed; the black matter diffolved in the fame manner.

"2dly, Neither the green nor the black matter was foluble in oil of turpentine or linfeed oil by a long continued digeftion.

"3dly, The black matter being placed on a red-hot iron, burned with a yellow flame and a black fmoke, leaving a coaly refiduum.

"4thly, The green matter being put into the vitriolic, marine, and nitrous acids, communicated a brownifh tinge to the two former, and a greenifh to the latter, but did not feem in the leaft diminifhed.

"Hence it appears, that the matter extracted by alkalis from linen yarn is a peculiar fort of refin, different from pure refins only by its infolubility in effential oils, and in this refpect refembling lacs. I now proceed to examine the power of the different alkalis on this fubftance. Eight grains of it being digefted in a folution of cryftallized mineral alkali, faturated in the temperature of 60°, inftantly communicated to the folution a dark brown colour; two meafures (each of which would contain 11 pennyweights of water) did not entirely diffolve this fubftance. Two meafures of the mild vegetable alkali diffolved the whole.

"One meafure of cauftic mineral alkali, whofe fpecific gravity was 1,053, diffolved nearly the whole, leaving only a white refiduum.

"One meafure of cauftic vegetable alkali, whofe fpecific gravity was 1,039, diffolved the whole.

"One meafure of liver of fulphur, whofe fpecific gravity was 1,170, diffolved the whole.

"One meafure of cauftic volatile alkali diffolved alfo a portion of this matter."

The colouring matter of cotton is much more foluble in alkali than that of linen; hence the greater facility with which cotton is bleached.

From thefe obfervations, the great importance of alkalis in bleaching, and the neceffity of regulating the ftrength, and afcertaining the purity, of the leys made ufe of, muft be apparent. Manufacturers, therefore, lie under very great obligations to Mr Kirwan, who has lately examined the alkaline matters ufed in bleaching with his ufual accuracy and abilities. The refult of his experiments was as follows:

Irifh Tranf. 1789.

Table of the quantity of mere alkali in 100 Avoirdupois pounds of the following fubftances.

One hundred lbs.	*Mineral Alkali.*
Cryftallized foda	20 lbs.
Sweet barilla	24
Mealy's cunnamara kelp	3,437
Ditto defulphurated by fixed air	4,457
Strangford kelp	1,25

One hundred lbs.	*Vegetable Alkali.*
Dantzic pearl afh	63,33 lbs.
Clarke's refined afh	26,875
Cafhup	19,376
Common raw Irifh weed-afh	1,666
Ditto flightly calcined	4,666

When linen is allowed to remain for fome time in oxy-muriatic acid, it becomes white. It is evident, then, that when the colouring matter of linen is faturated with oxygen, it becomes colourlefs: But linen bleached in this manner very foon becomes yellow, efpecially when expofed to heat. Berthollet, to whofe ingenious experiments and obfervations we are indebted for the greater part of the above remarks, has given the following explanation of the caufe of this change: He diftilled the colouring matter of linen, and obtained a thick oil, a little ammonia, and $\frac{24}{100}$ of carbon remained behind. The oil contained carbon; and he fuppofed that carbonic acid gas, and carbonated hydrogen gas, were difengaged. He concluded in confequence, that one-third of this colouring matter was carbon. The other ingredient in the oil was hydrogen; for Lavoifier has proved that oil is compofed of oxygen and hydrogen. The colouring matter of linen, then, is compofed principally of carbon and hydrogen.

Oxygen combines with hydrogen at a lower temperature than it does with carbon; for if a confiderable quantity of oxy-muriatic acid be mixed with a folution of fugar (a fubftance which confifts chiefly of carbon and hydrogen), and the liquor be evaporated, there remains behind little elfe than carbon, the hydrogen having combined with oxygen and formed water, which had paffed off in the form of vapour. Now, whenever a quantity of hydrogen is feparated from a body principally compofed of hydrogen and carbon, that body affumes a brown or yellow colour, becaufe the carbon becomes predominant; and this colour becomes the deeper the greater the proportion of the carbon is, compared to that of the hydrogen; and at laft, when nothing but carbon remains, it becomes quite black.

It is probable, then, that when the oxy-muriatic acid renders linen white, a quantity of oxygen has combined with the colouring particles, but that this oxygen gradually enters into a combination with the hydrogen, and forms water which paffes off; that then the carbon becomes predominant, and the linen in confequence affumes a yellow colour.*

7 Bleaching of wool and filk.

The fame method does not fucceed in bleaching wool and filk which anfwers for linen and cotton. One would be difpofed to think that thefe fubftances are bleached rather by lofing oxygen than by abforbing it. Wool, for inftance, is rendered white very quickly when expofed to the fumes of fulphurous acid, which we know has a ftrong affinity for oxygen, and foon faturates itfelf with it. But what paffes during the whitening of animal matters has never yet been properly enquired into, though it would not only greatly elucidate *bleaching*, but *dying* likewife, and throw much light upon fome of the obfcureft parts of chemiftry. A great improvement, however, has lately been made by M. Baumé in the manner of bleaching filk. Of this improvement we fhall proceed to give an account.†

Before the filk is wound off the cocons in which the filk worms are inclofed, it is neceffary to kill the infects,

* *Ann. de Chym.* VI. 210.

† See the memoir in the *Ann. de Chym.* xvii. 156, and abridged in *Nicholfon's Journal*, I. 32, from which laft we have taken our account of it.

Bleaching. fects, otherwife they would in all probability eat thro' it and deftroy it. This is commonly done by expofing the cocons, properly wrapped up, for two hours to the heat of about 158 degrees of Fahrenheit in an oven; after which they are kept for a certain time in a mafs to preferve their heat, and effectually deftroy fuch of the infects as might have efcaped the power of the oven. The effect of this procefs is, that the filk is hardened, and is more difficult to wind off than before. Hence the product of filk is lefs by one-ninth part in quantity, and inferior in quality to what might have been obtained by winding off without this previous baking. Mr Baumé, not only from thefe views, but likewife becaufe the filk which has not been baked proves fufceptible of a greater luftre, was induced to deftroy the cryfalis by fpirit of wine. For this purpofe he difpofes them in a wooden box in a ftratum fix inches deep: upon each fquare foot half a pint of fpirit of wine is to be fprinkled with a fmall watering pot made for that purpofe. The liquid is to be equally diftributed, but it is not neceffary that all the cocons fhould be wetted. They are then to be mixed by hand. In the next place another ftratum is to be formed over the firft, nearly of the fame depth, which is to be fprinkled and treated as before. By this method of proceeding, the box becomes filled, and muft then be covered, and left for 24 hours, during which time they become fpontaneoufly heated to about 100 degrees, and the vapour of the fpirit of wine exerts itfelf with wonderful activity. After this treatment they muft be fpread out to dry, which happens in a fhort time, and is abfolutely neceffary previous to winding off.

8

New mode of whitening filk.

The fpirit of wine to be ufed in this operation ought to be of the fpecific gravity .847, at the temperature of 55 degrees. It is of the greateft importance to ufe that fpirit only which has been kept in veffels of glafs, of tinned copper, or of pure tin, Leaden veffels are abfolutely to be rejected; wooden veffels tinge the fpirit, which gives the filk a degree of colour of confiderable permanency, and very inimical to the bleaching procefs.

The filk is wound off upon a reel, while the cocons are kept immerfed in water almoft boiling. Upon this part of the procefs M. Baumé remarks, 1ft, That the dead cocons muft be feparated. Thefe are known by the brown or black fpots on their furface. 2. That well water, which on account of its clearnefs is almoft univerfally ufed in the filk manufactories, moftly contains nitre, and is extremely prejudicial to the bleaching procefs. The prefence of nitrous acid gives a yellow colour, which refifts bleaching and even fcouring; he therefore recommends river-water. 3. In fome countries a fmall quantity of alum is ufed. Neither this nor any other faline fubftance is of the leaft advantage to the colour, beauty, or quality of the filk.

At the four places of contact of the filk upon the reel, all the threads ftick together. It is abfolutely neceffary that this fhould be remedied. The method confifts in foaking the filk in a fufficient quantity of warm water, at about 90 degrees, for about two hours; after which the threads are to be feparated by opening the hanks upon a pin, and lightly rubbing the parts which cohere. When the filk is dry it is to be loofely folded in its original form, and is ready for bleaching.

The filk while wet is foft, and part of its gummy matter is in fuch a ftate, that its threads would readily adhere, if wrung while warm for the purpofe of clearing it of the water. After fuch improper treatment there would be no other remedy than to foak it again in warm water. Bleaching.

The apparatus for bleaching the filk confifts of a ftone-ware veffel, nearly of a conical form, capable of holding about 12 gallons, having a large opening at the one end, and a fmaller of about an inch diameter at the other end. Common pottery cannot be ufed in this operation, becaufe it is foon rendered unferviceable by the action of the muriatic acid, and the ftone-ware itfelf is not very durable. This veffel muft be carefully examined, to afcertain that it does not leak in the flighteft degree; after which the infide is to be rubbed with a pumice-ftone, to clear it of afperities which might break the threads. A cover of the fame material is to be fitted on by grinding; and the fmaller aperture, which in the ufe is the loweft, is to be clofed with a good cork, in the middle of which is thruft a fmall glafs tube about a quarter of an inch in diameter; this is likewife ftopped with a cork, excepting at the time when it is required to draw off the liquid contents of the jar. A fmall perforated falfe bottom is placed within the veffel, to prevent this tube from being obftructed.

Six pounds of yellow raw filk are to be difpofed in the earthen pot; upon this is to be poured a mixture, previoufly made, of 48 pounds of fpirit of wine of the fpecific gravity .867, with 12 ounces of very pure marine acid, abfolutely exempt from all prefence of nitrous acid, and of the fpecific gravity 1.114. The pot is then to be covered, and the whole left in digeftion till the following day, or until the liquor, which at firft affumes a fine green colour, fhall begin to affume that of a dufky brown.

The acidulated fpirit is then to be drawn off, clean fpirit of wine poured upon the filk, and drawn off repeatedly until it paffes colourlefs. The filk is then fuffered to drain without ftirring it. In this ftate it is ready for a fecond infufion.

Forty-eight pounds of fpirit of wine, acidulated with 12 ounces of marine acid, is now to be poured on the filk, and the whole fuffered to remain for 24 hours or longer, until the filk becomes perfectly white. The time required for this fecond infufion is commonly longer than for the firft: it fometimes amounts to two, three, or even fix days, according to circumftances, particularly the temperature and the nature of the filk. Silk which has been in the oven is in general more difficult to bleach.

When the filk has thus obtained its utmoft degree of whitenefs, the acidulated fpirit is to be drawn off into a feparate veffel. This fluid is but flightly coloured, and may be ufed again in the firft infufion of other yellow filk, with the addition of fix ounces more of marine acid. The receiving veffel is to be removed, and another clean veffel fubftituted in its place. The filk is then fprinkled with clean fpirit, and occafionally preffed down with the hand. As foon as the fpirit of wine comes off abfolutely colourlefs, a third infufion is to be made by pouring upon the filk 48 pounds of the pure fpirit without acid, which is to remain till the following day: it is then to be drawn off, and referved for wafhing other filk after the firft infufion.

After the filk has been left to drain, and affords no more fpirit, it ftill retains its own weight of that fluid.

Bleaching.

This is recovered by ſprinkling the ſilk with a ſmall quantity of very clear river-water at a time. While the water applies itſelf and ſubſides along the ſilk, it drives the ſpirit of wine before it, ſo that the firſt portions which flow from the tube are ſcarcely diminiſhed in ſtrength. The addition of water is to be continued until nothing but mere water comes off below.

In this ſituation the ſilk is found to be well bleached, but ſtill retains a portion of marine acid ſufficient to render it harſh to the touch, and after a time brittle. It muſt be waſhed off with water. The beſt method is to put the ſilk looſely into a coarſe woollen bag, which is to be ſecured looſely in another cloth like a ſmall bed or pillow, then placed in a baſket, and left in a running ſtream for five or ſix hours; but where the convenience of a ſtream is wanting, the earthen pot containing the ſilk is to be covered with a cloth, and water pumped through it for five or ſix hours, or until that which iſſues from the lower aperture gives no red colour to the tincture of turnſol. At this period the lower opening is to be cloſed, and the veſſel filled with water, which muſt be changed once or twice in 24 hours.

Though the mineral acids are the moſt powerful and deſtructive of all ſaline ſubſtances, yet they may be applied to ſilk when diluted with ſpirit of wine in very conſiderable doſes. In trials made to aſcertain the maximum, two ounces of marine acid were added to one pound of ſpirit of wine, without altering the ſilk. Two drams of marine acid cauſe a very perceptible alteration in one pound of ſilk.

Spirit of wine which has been mixed with nitrous acid cannot be uſed in bleaching, even though afterwards rectified upon an alkali, becauſe it ſtill retains a portion of nitrous gas. Pure ſpirit of wine without acid extracts a fine yellow colour from ſilk, which does not ſeparate for years, even though expoſed to the ſun's light. Yellow ſilk, expoſed to the ſun, loſes its colour in a ſhort time. The acidulated ſpirit which has been uſed in the infuſion of ſilk, is changed by expoſure to the ſun, but not in ſuch a manner as to be rendered fit for uſe a ſecond time. In order to obtain a beautiful white colour, it is eſſential that the ſilk ſhould be immerſed in a large quantity of the fluid, eſpecially at the firſt infuſion. Without this management it would become neceſſary to make three infuſions in the acidulated ſpirit. When the firſt infuſion is well managed, the ſilk will have loſt all its yellow colour, and become conſiderably white, at the ſame time that the liquor will have begun to change colour a little. As long as it continues of a fine green, it is certain that it has not exhauſted its whole action upon the ſilk. The duration of this firſt infuſion may be longer or ſhorter, without inconvenience, according to the temperature. When the temperature is at 77 of Fahrenheit, the firſt infuſion is often made in 10 or 12 hours. In ſmall experiments the heat of the atmoſphere may be ſupplied by the water bath; in which caſe, all the infuſions are eaſily made in the courſe of a day.

When the firſt infuſion is finiſhed, and the liquor drawn off, the ſilk appears greeniſh: the ſubſequent waſhings in ſpirit of wine clear it of the liquor it retained. This ſprinkling ſhould be made with the watering pot, otherwiſe the quantity poured will be greater, and the management more waſteful.

Pieces of gauze and entire garments of ſilk have been ſucceſsfully bleached in this way.

The fineſt natural white ſilks are rendered infinitely whiter by this proceſs. Spirit of wine alone has the property of depriving yellow ſilk of its colour, which it brings to the ſtate of the naturally white ſilk. In this ſtate the ſilk is diſpoſed to acquire a greater degree of brightneſs by a ſingle infuſion in the acidulated ſpirit. This proceſs has its advantages over the other, to which it is alſo inferior in certain reſpects; concerning neither of which the author has entered into any detail.

The colouring matter was found to be a reſin perfectly animalized, affording by diſtillation the ſame products as other animal matters, and the concrete volatile alkali.

Silk whitened by ſcouring may be dried freely in the air without affecting its luſtre. This is not the caſe with the ſilk bleached in the gum: if it be left at liberty to dry in the air, it reſembles white flax without any luſtre. The beauty of this ſilk conſiſts in its ſhining brilliancy; to ſecure which it muſt be dried in a ſtate of tenſion. Mr Baumé has contrived a ſimple machine for this purpoſe. It conſiſts of a ſtrong ſquare frame of wood ſtanding upright upon feet: the upper horizontal bar is ſix feet long, and has ſix iron pins driven through it at equal diſtances, ſo as to project on each ſide for the purpoſe of receiving twelve bobbins. The lower horizontal bar is moveable up and down in a mortice, by means of a ſcrew at each end: it is furniſhed with ſix holes, adapted to receive as many pins to correſpond with thoſe above. The ſkains of ſilk are to be dreſſed and arranged upon wooden pins, as they are taken out of the ſack from waſhing. As ſoon as there are twelve together, they are to be wrung with a ſtaff; after which the ſkains are to be hung one by one upon as many bobbins put upon the upper pins of the ſquare frame. Another bobbin with tails is to be inſerted in the lower loop of the ſkain, and faſtened to the correſponding pin of the lower bar, by means of a ſtrap and hook, which need not be deſcribed to ſuch as are ſlightly acquainted with mechanical objects. When the machine is thus ſupplied with ſkains on both ſides, the lower bar of the frame is to be preſſed down by the ſcrews until the ſilk is moderately ſtretched. When it is dry, the ſcrews are to be equally ſlackened, the ſkains taken off, and folded with a ſlight twiſt, that they may not be become entangled.

To complete the deſcription of this proceſs, it only remains to ſhow how to recover the alcohol, and enſure the purity of the acids made uſe of.

9

Method of recovering the alcohol uſed,

The alcohol which has been uſed in bleaching ſilk is acid, and loaded with colouring matter. In this ſtate it cannot be again uſed. There are two methods of diſtilling it, which have their reſpective advantages and inconveniences.

By the firſt the acid is loſt; which is ſaturated with potaſs, in order that the diſtillation may be afterwards performed in a copper alembic. A ſolution of potaſs is to be poured into the acid ſpirit, and ſtirred about to promote the ſaturation. Carbonic acid is diſengaged with ſtrong effervescence from the alkali, and the point of ſaturation is known by the uſual teſt, that the fluid does not redden the tincture of turnſol. The diſtillation is then to be made in the copper alembic, and the alcohol reſerved in proper veſſels.

In

Bleaching.

In the second process for distilling without alkali, the acid spirit is distributed into a great number of glass retorts, placed in the sand-bath, on the gallery of a furnace. The first product is scarcely acid; but what follows is more and more so, and must be kept in vessels of glass or stone-ware, which become embarrassing on account of their number. The fluid which remains in the retorts has the colour of beer slightly turbid, and contains the greatest part of the marine acid. It must be poured into one or more retorts, and concentrated by heat gradually applied. The first liquor which comes over is slightly red, turbid, and scarcely acid. This is to be thrown away, and the receivers changed. The succeeding product is the colourless marine acid, of an aromatic smell resembling the buds of poplar. The resin of the silk remains in the retort decomposed by the acid. The marine acid thus obtained is weaker than it originally was; which is in fact of little consequence, as it is pure, and may be safely used, either by increasing the dose proportional to its diminished strength, or by concentrating it if required in the usual way. If this distillation be made in a silver alembic, instead of retorts of glass, and a capital and worm of pure tin be annexed, the alcohol will be obtained so slightly acid as scarcely to redden the tincture of turnsol; but it is sufficiently acid to receive injury if preserved in a copper vessel.

10
And of preparing a pure muriatic acid.

As to the acid, Mr Baumé observes, that the muriatic acid of commerce is unfit for the purpose. It was formerly prepared with the marine salt of the saltpetre manufacturers; and even when it is made with good salt, the decomposition is effected with common vitriolic acid which contains nitrous acid. Marine acid mixed with a small quantity of nitrous acid does not prevent the silk from being beautifully whitened: it even accelerates the process considerably, and in the most satisfactory manner. But the alcohol, every time it is used and rectified, becomes charged with the acid and gas of nitre, which assume the characters of the nitrous anodyne liquor. In this state neither distillations nor repeated rectifications from alkali are sufficient to separate the nitrous matter from the alcohol. Then it is that the success of the operator vanishes, with a degree of rapidity equal to the advances which encouraged his hopes at the commencement.

To purify common sulphuric acid, 100 pounds of it are to be mixed in a large bason of copper with the same quantity of river-water, and stirred with a wooden spatula. The mixture instantly becomes heated to the boiling water point, and a great quantity of red vapour is disengaged, which has the smell of aqua-regia, and arises from the nitric and muriatic acids. When this mixture is made, it is proper to immerse the bason to a suitable depth in a large vessel of water, to hasten the cooling. As soon as it is sufficiently cooled, it is to be drawn off into bottles, and left to become clear during several days. It is in the next place to be decanted, and conveyed into retorts by a syphon funnel, and the rectification proceeded upon until it becomes perfectly white. Towards the end of the operation a small quantity of sulphur sublimes in the neck of the retort. Instead of receivers, a small glass cup is placed beneath the aperture of each retort, in order to facilitate the dissipation of the nitric and muriatic acids. When the acid in the retorts is sufficiently cooled, it is poured a second time into the copper bason, and mixed with 100 pounds of river-water, as at first, and again concentrated in the retorts till it becomes perfectly clear. The muriatic acid is to be disengaged from common salt by the application of this acid in the usual manner.

11
Bleaching paper.

The oxy-muriatic acid is also used very generally for bleaching paper, or rather the stuff out of which paper is made. It has been alleged and we believe with some truth, that since this mode of whitening paper was introduced into this country, the strength of paper is much inferior to what it was formerly. If this be really the case, perhaps it is owing to the use of too concentrated an acid.

We shall finish this article with Mr Chaptal's account of this process, who was the first person that introduced it. "Blotting paper (says he), by being put into oxygenated muriatic acid, is bleached without suffering any injury; and rags of coarse bad cloth, such as are used in the paper manufactories to make this kind of paper, may be bleached by this acid, and will then furnish paper of a very superior quality. I bleached by it an hundred weight of paste, intended to be made into blotting paper, and the increase of value in the product was computed at 25 *per cent.* whereas the expence of the operation, when calculated in the strictest manner, amounted only to 7 *per cent.*

12
Mode of whitening old books.

"The property possessed by this acid, of bleaching paper without injuring its texture, renders it very valuable for restoring old books and smoked prints. The latter, when discoloured to such a degree that the subject of them could hardly be distinguished, were re-established and revived, in so astonishing a manner that they appeared to be new; and old books, soiled by that yellow tinge which time always produces, may be so completely renewed, that one might suppose them to be just come out of the press. The simple immersion of a print in oxgenated muriatic acid (leaving it therein a longer or a shorter time, according to the strength of the liquor (is all that is required for bleaching it; but when a book is to be bleached, some farther precautions are to be used. As it is necessary that the acid should wet every one of the leaves, the book must be completely spread open, and then, by letting the boards of the binding rest upon the sides of the vessel, the paper only will be immersed in the liquor. If any of the leaves stick together, they must be carefully separated, that all of them may be equally impregnated. The liquor takes a yellow tinge, the paper grows white; and after two or three hours the book may be taken out of the liquor, and soaked in clean water, which should be changed from time to time, in order to wash out the acid with which the book is impregnated, and also to deprive it of the disagreeable smell it has contracted.

"The above method, which is the first I made use of, has generally succeeded pretty well; too often, however, the leaves of my books have had a motely appearance, and sometimes several pages were not at all bleached; I was therefore obliged to have recourse to the following more certain process. I began by unsewing the books, and reducing them into sheets; these sheets I placed in divisions made in a leaden vessel; by means of thin slips of wood, so that the leaves when laid flat were separated from each other by very small intervals. I then put the acid into the vessel, pouring it against the side, that the leaves might not be disturbed;

Bleaching ‖ Boar. ed; and when the operation was finished, I drew off the acid, by means of a cock fixed in the bottom of the vessel. I then filled the vessel with clean water, which washed the leaves, and took off the smell of the oxygenated acid. They may then be dried, smoothed, and new bound. In this manner I have restored many valuable books, which had become worthless from the bad state they were in.

13 And prints. "When I had to bleach prints so torn to pieces that they consisted only of fragments fitted together, and pasted upon paper, I was afraid I might lose some of these fragments in the liquor, because they separate from the paper by the softening of the paste; in that case therefore I took the precaution of enclosing the print in a large cylindrical bottle which I turned upside-down, fixing its mouth to that of a vessel in which I had put a mixture proper for disengaging oxygenated muriatic gas. This gas fills the inside of the bottle, and, acting upon the print takes off the stains, ink-spots, &c. while the fragments remain pasted to the paper, and consequently keep their respective places."

BLOCK *Island*, called by the Indians *Manisses*, lies about 21 miles S. S. W. of Newport, and is in Newport co. state of Rhode-Island. It was erected into a township, named *New-Shoreham*, in 1672. This island is 46 miles in length, and its extreme breadth is 38 miles. It has 682 inhabitants, including 47 slaves. It is famous for cattle and sheep, butter and cheese: round the ledges of the island considerable quantities of cod fish are caught. The southern part of it is in N. lat. 41. 8.—*Morse*.

BLOCKLEY, a township in Philadelphia co. Pennsylvania.—*ib*.

BLOCKS (*Encycl.* Plate XCV. fig. 5) *a*, Represents a single block, and *b*, *c*, two double ones of different kinds, without strops; *e*, *f*, two double tackle blocks, iron bound, the lower one, *f*, being fitted with a swivel; *g*, a double iron block with a large hook; *h*, a small block; *i*, a top block: *k*, a voyal block; *l*, a clew garnet block; *m*, the cat block, employed to draw the anchor up to the cat-head. See *Cat-Head*, Encycl.

BLUE HILL, a township in Hancock co. District of Maine, on the W. side of Union River, 344 miles N. E. of Boston, and 13 E. of Penobscot; having 274 inhabitants.—*Morse*.

Blue Hill *Bay*, is formed by Naskeag Point on the W. and Mount Desart Island on the E. It extends northerly up to a mountain on the E. of Penobscot River, which, from its appearance at sea, is called *Blue Hill*. Union River empties into this bay.—*ib*.

Cape or Large Snouted BOAR, a species of the genus Sus, which, according to M. Vaillant, differs from every known species, and has not been accurately described by any writer of natural history. Buffon, indeed, in the Supplement to his History of Quadrupeds, has given a figure of it; but nothing like the head of the animal is discoverable, says our author, in that figure, all its characteristics having been omitted by the draughtsman. M. Vaillant, during his last travels in

Plate VII. Africa, shot a monstrous boar of this species on the banks of Fish-river, and in the country of the *Greater Nimiquas*. He describes it in the following terms: Its snout, instead of being taper and in the form of a proboscis, is, on the contrary, very broad and square at the end. It has small eyes, at a very little distance from each other, level with the surface, and near the top of the forehead. On each cheek a very thick cartilaginous skin projects horizontally, being about three inches long and as many broad. At first sight you would be tempted to take these excrescences for the ears; particularly as the real ears of the animal, sticking as it were to the neck, which is very short, are partly concealed by an enormous mane, the bristles of which, in colour red, brown, and greyish, are 16 inches in length on the shoulders. Directly below these false ears is a bony protuberance on each side, projecting more than an inch, serving the animal to strike with to the right and left. The boar has, besides, four tusks, of the nature of ivory, two in each jaw: the upper ones are seven or eight inches long; very thick at the base, and terminating in an obtuse point, grooved, and rising perpendicularly as they issue from the lips: the lower ones are much smaller, and so close to the upper ones when the mouth is shut, that they appear as one. The head is a truly hideous object. It is scarcely less so than that of the hippopotamus, to which at first view it appears to have a striking resemblance. Systematists, accustomed to view nature only according to rules established by themselves, will be far from acknowledging this animal to be a boar; for, not to mention its large snout, it wants incisive teeth in both jaws. Notwithstanding its wide muzzle, it ploughs up the earth to seek for roots, on which it feeds. It is very active, though large and bulky; running with such speed, that the Hottentots give it the name of the *runner*.

Boar ‖ Bombay.

BOEUF, LE, a place in the N. western corner of Pennsylvania, at the head of the N. branch of French Creek, and 50 miles from Fort Franklin, where this Creek joins the Alleghany; measuring the distance by water. The French fort of Le Boeuf, from which the place has its name, lay about 2 miles E. from Small Lake, which is on the N. branch of French Creek; and from Le Boeuf, there is a portage of 14 miles northerly, to Presque Isle, in Lake Erie; where the French had another fort.

From Le Boeuf, to Presque Isle, is a continued chesnut-bottom swamp (except for about one mile from the former, and two from the latter) and the road between these two places, for 9 miles, 15 years ago, was made with logs, laid upon the swamp. N. lat. 42. 1. W. long. 79. 53. 20.—*ib*.

BOLTON, a township in Chittenden co. Vermont, on Onion River, about 104 miles N. N. E. from Bennington, having 88 inhabitants.—*ib*.

Bolton, a township in Tolland co. Connecticut, incorporated in 1720; and was settled from Weathersfield, Hartford, and Windsor, 14 miles E. from Hartford.—*ib*.

Bolton, a township in Worcester co. Massachusetts; 18 miles N. E. from Worcester, and 34 W. from Boston. It contains 861 inhabitants.—There is a fine bed of limestone in this town, from which considerable quantities of good lime are made yearly.—*ib*.

BOMBAY *Hook*, an island at the mouth of Delaware River about 8 miles long and 2 broad, formed by the Delaware on the eastern side, and Duck Creek and Little Duck Creek on the Maryland side; these are united together by a natural canal. It is proposed to connect Delaware River with Chesapeak Bay,

Bonet || Bonnet.

by a canal from Duck Creek to that bay, through Chester River. The N. W. end of Bombay Hook is about 47 miles from Capes Henlopen and May, from the Hook to Reedy Island is 9 miles.

BONET (Theophilus), was born at Geneva in the year 1620. His parents were able to give him the most liberal education, and his genius directed him to the study of physic; and that he might have every advantage, he attended on the lectures of the most eminent professors in many of the celebrated universities in Europe. In 1643 he was admitted to the degree of M. D. and was for some time physician to the Duke of Longueville. His superior skill in his profession soon brought him into considerable repute; but being seized with an excessive deafness, he was obliged to retire from business when about 60 years of age.

During this retirement he employed himself in collecting all the observations which he had made in a practice of forty years duration, and in arranging them under proper heads. His first publication, which was intitled *Pharos Medicorum*, &c. consists of practical cautions, extracted mostly from the works of Bellonius; and in it he points out many errors which then prevailed in the general practice of physic. Of this work he gave to the world a second edition, considerably improved and greatly enlarged; and in 1687 it was a third time printed at Geneva, under the title of *Labyrinthi medici extricati*, &c.

In 1675 he published *Prodromus anatomiæ practicæ, sive de abditis morborum causis*, &c. This was intended merely as an introduction to a work that soon followed, under the title of *Sepulchretum, sive anatomia practica ex cadaveribus morbo denatis*. In these two publications he has collected a great number of curious observations upon the diseases of the head, breast, belly, and other parts of the body.

In 1682 appeared at Geneva *Mercurius Compitalius, sive index medico-practicus per decisiones, cautiones*, &c. in folio; and in 1684 and 1686 two volumes in folio likewise, intitled *Medicini Septentrionalis collatitia*. This last work is a collection of the best and most remarkable observations in physic which had been then made in England, Germany, and Denmark, which Dr Bonet arranged under proper heads, according to the several parts of the human body. At Geneva, in 1692, was published, in three volumes folio, *Polyalthes, sive Thesaurus medica practicus ex quibuslibet rei medicæ scriptoribus congestus*, &c. and some years before, he gave to the world correct editions of *Theodori Turqueti de Maerne tractatus de arthritide, una cum ejusdam aliquot consiliis*; and of *Jacobi Rohaulti tractatus physicus e Gallico in Latinum versus*. This laborious and useful author died of a dropsy on the 29th of March 1698.

BONNET (Charles), was descended from a French family, who being compelled, on account of their religious principles, to emigrate from their native country, established themselves at Geneva in the year 1572. His grandfather was advanced to the magistracy in that city, and adorned by his integrity an eminent station. His father, who preferred the station of a private citizen, paid unremitted attention to the education of his son, who was born on the 13th of March 1720; and Charles, at a very early period, recompensed his father's assiduity, by the amiableness of his disposition, and the rapid progress he made in general literature. When he was about 16 years of age, he applied himself, with great eagerness, to the perusal of *Le Spectacle de la Nature*; and this work made such a deep impression on his mind, that it may be said to have directed the taste and the studies of his future life. What that publication had commenced, was confirmed by the work of *La Pluche*; but having accidentally seen the treatise of *Reaumur* upon insects, he was in a transport of joy. He was very impatient to procure the book; but as the only copy in Geneva belonged to a public library, and as the librarian was reluctant to entrust it in the hands of a youth, it was with the utmost difficulty that he could obtain his end.

Bonnet.

By the possession of this treasure, our assiduous youth was enabled to make several new and curious experiments, which he communicated to Reaumur himself; and the high applause he gained from so great a naturalist added fresh vigour to his assiduity.

In compliance with his father's desires, he applied himself, though with much reluctance, to the study of the law. The works of *Burlamaqui* pleased him the most, on account of the perspicuous and philosophic manner in which the subject was treated: the institutes of *Heineccius* gave him some courage also, as he perceived order and connection; but the Roman law terrified him as the *hydra of Lerna*. Notwithstanding his application to these authors, he still continued attached to natural history, and was very active in making experiments. The experiments which demonstrate that tree-lice propagate without copulation, was communicated by Reaumur to the Academy of Sciences; and this circumstance occasioned an epistolary correspondence between M. Bonnet and that great naturalist. This was doubtless very flattering to a youth of twenty years. The letter of Reaumur was accompanied with a present of that very book which he had borrowed with so much difficulty two years before.

Animated by such distinguished marks of approbation, he diligently employed every moment he could steal from the study of jurisprudence to the completion of his natural history of the tree louse; to experiments on the respiration of catterpillars and butterflies, which he discovered to be effected by stigmata, or lateral pores; to an examination of the construction of the tænia or tap-worm; in frequent correspondence with Reaumur; and in assisting Trembley in his discoveries and publication concerning millepedes, &c. Having in the year 1743 obtained the degree of doctor of laws, he relinquished a pursuit which he had commenced with so much reluctance. In the same year he was admitted a fellow of the Royal Society, to which he had communicated a treatise on insects.

Bonnet being now liberated from his other pursuits, applied himself, without intermission, to collecting together his experiments and observations concerning the tree-louse and the worm, which he published in 1744 under the title of *Insectology*. This work acquired deserved approbation from the public, and was honoured by the commendation of the celebrated B. de Jussieu. He was reproached, however, in a periodical publication, with having paid too little attention to the delicacy of his reader; though his patience and accuracy were acknowledged to be deserving of praise. Such unremitted application and labour could not fail of becoming injurious to his health. Inflammations, nervous

fever,

Bonnet. fever, fore eyes, &c. compelled him to relinquifh the ufe of the microfcope and the ftudy of infects. This prevention was fo extremely mortifying to a man of his tafte and activity of mind, that he was thrown into a deep melancholy, which could only be fubdued by the refolution infpired by philofophy, and the confolations of religion: thefe gradually roufed him from a dejected ftate of mind. About the end of the year 1746 our philofopher was chofen member of the Literary Inftitution at Bologna, which introduced him to a correfpondence with the famed Zanotti, who may be deemed the Fontenelle of Italy.

In the year 1747 he undertook a very difficult work on the leaves of plants; which, of all his publications in natural hiftory, bore the ftrongeft marks of originality, both with refpect to the manner in which his experiments were made, and the difcoveries refulting from them. His extreme attachment to natural hiftory gradually led him to a ftudy of a very different nature; fpeculative philofophy now engaged his whole attention. The firft fruits of his meditations in this department was his *Effay on Pfychology*. In this work the principal facts obfervable in human nature, and the confequences refulting from them, are ftated in a concife and confpicuous manner. He contemplated man from the firft moment of his exiftence, and purfued the developement of his fenfes and faculties from fimple growth up to intelligence. The work, which was publifhed without his name, met with great oppofition, and was criticifed with feverity; but the cenfures were directed more againft his expreffions than his principles; nor were they of fufficient importance to impede the general acceptance of the publication.

His analyfis of the mental faculties was fimply a developement of the ideas contained in the preceding work. It engaged his inceffant attention for the fpace of five years; nor was it completed before 1759. It is fomewhat fingular that both he and the Abbé de Condillac fhould have illuftrated their principles by the fuppofition of a ftatue, organized like the human body, which they conceived to be gradually infpired with a foul, and the progreffive developement of whofe powers they carefully traced. In the year 1760 this work was publifhed at Copenhagen, by order and at the expence of Frederick V. and it was followed in 1762 by contemplations on organized bodies. In this the author had three principal objects before him; the firft was to give a concife view of every thing which appears interefting in natural hiftory, refpecting the origin, developement, and reproduction of organized bodies; the fecond was to confute the two different fyftems founded upon the Epigenefis; and the third was to explain the fyftem of Germs, indicate the ground upon which it was founded, its correfpondence with facts, and the confequences refulting from it. This work was received with much fatisfaction by natural philofophers. The Academy of Berlin, which had propofed the fame fubject as a prize queftion for 1761, declared that they confidered the treatife as the offspring of clofe obfervation and profound reafoning; and that the author would have had an indubitable right to the prize, if he had confined his labours to the precife ftatement of the queftion. It muft alfo be recorded, to the honour of the great *Malefherbes*, that he reverfed the interdict which the public cenfor had laid upon this book, under the pretext that it contained dangerous principles. Bonnet.

The Contemplation of Nature appeared in 1764. In this work the author firft enlarged upon the common conceptions entertained concerning the exiftence and perfections of God; and of the order and uniformity obfervable in the univerfe. He next defcends to man, examines the parts of his compofition, and the various capacities with which he is endowed. He next proceeds to the plants; affembles and defcribes the laws of their economy; and, finally, he examines the infects, indicates the principal circumftances in which they differ from larger animals, and points out the philofophical inferences that may legitimately be deduced from thefe differences; and he concludes with obfervations refpecting the induftry of infects. This work being of a popular nature, the author fpared no pains in beftowing upon it thofe ornaments of which it was fufceptible. The principles which he thus difcovered and explained, induced him to plan *a fyftem of moral philofophy;* which, according to his ideas, confifted folely in the obfervance of that relation in which man is placed, refpecting all the beings that furround him. The firft branch would have comprehended, various means which philofophy and the medical fcience have difcovered for the prevention of difeafe, the prefervation and augmentation of the corporeal powers, and the better exertion of their force: in the fecond, he propofed to fhew, that natural philofophy has a powerful tendency to embellifh and improve our mind, and augment the number of our rational amufements, while it is replete with beneficial effects refpecting the fociety at large. To manifeft the invalidity of opinions, merely hypothetical, he undertook, in the third place, to examine, whether there were not truths within the compafs of human knowledge, to which the moft fceptical philofopher muft be compelled to yield his confent, and which might ferve as the bafis of all our reafonings concerning man and his various relations. He then would have directed his attention to a firft caufe, and have manifefted how greatly the idea of a Deity and Supreme Lawgiver favoured the conclufions which reafon had drawn from the nature and properties of things: but it is deeply to be regretted that his health, impaired by inceffant labour, would not permit him to complete the defign.

His laft publication was the *Palingenefis*, which treats of the prior exiftence and future ftate of living beings.

Of his publications in natural hiftory, thofe deemed the moft excellent are, his Treatife on the beft Means of preferving Infects and Fifh in Cabinets of Natural Hiftory; a differtation on the Loves of the Plants; fundry pieces on the Experiments of *Spallanzani*, concerning the Reproduction of the Head of the Snail; a Differtation on the *Pipa*, or Surinam Toad; and different Treatifes on Bees.

In the year 1783 he was elected honorary member of the Academy of Sciences at Paris; and of the Academy of Sciences and the Belles Lettres at Berlin.

Much of his time was employed in a very extenfive correfpondence with fome of the moft celebrated natural philofophers and others. Of this number were *Reaumur*, *De Geer* the Reaumur of Sweden, *Du Hamel*, the learned *Haller*, the experimental philofopher *Spallanzani*,

lanzani, *Van Swieten*, *Merian*, and that ornament of Switzerland the great *Lambert*. He entertained, however, the utmoſt averſion to controverſy. He thought that no advantage to be obtained by it could compenſate for the loſs of that repoſe which he valued, with Newton, as the *rem prorſus ſubſtantialem*. He never anſwered remarks that were made to the prejudice of his writings, but left the deciſion with the public; yet, ever ready to acknowledge his errors, he was ſincerely thankful to every one who contributed to the perfection of his works. He was uſed to ſay, that one confeſſion, *I was in the wrong*, is of more value than a thouſand ingenious confutations.

His literary occupations, and the care he was obliged to take of his health, prevented him from travelling. He delighted in retirement, and every hour was occupied in the improvement of his mind. The laſt 25 years of his life were ſpent in the ſame rural ſituation where he had paſſed the greater part of his early days; yet notwithſtanding the purſuit of literature was his ſupreme delight, he never refuſed to ſuſpend his ſtudies, when the good of his country ſeemed to demand his ſervices.

He was choſen in 1752 member of the Grand Council in the republic of Geneva; and he aſſiſted regularly at their deliberations till the year 1768, where he diſtinguiſhed himſelf by his eloquence; his moderation, united with firmneſs; by his good ſenſe and penetration in caſes of difficulty; and by the zeal with which he endeavoured to reclaim his fellow-citizens to that ancient ſimplicity of manners which had been ſo conducive to the welfare of the ſtate, and to the love of virtue, ſo eſſential to the exiſtence of genuine liberty. His conduct, in every caſe, was conſiſtent with his principles. He took no pains to accumulate wealth, but remained ſatisfied with a fortune equal to his moderate wants, and to the exerciſe of his benevolence. The perfect correſpondence between his extenſive knowledge and virtuous deeds procured him univerſal eſteem.

In the year 1788 evident ſymptoms of an *hydrops pectoris* manifeſted themſelves; and from this time he gradually declined. He ſuſtained his indiſpoſition with unremitted cheerfulneſs and compoſure. After various fluctuations, uſual in that complaint, he died on the 20th of May 1793, in the 73d year of his age; retaining his preſence of mind to the laſt moment, adminiſtering comfort to ſurrounding friends and relatives, and attempting to alleviate the diſtreſs of his diſconſolate wife, in whoſe arms he expired.

As a demonſtration of the high value placed upon his labours and talents by the literati, we have only to remark, that he was member of moſt of the learned ſocieties of Europe.

BOOK KEEPING, is an art of which the importance is univerſally known; and as commonly practiſed, it has been ſufficiently explained in the Encyclopædia. But ſince that article was written, a great improvement has been introduced into the art, or rather a new method of book-keeping has been invented, by Mr EDWARD THOMAS JONES, of the city of Briſtol, accountant, who calls it the *Engliſh ſyſtem of book-keeping*; and thinks that by it accounts may be more regularly kept, and errors in accounts more eaſily detected, than by any other method hitherto known. We are much inclined to be of his opinion; and ſhall therefore lay before our readers his deſcription of this method, as we find it in the ſpecification of the patent which was granted to him January 26, 1796.

The Engliſh Syſtem of Book Keeping requires three books, called a *day-book* or *journal*, an *alphabet*, and a *ledger*, which muſt be ruled after the following method, *viz.* the day-book to have three columns on each page, for receiving the amount of the tranſactions; one column of which to receive the amount of debits and credits, one column to receive the debits only, and one column to receive the credits only; or it may be ruled with only two columns on each page, one column to receive the amount of the debits, and one column to receive the amount of the credits. There muſt alſo be on each page of the day-book four other columns ruled, two on the left ſide next the amount of the debits, and two on the right ſide next the amount of the credits, for receiving the letter or mark of poſting, and the page of the ledger to which each amount is to be poſted.

The alphabet need not be ruled at all, but muſt contain the name of every account in the ledger, the letter that is annexed to it as a mark of poſting, and the page of the ledger.

The ledger muſt be ruled with three, four, five, or ſeven columns on each page, as may be moſt agreeable, for receiving the amounts of the different tranſactions entered in the day-book. And the proceſs for uſing theſe books, or making up books of accounts on this plan, is as follows.

When a perſon enters into trade, whether by himſelf or with copartners, he muſt have an account opened with himſelf in the ledger; entering firſt in the day-book, and then to the credit of his account in the ledger, the amount of the property he advances into trade: The account may be headed either with his name only, or elſe called his ſtock-account.

If you buy goods, give the perſon credit of whom you purchaſe; when you ſell goods, debit the perſon to whom ſaid goods are ſold. If you pay money, debit the perſon to whom paid, not only for what you pay, but alſo for any diſcount or abatement he may allow, and give the caſhier credit for the neat amount paid. If you receive money, credit the perſon of whom you receive it, not only for what he pays, but alſo for any diſcount or abatement you may allow, and debit the caſhier for the neat amount received; taking care in theſe entries to have nothing myſterious or obſcure, but merely a plain narrative of the fact, introducing not one uſeleſs word, and avoiding every technical term or phraſe except the words debit and credit, which are full and comprehenſive, and the only terms that are applicable to every tranſaction, and may be affixed to every entry.

But as a hurry of buſineſs will ſometimes take place in almoſt every counting-houſe, which may cauſe the entries to be made to the debit inſtead of the credit of an account in the day-book, and to the credit inſtead of the debit, Mr Jones has endeavoured as much as poſſible to counteract the evil, by having only one column for receiving the amount of every tranſaction, whether debits or credits, at the inſtant of making the entry; and, for the convenience of ſeparating the debits from the credits, previous to poſting, which is neceſſary to prevent confuſion and perplexity, he has two other columns on the fame page; that on the left fide into which the amount of every debit muft be carefully entered, and that on the right for the amount of the credits, which columns muft be caft up once a month. The column of debits and credits of itfelf forming one amount; the column for the debits producing a fecond amount; and the column of credits a third amount; which fecond and third amounts, added together, muft exactly agree with the firft amount, or the work is not done right.

By this means the man of bufinefs may obtain monthly fuch a ftatement of his affairs as will fhow how much he owes for that month, and how much is owing to him; and the debits being added together for any given time, with the value of the ftock of goods on hand, will, when the amount of the credit is fubtracted therefrom, fhew the profits of the trade.

Our author now proceeds to the procefs of pofting; which begins with opening an account in the ledger with every perfon to whofe debit or credit there has been an entry made in the day-book; affixing to each account a letter, which is to be ufed as a mark of pofting. The perfon's name, place of abode, and the folio of the ledger, muft then be entered in the alphabet, with the fame letter prefixed to each name as is affixed to the account in the ledger. Next the page of the ledger on which each account is opened (and which will be feen in the alphabet) muft be affixed to each amount in the day-book, in the column for that purpofe. The date and amount of each debit muft then be pofted in the columns for receiving it in the ledger, on the left or debit fide of that account to which it relates; entering, as a mark of pofting in the day-book, againft each amount, the fame letter that is affixed to the account in the ledger, to which faid amount may be pofted. Obferving that the debits of January, February, March, &c. muft be pofted into the column for thefe months in the ledger, and the credits muft alfo be pofted in like manner, filling up each account in the centre, at the expiration of every month, with the whole amount of the month's tranfactions; thus having in a fmall fpace, the whole ftatement of each perfon's account for the year; in the columns to the right and left the amount feparately of each tranfaction; and in the centre a monthly ftatement.

Having defcribed the procefs of this method of book-keeping, he thus fhews how to examine books kept by this method, fo as to afcertain, to an abfolute certainty, if the ledger be a true reprefentation of the day-book; *i. e.* not only if each tranfaction be correctly pofted, as to the amount thereof, but alfo if it be rightly entered to the debit or credit of its proper account. This examination differs from the modes that have heretofore been practifed, as well in expedition as in the certain accuracy which attends the procefs; it being only neceffary to caft up the columns through the ledger debits and credits, according to the examples given; and the amount of thofe columns, if right, muft agree with the columns in the day-book for the fame correfponding fpace of time. Thefe caftings fhould take place once a month; and if the amounts do not agree, the pofting muft then, but not elfe, be called over; and when the time, whether it be one, two, three, or four months, that is allotted to each column of the ledger is expired, the amount of each column fhould be put at the bottom of the firft page, and carried forward to the bottom of the next, and fo on to the end of the accounts; taking care that the amount in the day-book, of each month's tranfactions, be brought into one grofs amount for the fame time.

But although this procefs muft prove that the ledger contains the whole contents of the day-book, and neither more nor lefs, yet it is not complete without the mode of afcertaining if each entry be pofted to its right account; which may be afcertained by the following method. He has laid down a rule that a letter, which may be ufed alphabetically in any form or fhape that is agreeable, fhall be affixed to each account in the ledger, and the fame letter prefixed to the names in the alphabet, thefe letters being ufed as marks of pofting, and affixed to each account in the day-book as it is pofted; it is only neceffary therefore to compare and fee that the letter affixed to each entry in the day-book is the fame as is prefixed to the fame name in the alphabet; a difference here fhews of courfe an error, or elfe it muft be right.

At the end of the year, or at any other time, when perfons balance their accounts, if there be no objections to the profits of the trade appearing in the books, the ftock of goods on hand at prime coft may be entered in the day-book, either the value in one amount, or the particulars fpecified, as may be moft expedient, and an account opened for it in the ledger, to the debit of which it muft be pofted. The cafting up of the ledger muft then be completed; and when found to agree with the day-book, and the amount placed at the bottom of each column, fubtract the credits from the debits, and it will fhew the profit of the trade; unlefs the credits be the greater amount, which will fhew a lofs. In taking off the balances of the ledger, one rule muft be obferved, and it cannot be done wrong: As you proceed, firft fee the difference between the whole amounts of the credits and debits on each page for the year, with which the difference of the outftanding balances of the feveral accounts on each page muft exactly agree, or the balances will not be taken right. By this means every page will be proved as you proceed, and the balances of ten thoufand ledgers, on this plan, could not unobfervedly be taken off wrong.

BORDENTOWN, a pleafant town in Burlington co. New-Jerfey, is fituated at the mouth of Crofswicks Creek, on the E. bank of a great bend of Delaware River; 6 miles below Trenton, 9 N. E. from Burlington, by water, and 15 by land, and 24 miles N. E. from Philadelphia; and through this town, which contains about 100 houfes, a line of ftages paffes from New-York to Philadelphia. The fecond divifion of Heffians was placed in this town, in December, 1776; and by the road leading to it, 600 men of that nation efcaped, when Gen. Wafhington furprifed, and made prifoners of 886 privates, and 23 Heffian officers, at Trenton.—*Morse.*

BOSCAWEN, a townfhip in Hillfborough co. New-Hampfhire, on the weftern bank of Merrimack River above Concord; 43 miles N. W. of Exeter, and 38 S. E. of Dartmouth College; having 1108 inhabitants. Bofcawen Hills are in this neighborhood.—*ib.*

BOSCOVICH (Roger Jofeph), one of the moft eminent mathematicians and philofophers of the prefent age, was born, of virtuous and pious parents, on the 11th of May 1711, in the city of Ragufa, the capital

pital of a ſmall republic of the ſame name, lying on the eaſtern coaſt of the Adriatic Sea. At baptiſm, the name of Roger was given him, to which he added that of Joſeph when he received the ſacrament (A) of confirmation.

He ſtudied Latin grammar in the ſchools which were taught by the Jeſuits in his native city. Here it ſoon appeared that he was endued with ſuperior talents for the acquiſition of learning. He received knowledge with great facility, and retained it with equal firmneſs. None of his companions more readily perceived the meaning of any precept than he; none more juſtly applied general rules to the particular caſes contained under them. He announced his thoughts with great perſpicuity, and came ſoon to compoſe with propriety and elegance. His application was equal to his capacity, and his progreſs was rapid. At the beginning of the 15th year of his age, he had already gone through the grammar claſſes with applauſe, and had ſtudied rhetoric for ſome months. His moral behaviour had likewiſe been very good: he was reſpectful and obedient to his parents and maſters, affable and obliging to his equals, and exemplary in all the duties of religion. It was now time for him to determine what courſe he would ſteer through life; nor did he heſitate long in coming to a reſolution.

The Jeſuit fathers, by teaching the ſciences to youth, were very uſeful, and at the ſame time had a fine opportunity of obſerving their ſcholars and of drawing into their ſociety thoſe boys who ſeemed fit for their purpoſe. Such a ſubject as the young Boſcovich could not eſcape their attention. They ſhewed him particular kindneſs, to which he was not inſenſible. He had an ardent thirſt for learning; to advance in which he felt himſelf capable; and he thought he could nowhere have a better opportunity of gratifying this laudable inclination than in their order, in which ſo many perſons had ſhone in the republic of letters. Accordingly, with the conſent of his parents, he petitioned to be received among them; and his petition was immediately granted, becauſe it was deſired by thoſe to whom it was made.

It was a maxim with the Jeſuits to place their moſt eminent ſubjects at Rome, as it was of importance for them to make a good figure on that great theatre. Wherefore, as Roger's maſters had formed great expectations of him, they procured his being called to that city; whither he was ſent in the year 1725, and entered the noviceſhip with great alacrity. This noviceſhip was a ſpace of two years, in which the candidate made a trial of his new ſtate of life; and in the mean time his new ſuperiors obſerved him, and deliberated whether or not they would admit him into their body. During theſe two years, the novice was principally employed in exerciſes of piety, in ſtudying books of Chriſtian morality, and in becoming perfectly acquainted with the rules and conſtitutions of the order. After theſe two years were paſt, the Jeſuits were willing to retain Boſcovich, and he was no leſs deſirous of remaining with them. He therefore paſſed to the ſchool of rhetoric; in which, for two other years under the moſt expert maſters of the ſociety, young men perfected themſelves in the arts of writing and ſpeaking, which was of ſo great conſequence to perſons who were deſtined to treat ſo much with their neighbours. Here Boſcovich became perfectly well acquainted with all the claſſical authors, and applied with ſome predilection to Latin poetry.

After this he removed from the noviciate to the Roman College, in order to ſtudy philoſophy, which he did for three years. In order to underſtand the doctrine of phyſics, it was neceſſary to premiſe the knowledge of the elements of geometry, which is alſo otherwiſe proper for forming the mind, and for giving to it a true taſte for truth. Here it was that our young philoſopher came to be in his true element; and it now appeared how extremely fit his genius was for this kind of ſtudy. His maſter, though he was able and expert, inſtead of leading him on, was ſcarcely able to keep pace with him, and his condiſciples were left far behind. He likewiſe found the application of the mathematics to natural philoſophy pleaſant and eaſy. From all this, before the end of the three years, he had made a great advancement in phyſical and mathematical knowledge, and his great merit was generally acknowledged by his companions, and well known to his ſuperiors. He had already begun to give private leſſons on mathematics.

According to the ordinary courſe followed by the Jeſuits, their young men, after ſtudying philoſophy, were wont to be employed in teaching Latin and the belles lettres for the ſpace of five years, that ſo they might become ſtill better acquainted with polite learning, and arrive at the ſtudy of theology and the prieſthood at a riper age. But as Roger had diſcovered extraordinary talents for geometrical ſtudies, it was thought by his ſuperiors that it would be a pity to detain him from his favourite purſuits in a drudgery for which ſo many others were fit enough. He was therefore diſpenſed with from teaching thoſe ſchools, and was commanded to commence the ſtudy of divinity.

During the four years that he applied to that ſublime ſcience, he ſtill found ſome leiſure for geometry and phyſics; and even before that ſpace was ended, he was named profeſſor of his beloved mathematics.

He was now placed in an office for which he was ſuperlatively fit, and for which he had a particular predilection. Beſides having ſeen all the beſt modern productions on mathematical ſubjects, he ſtudied diligently the ancient geometricians, and from them learned that exact manner of reaſoning which is to be obſerved in all his works. Although he himſelf perceived eaſily the concatenation of mathematical truths, and could follow them into their moſt abſtruſe receſſes, yet he accommodated himſelf with a fatherly condeſcenſion to the weaker capacities of his ſcholars, and made every demonſtration clearly intelligible to them. When he perceived that any of his diſciples were capable of advancing faſter than the reſt, he himſelf would propoſe his

(A) For this article we are indebted to a dignified clergyman of the church of Rome, who was one of Boſcovich's favourite pupils.

his giving them private leffons, that fo they might not lofe their time; or he would propofe to them proper books with directions how to ftudy them by themfelves, being always ready to folve difficulties that might occur to them.

To the end that he might be the more ufeful to his fcholars, he took time from higher purfuits to compofe new elements of arithmetic, algebra, plain and folid geometry, and of plain and fpheric trigonometry; and although thefe fubjects had been well treated by a great many authors, yet Bofcovich's work will always be efteemed by good judges as a mafterly performance, well adapted to the purpofe for which it was intended. To this he afterwards added a new expofition of conic fections; in which, from one general definition, he draws, with admirable perfpicuity, all the properties of thofe three moft ufeful curves. He had meditated a complete body of pure and mixed mathematics, in which were to be comprehended treatifes on mufic, and on civil and military architecture; but from accomplifhing this he was prevented by other neceffary occupations.

According to the cuftom of fchools, every clafs in the Roman College, towards the end of the fcholaftic year, gave to the public fpecimens of their proficiency. With this view Bofcovich publifhed yearly a differtation on fome interefting phyfico-mathematical fubject. The doctrine of this differtation was defended publickly by fome of his fcholars, affifted by their mafter. At thefe literary differtations there was always a numerous concourfe of the moft learned men in Rome. His new opinions in philofophy were here rigoroufly examined and warmly controverted by perfons well verfed in phyfical ftudies: but he propofed nothing without folid grounds; he had forefeen all their objections, anfwered them victorioufly, and always came off with great applaufe and increafe of reputation. He publifhed likewife differtations on other occafions; and thefe works, though fmall in fize, are very valuable both for the matter they contain, and alfo for the manner in which it is treated. The principal fubjects of thefe differtations are the following: The fpots in the fun; the tranfit of mercury under the fun; the geometrical conftruction of fpheric trigonometry; the aurora borealis; a new ufe of the telefcope for the determination of celeftial objects; the figure of the earth; the arguments made ufe of by the ancients to prove the rotundity of the fame; the circles which are called ofculators; the motion of bodies projected in a fpace void of refiftance; the nature of infinites and of infinitely little quantities; the inequality of gravity in different parts of the earth; the annual aberration of the fixed ftars; the limits of the certainty to which aftronomical obfervations can arrive; a difcuffion on the whole of aftronomy; the motion of a body attracted by certain forces towards an immoveable centre in fpaces void of refiftance; a mechanical problem on the folid of greateft attraction; a new method of ufing the obfervation of the phafes in the lunar eclipfes; the cycloid; the logiftic and certain other curve lines; the forces that are called *living*; the comets; the flux and reflux of the fea; light; whirlwinds; a demonftration and illuftration of a paffage in Newton concerning the rainbow; the demonftration and illuftration of a method given by Euler regarding the calculation of fractions; the determination of the orbits of a planet by means of catoptrics, certain conditions of its motion being given; the centre of gravity and that of magnitude; the atmofphere of the moon; the law of continuity, and the confequences of it in the elements of matter and their forces; the law of the forces that exift in nature; lenfes and dioptrical telefcopes; the perturbation which appears to be caufed mutually by Jupiter and Saturn, and that chiefly about the time of their conjunction; the divifibility of matter and the elements of bodies; the objective micrometer;—befides other fubjects of the like nature, of which he has treated in feparate pieces, or in communications inferted in the tranfactions of literary focieties or academies, he being a member of thofe that are moft famous in Europe. It was in fome of the abovementioned differtations that Bofcovich made known firft to the world his fentiments concerning the nature of body, which he afterwards digefted into a regular theory, which is juftly become fo famous among the learned.

Father Noceti, another Jefuit, had compofed two excellent poems on the rainbow and the aurora borealis. Thefe poems were publifhed with learned annotations by Bofcovich; in which, among other things, he with great fagacity difcovers errors in optics into which De Dominis, Kepler, and others, had fallen.

His countryman, Benedict Stay, after having publifhed the philofophy of Defcartes in Latin verfe, attempted the fame with regard to the more modern and more true philofophy, and has executed it with wonderful fuccefs, to the admiration of all good judges. The two firft volumes of this elegant and accurate work were publifhed with annotations and fupplements by Bofcovich. Thefe fupplements are fo many fhort differtations on the moft important parts of phyfics and mathematics. Here is to be found a folution of the problem of the centre of ofcillation, to which Huygens had come by a wrong method; here he confutes Euler, who had imagined that the *vis inertiæ* was neceffary in matter; here he refutes the ingenious efforts of Riccati on the Leibnitzian opinion of the forces called *living*. He likewife fhews the falfehood of the mathematical prejudice, according to which the right line is confidered as effentially more fimple than curves, and makes it appear, that the notion of the faid right line is commonly accompanied with many paradoxes. He demonftrates, by the doctrine of combinations, fome beautiful theorems concerning the fpace occupied by the fmall maffes of body, with many ufeful obfervations on fpace and time.

Benedict XIV. who was a great encourager of learning, and a beneficent patron of learned men, was not ignorant how valuable a fubject Rome poffeffed in Bofcovich; and this pope gave him many proofs of the efteem he had for him. Two fiffures which had been perceived in the cupola of the church of St. Peter's on the Vatican had occafioned fome alarm. The pope defired Bofcovich and fome other mathematicians to make their obfervations and give their opinion on the fame. They obeyed, and their opinion was printed. They fhewed that there was no caufe to apprehend danger; but, for greater fecurity, they propofed certain precautions, which were adopted and put in execution.

The high opinion which the pope had formed of his talents, and the favour in which he was with Cardinal Valenti, Boſcovich. Valenti, miniſter of ſtate, proved hindrances to his going to America, for which a propoſal was made to him by the court of Liſbon. Some differences had long ſubſiſted between Spain and Portugal concerning the boundaries of their reſpective dominions in that great continent; and John V. of Portugal wiſhed that Boſcovich would go over and make a topographical ſurvey of the country in diſpute. He was not unwilling to undertake ſuch a taſk, which was entirely to his taſte; and he was reſolved at the ſame time to meaſure a degree of the meridian in Brazil, which might be compared with that meaſured at Quito by the French academicians Bouguer and Condamine, with the Spaniards Ulloa and Doy. But the pope hearing of this propoſal, ſignified to the Portugueſe miniſter at Rome, that his maſter muſt needs excuſe him for detaining Boſcovich in Italy, where he had occaſion for him, and could by no means conſent to part with him.

Accordingly a commiſſion was given to Boſcovich by Benedict to correct the maps of the papal eſtate, and to meaſure a degree of the meridian paſſing thro' the ſame. This he performed with great accuracy, aſſiſted by F. Chriſtopher Maire an Engliſh Jeſuit, and likewiſe a great mathematician. Their map was engraved at Rome, and is perhaps the moſt exact piece of the kind that ever was printed, as all the places are laid down from triangular obſervations made by the ableſt hands. Boſcovich alſo publiſhed, in a quarto volume in Latin, an account of the whole expedition, which appeared at Rome in the year 1755, and was afterwards printed at Paris in French in the year 1770. Here he gives a detail of their obſervations and of the methods they followed, and likewiſe of the difficulties they encountered, and how they were ſurmounted. One of theſe embarraſſed them a good deal at the time, but was afterwards matter of diverſion to them and others. Some of the inhabitants of the Apeninnes, ſeeing them paſs from hill to hill with poles and ſtrange machines, imagined that they were magicians come among their mountains in ſearch of hidden treaſures, of which they had ſome traditions: and as tempeſts of thunder and hail happened about the ſame time, they ſuppoſed that theſe calamities were cauſed by the forceries of their new viſitants. They therefore inſiſted that Boſcovich and Maire ſhould depart; and it was not eaſy to convince them that their operations were harmleſs. In this work there is inſerted a deſcription of the inſtruments made uſe of in determining the extent of the degree of the meridian; and the whole work may be extremely uſeful to practical geometricians and aſtronomers.

In the year 1757 the republic of Lucca entruſted Boſcovich with the management of an affair which was to them of conſiderable importance. Between that republic and the regency of Tuſcany there had ariſen a diſagreeable diſpute concerning the draining of a lake, and the direction to be given to ſome waters near the boundaries of the two eſtates. The Luccheſe ſenate choſe our philoſopher to treat of this buſineſs on their part. He repaired to the ſpot, conſidered it attentively, and drew up a writing, accompanied with a map, to ſhew more clearly what appeared to him moſt equitable and moſt advantageous for both parties. In order to enforce his reaſons the more effectually, it was thought proper that he ſhould go to Vienna, where the emperor Francis I. who was likewiſe grand duke of Tuſcany, reſided. He was ſo ſucceſsful in this negociation, that he obtained every thing that Lucca deſired, and at the ſame time acquired great eſteem at the imperial court. In proof of this, the empreſs queen made his opinion be aſked concerning the ſtability of the Ceſarean library, and the repairs to be made in it; which he gave in writing, and it was received with thanks, as being very well grounded. Boſcovich.

When he had concluded the affair which had brought him to Vienna, he foreſaw that, for a month or two, the ſnows in the Alps would not allow him to return to Italy. He therefore reſolved to employ that time in completing his ſyſtem of natural philoſophy, on which he had been meditating for the ſpace of thirteen years. He publiſhed his work on that great ſubject in the beginning of the year 1758, in the abovementioned city. We ſhall in the end give an account of that celebrated ſyſtem, and here go on with our narration.

On his return to Lucca, he not only met with the approbation of all he had done for the intereſt of the republic, but alſo the ſenate, in teſtimony of their gratitude, made him preſents, and inrolled him in the number of their nobility, which was the greateſt honour they had in their power to confer on him.

He, who was thus uſeful to foreigners, could not refuſe to be ſerviceable to his own country when an occaſion of being ſo offered itſelf. The Britiſh miniſtry had been informed, that ſhips of war, for the French, had been built and fitted out in the ſea-ports of Raguſa, and had ſignified their diſpleaſure on that account. This occaſioned uneaſineſs to the ſenate of Raguſa, as their ſubjects are very ſea-faring, and much employed in the carrying trade; and therefore it would have been inconvenient for them to have cauſed any diſguſt againſt them in the principal maritime power. Their countryman Boſcovich was deſired to go to London, in order to ſatisfy that court on the abovementioned head; and with this deſire he complied cheerfully on many accounts. His ſucceſs at London was equal to that at Vienna. He pleaded the cauſe of his countrymen effectually there, and that without giving any offence to the French, with whom Raguſa ſoon after entered into a treaty of commerce.

Boſcovich came to London the more willingly, as he was deſirous of converſing with the learned men of Britain. He was received by the preſident and principal members of the Royal Society with great reſpect; and to that great body he dedicated his poem on the eclipſes of the ſun and moon, which was printed on this occaſion at London, in the year 1760. This is one of his works on which he himſelf put the greateſt value, and it has been much eſteemed by the learned. An edition of it was publiſhed at Venice the year following, and a third at Paris, which is the moſt correct; a tranſlation of it into French has likewiſe been publiſhed at Paris. In this very elegant Latin poem he gives an exact compend of aſtronomy, which ſerves as an introduction to the ſubject; he then explains all that belongs to the doctrine of eclipſes, and their uſe in geography; he conſiders the phenomena that are obſerved in the eclipſes of the ſun, and likewiſe of the moon; he propoſes a theorem, which is his own, concerning the diſtribution of light refracted from the atmoſphere of the earth by the ſhadow of the moon, which happens in the lunar eclipfes; he explains the phenomenon of the reddifh colour which often appears in the moon when fhe is eclipfed, of which a fufficient explication had not before been given; this the author draws from the fundamental doctrine of Newton's theory concerning light and colours; and hence takes occafion to give a clear idea of the principal confequences of the faid theory. All this is clothed with a beautiful poetical drefs, and is adorned with pleafant epifodes, not to mention the learned annotations which are fubjoined. This poem was compofed, for the moft part, whilft the author was in journeys, or by way of amufement, when he was obliged to wait for the opportunities of making aftronomical obfervations.

The fellows of the Royal Society invited Bofcovich to accompany fome of their number to America, to obferve the tranfit of Venus, which was to happen in the year 1762; but being otherwife engaged, he could not accept of that invitation. He intended, however, by all means to obferve that remarkable phenomenon, and had fixed on Conftantinople as a proper place for doing fo. He was conducted thither in a Venetian man of war, and much honoured by one of the baylos of that republic, who commanded the veffel; but, to his great regret, they arrived too late. He returned, by land, in the company of the Englifh ambaffador; and a relation of that journey was publifhed in French and afterwards in Italian.

During thefe journeys, Bofcovich's place in the Roman College was well filled by fome of thofe whom he himfelf had trained up in mathematical learning. He was now called by the fenate of Milan to teach mathematics in the univerfity of Pavia, with the offer of a very confiderable falary. He and his fuperiors thought proper to accede to this propofal, and he was received without being fubjected to any previous examination; which was always obferved, excepting in fuch an extraordinary cafe, by the decrees of the univerfity. Here he taught, with great applaufe, for the fpace of fix years, having at the fame time the care of the obfervatory of the Royal College of Brera. About the year 1770, the emprefs queen made him profeffor of aftronomy and optics in the Palatine fchools of Milan; requiring of him, however, that he fhould continue to improve the obfervatory of Brera; which, under his direction, became one of the moft perfect in Europe.

Here he was extremely happy, teaching the fciences, applying to his favourite ftudies, and converfing and correfponding with men of learning and of polifhed manners; when an event happened which caufed to him the moft fenfible affliction. In the year 1773, the fociety to which he belonged, and to which he had been from his youth warmly attached, was, to his great regret and difappointment, abolifhed. They who had been Jefuits were allowed no longer to teach publicly; nor was there any exception made in favour of Bofcovich, neither (fuch was his humour then) would he have accepted of it, though it had been offered him. Propofals were made to him by feveral perfons of diftinction; and, after fome deliberation, he chofe Paris for his place of abode; to which he was induced by the circumftance of his being intimately acquainted with the prime minifter at that court. He had not been many months at Paris when the univerfity of Pifa fent him an invitation to go thither, in order to profefs aftronomy. But the French minifter, underftanding this, declared to the minifter of Tufcany, that it was the intention of his moft Chriftian majefty to make his dominions agreeable to Bofcovich, by giving him liberal appointments. In fact he was foon naturalized, and two large penfions were beftowed on him; the one as an honourable fupport, to the end that he might profecute his fublime ftudies at his eafe and in affluence; the other as a falary annexed to a new office, created in his favour, under the name of *Director of Optics for the Sea Service*, and with the fole obligation of perfecting the lenfes which are ufed in achromatical telefcopes.

At Paris he remained ten years, applying principally to optics, and much regarded, not only by the moft reafonable men of letters, but likewife by the princes and minifters, both of France and of other nations. But the greateft men are not exempt from being envied. Some of the French were difpleafed that a foreigner fhould appear fuperior to themfelves; others of them could not forget that Bofcovich had difcovered and expofed their miftakes. The irreligion which prevailed too much among thofe who bore the name of philofophers, was difagreeable to him. Thefe, and other fuch circumftances, made him wearied of Paris, and he defired to revifit his friends in Italy; for which purpofe he obtained leave of abfence for two years.

The firft place in Italy in which he made any ftay was at Baffano, a town in the territories of Venice. Here, mindful of his obligations, he printed what he had been preparing for the prefs during his ftay in France; and this compofes five volumes in large octavo, and is a treafure of optical and aftronomical knowledge. The fubjects treated of in thefe volumes are as follow: A new inftrument for determining the refracting and diverging forces of diaphonous bodies; a demonftration of the falfehood of the Newtonian analogy between light and found; the algebraic formulæ regarding the focufes of lenfes, and their applications for calculating the fphericity of thofe which are to be ufed in achromatical telefcopes; the corrections to be made in occular lenfes, and the error of the fphericity of certain glaffes; the caufes which hinder the exact union of the folar rays by means of the great burning glaffes, and the determination of the lofs arifing from it; the method of determining the different velocities of light paffing through different mediums by means of two dioptrical telefcopes, one common, the other of a new kind, containing water between the objective glafs and the place of the image; a new kind of objective micrometers; the defects and inutility of a dioptrical telefcope propofed and made at Paris, which gives two images of the fame object, the one direct, the other inverfe, with two contrary motions of moveable objects; maffes floating in the atmofphere, as hail of an extraordinary fize, feen on the fun with the telefcope, and refembling fpots; the aftronomical refractions, and various methods for determining them; various methods for determining the orbits of comets and of the new planet, with copious applications of thefe doctrines to other aftronomical fubjects, and ftill more generally to geometry and to the fcience of calculation; the errors, the rectifications, and the ufe of quadrants, of fextants, of aftronomical fectors, of the meridian line, of telefcopes called the inftruments of tranfits, of the meridian,

meridian, and of the parallactic machine; the trigonometrical differential formulæ, which are of ſo much uſe in aſtronomy; the uſe of the micrometrical rhombus, extended to whatever oblique poſition; the error ariſing from refractions in uſing the aſtronomical ring for a ſundial, and the correction to be made; the appearing and the diſappearing of Saturn's ring; the methods of determining the rotation of the ſun by means of the ſpots, propoſed formerly by the author, and now perfected; the greateſt exactneſs poſſible in determining the length of a pendulum oſcillating every ſecond of middle time by the compariſon of terreſtrial and celeſtial gravity; a compend of aſtronomy for the uſe of the marine, containing the elements of the heavenly motions, and of the aſtronomical inſtruments to be explained to a prince in the courſe of one month; a method for determining the altitude of the poles with the greateſt exactneſs, by means of a gnomon alone, where other inſtruments are not to be had; the determination of the illuminated edge of the moon to be obſerved on the meridian; a method of uſing the retrograde return of Venus to the ſame longitude, for determining the leſs certain elements of her orbit; a method for correcting the elements of a comet, of which the longitude of the node is given, and the inclination of the orbit has been found nearly; another method for the ſame purpoſe, and for finding the elliptical orbit, when the parabolic one does not agree with the obſervations; a method for correcting the elements of a planet by three obſervations; the projection of an orbit inclined in the plane of the ecliptic; the projection of an orbit inclined in any other plane; the calculation of the aberration of the ſtars, ariſing from the ſucceſſive propagation of light; ſome beautiful theorems belonging to triangles, which are of great uſe in aſtronomy, reduced to moſt ſimple demonſtrations.

After having ſeen the impreſſion of theſe five volumes finiſhed, Boſcovich left Baſſano, made an excurſion to Rome, and viſited his old friends there and in other places of Italy. He then took up his abode at Milan, and applied to the reviſing of ſome of his old works, and to the compoſing of new ones. He ſet himſelf particularly to prepare annotations and ſupplements to the remaining two volumes of Stay's Modern Philoſophy, which he had not had time to publiſh ſooner, and which he lived not to publiſh.

He was happy at Milan in the neighbourhood of Brera, where was his favourite obſervatory; and in the company of many friends, who were become the more dear to him by his long abſence from them. But he began to conſider, with grief, that his two years of abſence were drawing to an end. He was very unwilling to leave Italy and return to France. He thought of applying for a prolongation of his abſence; he thought of making intereſt at the Imperial court for ſome honourable commiſſion, which might be a pretext to him for remaining at Milan; but he was afraid that the propoſal of never returning to France might appear indelicate and ungrateful to a nation from which he was receiving conſiderable penſions. He apprehended that thoſe perſons at Paris who had before oppoſed him, would take occaſion to tax him with ingratitude, and that hence his reputation would be tarniſhed. Theſe, and other ſuch thoughts, occaſioned a great perplexity of mind, which was followed by a deep melancholy; and this could not be alleviated by the advice and comfort of his friends, becauſe by degrees he became incapable of hearing reaſon, his ideas being quite confuſed, and his imagination diſordered. To this diſagreeable change the ſtate of his health perhaps contributed. A gout had been wandering for ſome time through his body, and he had caught a ſevere cold; nor would he admit of medical aſſiſtance, of which he had always been very diffident. It may alſo be that his long and intenſe application had hurt the organs of the brain, which in ſome manner are ſubſervient to the uſe of reaſon as long as the ſoul is united to the body. Be that as it will, during the laſt five months of his life this great man, who had been ſo far ſuperior in reaſoning to his ordinary fellow creatures, was much inferior to every one of them who is endued with the right uſe of the underſtanding. He had indeed ſome lucid intervals, and once there were hopes of a recovery; but he ſoon relapſed, and an impoſthume breaking in his breaſt, put an end to his mortal exiſtence. He died at Milan on the 13th of February 1787, in the 76th year of his age.

He was tall in ſtature, of a robuſt conſtitution, of a pale complexion. His countenance was rather long, and was expreſſive of cheerfulneſs and good humour. He was open, ſincere, communicative, and benevolent. His friends ſometimes regretted that he appeared to be too irritable, and too ſenſible of what might ſeem an affront or neglect, which gave himſelf unneceſſary uneaſineſs. He was always unſtained in his morals, obedient to his ſuperiors, and exact in the performance of all Chriſtian duties, as became a Catholic prieſt, and in the obſervance of the particular rules of his order. His great knowledge of the works of nature made him entertain the higheſt admiration of the power and wiſdom of their Creator. He ſaw the neceſſity and advantages of a divine revelation, and was ſincerely attached to the Chriſtian religion, having a ſovereign contempt of the preſumption and fooliſh pride of unbelievers; and being fully perſuaded that we cannot make a more noble uſe of our underſtanding than by ſubjecting it humbly to the authority of the Supreme Being, who knows numberleſs truths far beyond the utmoſt limits of our narrow comprehenſion, and who may juſtly require our belief of any of them that he ſees fit to propoſe to us.

The death of our philoſopher, who truly deſerved that name, was heard with regret by the learned through Europe, and more than ordinary reſpect has been paid to his memory. At Raguſa funeral exequies were performed for him with great ſolemnity by order of the ſenate, who aſſiſted at them in a body; on which occaſion an eloquent oration in praiſe of him was pronounced. By a decree of the ſame ſenate, a Latin inſcription to his honour, engraved on marble, was placed in the principal church of their city. Of this inſcription the following is a copy:

This infcription was compofed by his friend and countryman the celebrated poet Benedict Stay. Zamagna, another of his countrymen, who had likewife been his fellow jefuit, publifhed a panegyric on him in elegant Latin. A fhort encomium of him is to be found in the *Eftratto della Literatura Europea;* and another, in form of a Letter, was directed by M. de la Lande to the Parifian journalifts, and by them given to the public. A more full eulogium has been written by M. Fabroni; and another is to be met with in the journal of Modena; a third was publifhed at Milan by the Abbate Ricca; and a fourth at Naples by the Dr Julius Bajamonti, of which a fecond edition was made in the year 1790. Of this laft chiefly ufe has been made here.

But what muft fecure to Bofcovich the efteem of pofterity are his works, of the greater part of which we have already taken notice. We have mentioned, 1. His Elements of Mathematics, with his Treatife on Conic Sections; 2. His many Differtations publifhed during his profefforfhip in the Roman college; 3. His account of his Survey of the Pope's Eftate; 4. His Theory of Natural Philofophy; 5. His Poem on the Eclipfes; 6. His five volumes printed at Baffano.

To thefe we may add his hydrodynamical pieces. He had made a particular ftudy of the force of running water, and of its effects in rivers; and he was often confulted concerning the beft means to prevent rivers from corroding their banks, and from overflowing the neighbouring plains, which often happens in Italy, where the Alps and Apennines pour down fo many impetuous ftreams. He gave a writing on the damages done by the Tiber at Porto Felice; another on the project of turning

turning the navigation to Rome from Fiumicino to Maccareſe; a third on two torrents in the territory of Perugia; a fourth on the bulwarks on the river Panaro; a fifth on the river Sidone, in the territory of Placentia; a ſixth on the entrance into the ſea of the Adige. He wrote other ſuch works on the bulwarks of the Po; on the harbours of Ancona, of Rimini, of Magna Vacca, and Savona, beſides others, almoſt all which were printed. He had likewiſe received a commiſſion from Clement XIII. to viſit the Pomptin lakes, on the draining of which he drew up his opinion in writing, to which he added further elucidations at the deſire of Pius VI. On theſe occaſions he ſhowed how uſeful philoſophy may be to the public; and of this he gave another proof when it was referred entirely to his judgment to determine whether or not the cupola of the cathedral of Milan could bear the weight of a very high ſpire, which it was propoſed to raiſe on it, and which was actually erected according to his directions.

His application to obſtruſe ſtudies did not hinder him from paying ſome attention to what is more pleaſant. We have ſeen that he was a poet: he was alſo well acquainted with hiſtory, and particularly with that of the Greeks and Romans, and with their antiquities. He wrote a diſſertation on an ancient villa diſcovered in his time upon the Tuſculan Hill, and on an ancient dial found there, which diſſertation was publiſhed at Rome in a literary journal. He wrote likewiſe three letters on the obeliſk of Cæſar Auguſtus, two of which were printed with his own name, and the third under the name of another.

Beſides all theſe works that were given to the public in his lifetime, many writings of his remained in manuſcript in the hands of different perſons, and particularly with his friend M. Gaetani, and many more with Count Michael de Sorgo, a Raguſan ſenator, who inherited all his papers that were in his own hands at his death. Theſe, it is hoped, have either been already ſent to the preſs or will be ſo; as nothing came from the pen of Boſcovich which was not uſeful and deſerving to ſee the light.

It now remains that we give an account of his Theory of Natural Philosophy; and in doing this we ſhall, in the *firſt* place, lay before our readers a view of this ſyſtem. We ſhall, in the *ſecond* place, relate, from what principles and by what ſteps it was deduced. We ſhall, *thirdly*, take notice of the principal objections made to it, and ſubjoin the author's anſwers to the ſame. We ſhall, *finally*, ſhew how happily it may be applied to explain the general properties of matter, as well as the particular qualities of all the claſſes of bodies, which have been examined according to what it teaches.

I View of Boſcovich's ſyſtem of natural philoſophy.

1. In this ſyſtem, therefore, the whole maſs of matter, of which all the bodies of the univerſe are compoſed, conſiſts of an exceeding great, yet ſtill finite, number of ſimple, indiviſible, inextended, atoms. Theſe atoms are endued with *repulſive* and *attractive* forces, which vary and change from the one to the other, according to the diſtance between them, in the following manner: In the leaſt and innermoſt diſtances they repel one another; and this repulſive force increaſes beyond all limits as the diſtances are diminiſhed, and is conſequently ſufficient for extinguiſhing the greateſt velocity, and for preventing the contact of the atoms. In the ſenſible diſtances, this force is *attractive*, and decreaſes, at leaſt ſenſibly, as the ſquares of the diſtances increaſe, conſtituting univerſal gravity, and extending beyond the ſphere of the moſt diſtant comets. Between this innermoſt repulſive force and the outermoſt attractive one, in the inſenſible diſtances, many varieties and changes of the force, or determination to motion, take place: for the repulſive force decreaſes as the diſtance increaſes. At a certain diſtance it comes to vaniſh entirely; and, when that diſtance is increaſed, attraction begins, increaſes, becomes leſs, vaniſhes; and the diſtance becoming greater, the force becomes repulſive, increaſes, leſſens, and vaniſhes as before. Many varieties and changes of this kind happen in the inſenſible diſtances, ſometimes more rapidly, ſometimes more ſlowly, and ſometimes one of the forces may come to nothing, and then return back to the ſame without paſſing to the other. For all this there is full room in the diſtances that are inſenſible to us, ſeeing the leaſt part of ſpace is diviſible *in infinitum*. Beſides theſe repulſive and attractive forces, our atoms have that *vis inertiæ* which is admitted by almoſt all modern philoſophers. Theſe atoms, endued with theſe forces, conſtitute the whole ſubſtance of Boſcovich's ſyſtem; which, however ſimple and ſhort it may appear to be, has numberleſs and very wonderful conſequences, as we ſhall ſee afterwards. But, that a more clear idea of the whole theory may be eaſily formed, we ſhall make uſe of a geometrical figure well accommodated to that purpoſe. The right line C′AC is an axis, from which, in the point A, is drawn the right line AB at right angles. AB is conſidered as an *aſymptote*; on each ſide of which the two curves, quite ſimilar and equal, DEFGHIKLMNOPQRSTVU on the one ſide, and D′E′F′G′ on the other, are placed. Now, if ED be ſuppoſed to be *aſymptotical*, and be extended, it will ſtill approach to BA, but will never come to touch it. This curve ED approaches to the axis C′C, comes to it in E, cuts it and departs to a certain diſtance in F, after which it again approaches the ſame axis and cuts it in G. In like manner it forms the arches GHI, IKL, LMN, NOP, PQL. At laſt it goes on in T*psV*, which is aſymptotical, and approaches to the axis; ſo that the diſtances from it are in a duplicate reciprocal proportion of the diſtances from the right line BA. If from any points of the axis, as from *a*, *b*, *d*, we raiſe the perpendiculars *a g*, *b r*, *d h*, the ſegments of the axis A *a*, A *b*, A *d*, are called *abſciſſes*, and repreſent the diſtances of any two points of matter from one another; and the perpendiculars *a g*, *b r*, *d h*, are called *ordinates*, and exhibit the repulſive or attractive force, according as it lies on the ſame ſide with D, or on the other ſide of the axis.

5 The whole theory expreſſed by a geometrical curve. Plate VI. fig. 6.

Now it is evident that, in this form of the curve line, the *ordinate a g* will be increaſed beyond whatever limits, if the abſciſs A *a* be leſſened likewiſe beyond whatever limits; that if this abſciſs be increaſed to A *b*, the *ordinate* will be leſſened, and will paſs into *b r*, which will ſtill be leſſened as it approaches from *b* to E, where it will come to nothing; that then, the axis being increaſed to A *d*, the *ordinate* will change its direction into *b h*, and, on the oppoſite ſide, will increaſe at firſt to to F, then it will decreaſe through *i l* as far as G, where it will again vaniſh, and again change its direction in *m n* to the former, and that, in the ſame manner, it will vaniſh and change its directions in all the ſections I, L, N, P, R, until the *ordinates o p, v s*, become of a conſtant direction, and decreaſe, at leaſt ſenſibly, in a reciprocal duplicate propoition of the abſciſſes A *o*, A *v*. Wherefore, it is manifeſt, that by ſuch a curve are expreſſed our forces; at firſt *repulſive*, and increaſing beyond all limits, the diſtances being leſſened in like manner, and which decreaſe, the ſame diſtances being augmented; then vaniſh, change their direction, and become *attractive;* vaniſh again, and become *repulſive;* till at laſt, at ſenſible diſtances, they remain on the ſide oppoſite to D, and are *attractive* in a duplicate reciprocal proportion of the diſtances.

We may alſo obſerve, that the *ordinates* may increaſe or decreaſe rapidly, as in *y v, z t*, or ſlowly, as in *v x, z c;* and, conſequently, that the forces may increaſe or decreaſe in like manner. We may add, that the curve may return back without interſecting, or even touching, the axis, as in *f*, and may return after having touched the ſame axis.

Although this curve expreſſes very clearly the *repulſive* and *attractive* forces of our ſyſtem, yet, at firſt ſight, it may appear to be a complicated irregular line. But the author ſhews that his curve is uniform and regular, and may be expreſſed by one uniform algebraical equation; which it will be neceſſary for us to conſider, in order to give ſatisfaction to our readers, and to do juſtice to the theory.

3 The ſimplicity of this curve proved.

Wherefore, from what we have ſeen, the curve muſt have the following ſix conditions: *1ſt*, It muſt be regular and ſimple, and not compoſed of an aggregate of arches of different curves. *2dly*, It is neceſſary that it cut the axis C′AC in certain given points only, at two equal diſtances on each ſide AE′, AE, AG′, AG, and ſo on. *3dly*, That to every *abſciſs* an *ordinate* correſpond. *4thly*, That if we take equal *abſciſſes* on each ſide of A, they have equal *ordinates*. *5thly*, That the right line AB be an *aſymptote*, the area BAED being aſymptotical, and conſequently infinite. *6thly*, That the arches terminated by any two interſections may be varied at pleaſure, and recede to any diſtance from the axis C′AC, and approach at pleaſure to whatever arches of whatever curves, cutting them, touching them, or oſculating them, in any place and manner.

In order to find an algebraical formula expreſſing the nature of a curve line that would anſwer all theſe ſix conditions, let us call the ordinate *y*, the abſciſs *x*, and let it be made $xx=z$. Then let us take the values of all the abſciſſes AE, AG, AI, &c. with the negative ſign, and let the ſum of the ſquares of all theſe values be called *a*, the ſum of the products of every two ſquares *b*, the ſum of the products of every three, *c*, and ſo on; and let the product of all of them be called *f*, and the number of the ſame values *m*. All this being ſuppoſed, let it be made $z^m + a z^{m-1} + b z^{m-2} + c z^{m-3}$ &c. $+ f = \text{P}$. If we ſuppoſe P equal to nothing, it is clear that all the roots of that equation will be real and poſitive; that is, the ſquares only of the quantities AE, AG, AI, &c. which will be the values of *z;* and therefore, as it is $x = \pm\sqrt{z}$, becauſe it is $xx = z$, it is likewiſe clear that the values of *x* will be both AE, AG, AI, poſitive, and A′E′, A′G′, &c. negative.

This being done, let any quantity be multiplied by *z*, providing it hath no common diviſor with P, leſt *z* vaniſhing, it likewiſe might vaniſh; and having made *x* an infiniteſim of the firſt order, it may become an infiniteſim of the ſame, or of a lower order, as will be whatever formula $z^r + g z^{r-1} + h z^{r-2}$ &c. $+ l;$ which, being ſuppoſed equal to *o*, may have as many imaginary, and as many and whatever real roots, providing none of them be thoſe of AG, AE, AI, &c. either poſitive or negative. If then the whole formula be multiplied by *z*, let this product be called Q.

If we make $\text{P}-\text{Q}\,f = o$, this equation will ſatisfy the five firſt conditions above mentioned; and the value of Q being properly determined, the ſixth condition alſo may be complied with.

For, in the firſt place, ſeeing the value P and Q are made equal to *o*, they have no common root, and therefore no common diviſor. Hence this equation cannot be reduced to two by diviſion; and therefore it is not compoſed of two equations, but is ſimple, and therefore exhibits one ſimple continued curve, which is not compoſed of any others; which is the firſt condition.

Secondly, The curve thus expreſſed will cut the axis C′AC in all the points E′, G, I, &c. G′, &c. and in them only: for it will cut that axis only in thoſe points in which $y = o$, and in all of them. Moreover, where it will be $y = o$, it will alſo be $\text{Q}\,y = o;$ and therefore, becauſe of $\text{P}-\text{Q}\,y = o$, it will be $\text{P} = o$. But this will happen only in thoſe points in which *z* will be one of the roots of the equation $\text{P} = o;$ that is, as we have ſeen above, in the points E, G, I, or E′, G, &c.: wherefore, only in thoſe points will *y* vaniſh, and the curve cut the axis. Again, that the ſame curve will cut it in all theſe points, is clear from this, that in them all it will be $\text{P} = o$. Wherefore it will likewiſe be $\text{Q}\,y = o;$ but it will not be $\text{Q} = o$, ſeeing there is no common root of the equations $\text{P} = o$ and $\text{Q} = o:$ it muſt therefore be $y = o$, and the curve will cut the axis: and thus the ſecond condition is ſatisfied.

Beſides, whereas it is $\text{P}-\text{Q}\,x = o$, it will be $y = \frac{\text{P}}{\text{Q}}$: the abſciſs *x* being, however, determined, we will have a certain determinate quantity for *z;* and thus P, Q, will be determined, and the only two of the kind. Wherefore *y* alſo will be ſole and determined; and therefore to every abſciſs *z*, one only ordinate *y* will correſpond. This is the third condition.

Again, whether *x* be aſſumed poſitive or negative, providing it be of the ſame length, ſtill the value $z = xx$ will be the ſame, and therefore the values of both P and Q will be the ſame: wherefore *y* will ſtill be the ſame. Taking, therefore, equal abſciſſes *z* on both ſides of A, the one poſitive, the other negative, they will have equal correſponding ordinates. This is the fourth condition.

If *x* be leſſened beyond all limits, whether it be poſitive or negative, *z* likewiſe will be leſſened beyond all limits, and will become an infiniteſim of the ſecond order: wherefore, in the value P, all the terms will decreaſe *in infinitum*, except in *y*, becauſe all the reſt beſides it are multiplied by *z;* and thus the value P will be as yet finite. But the value Q, which has the formula

Boscovich's System of Natural Philosophy.

mula multiplied by z, will be lessened *in infinitum*, and will be an infinitesim of the second order: therefore $\frac{P}{Q} = y$ will be augmented *in infinitum*, so as to become an infinite of the second order. Wherefore the curve will have the right line AB for an *asymptote*, and the area BAED will increase *in infinitum*: and if the ordinate y be assumed positive on the side AB, and express repulsive forces, the asymptotic arch ED will lie on the same side AB. This is the fifth condition.

Now the value Q can be varied in infinite manners; so that still the conditions for which it was assumed may be fulfilled; and therefore the arches of the curve intercepted by the intersections may be varied in infinite manners; so that the first five conditions of the curve may be implemented: whence it follows, that they may be so varied that the sixth condition may also be answered.

For if there be given, however many, and whatever arches of whatever curve, providing they be such that they recede always from the asymptote AB, and thus no right line parallel to that asymptote cut these arches in more than one point, and in them let there be taken as many points as you please, and as near one another; it will be easy to assume such a value of P, that the curve shall pass through all these points, and the same may be varied infinitely; so that still the curve will pass through all the same points.

Let the number of points assumed be what you please $= r$, and, from every one of such points, let right lines be drawn parallel to AB, as far as the axis C'AC, which must be the ordinates of the curve that is sought; and let the abscisses from A to the said ordinates be called M^1, M^2, M^3, &c. and the ordinates $'N^1$, $'N^2$, $'N^3$, &c. Let there now be taken a certain quantity $Az^r + Bz^{r-1} + Cz^{r-2} + Gz$, and let this quantity be supposed equal to R. Then let another such quantity T be assumed, so that z vanishing, whatsoever term of it may vanish, and so that there be no common divisor of the value of P, and of the value of R+T; which may be easily done, seeing all the divisors of the quantity P are known. Let it now be made $Q = R + T$, and then the equation of the curve will be $P - Ry - Ty = o$. After this, let there be put in the equation M1, M2, M3, successively for x, and N1, N2, N3, &c. for y; we will have a number of equations equal to r, which will contain the values of A, B, C. . . . . G, each of them of one dimension, in number likewise equal to r; and, besides, we will have the given values of M1, M2, &c. N1, N2, N3, &c. and the arbitrary values which in T are the coefficients of z.

By these equations, which are in number r, it will be easy to determine the values A, B, C, ... G, which are likewise in number r, assuming the first equation, according to the usual method, the value A, and substituting it in all the following equations; by which means the equations will become $r-1$. These, again, by throwing out the value B, will be reduced to $r-2$, and so on until we come to one only; in which the value Q being determined by means of it, going back, all the preceding values will be determined, one by each equation.

The values A, B, C, ... G, being in this manner determined, in the equation $P - Ry - Ty = o$, or $P - Qy = o$, it is clear that, the values M1, M2, M3, &c. being successively put for x, the values of the ordinate y must successively be N1, N2, N3, &c. and, therefore, that the curve must pass through these given points in those given curves; and still the value Q will have all the preceding conditions. For z being lessened beyond whatever limits, every one of its terms will be lessened beyond whatever limits, seeing all the terms of the value of T are lessened which were thus assumed, and likewise the terms of the value R are lessened, which are all multiplied by z; and, besides this, there will be no common divisor of the quantities P and Q, seeing there is none of the quantity P and R+T.

But if two of the nearest of the points assumed in the arches of the curves, on the same side of the axis, be supposed to accede to one another beyond whatever limits, and at last to coincide, which will be done by making two M equal, and likewise two N equal; then the curve sought will touch the arch of the given curve; and if three such points coincide, they will *osculate* it: nay, as many points as we please may be made to meet together where we please; and thus we may have *osculations* of what order we please, and as near one another as we please, the arch of the given curve approaching as we please, and at whatever distances we please, to whatever arches of whatever curves, and yet still preserving all the six conditions required for expressing the law of the repulsive and attractive forces. And whereas the value of T can be varied in infinite manners, the same may be done in an infinite number of ways; and therefore a simple curve, answering the given conditions, may be found out in an infinite number of ways. *Q. E. F.*

What we have said will, we hope, satisfy our readers, and especially those of them who are in the least acquainted with high geometry, that Boscovich's curve is simple, regular, and uniform; and that therefore the law of repulsive and attractive forces, expressed by it, is simple and regular.

II. If this system were a mere hypothesis, it would still be very ingenious, and, from what we shall say afterwards, would still be well adapted for explaining the phenomena of nature. But its author is far from looking upon it as an arbitrary supposition; he assures us that he was led to it by a chain of strict reasoning, from evident principles. We shall now give an abridgement of that reasoning from his Dissertations on the Law of *Continuity*, and from his Theory of Natural Philosophy.

4 Proofs of the theory.

He tells us, then, that in the examination of Leibnitz's opinion of the *vires vivæ*, he came to consider the collision of bodies, and took for example two equal bodies, A proceeding with six degrees of velocity, and B following with the velocity of 12: after the collision, they proceed jointly with the common velocity 9. Now, in the moment of collision, it either happens that A passes abruptly from the velocity 6 to the velocity 9, without passing through the velocity 7 and 8, and B passes from 12 of velocity to 9, without passing through 11 and 10; or else there must be some cause which accelerates the one and retards the other before they come to contact. In the first case, the law of continuity is broken; in the second, immediate contact of bodies would be rejected. Maclaurin saw this difficulty, and mentioned it in his work on *Newton's Discoveries*, l. 1. c. 4. He, not having courage to recede from the common opinion, allowed a breach, in such cases, of the law of continuity; but Boscovich maintains

Boscovich's System of Natural Philosophy. maintains the universality of the law of continuity; and holds, that no bodies touch one another really and mathematically, but only physically and sensibly to us.

5
The law of continuity proved. *The law of continuity is that by which variable quantities, passing from one magnitude to another, pass through all the intermediate magnitudes, without ever abruptly passing over any of them.* This law Boscovich proves to be universal, in the first place, from induction. Thus we see that the distances of two bodies can never be changed without their passing through all the intermediate distances. We see the planets move with different velocities and directions; but in this they still observe the law of continuity. In heavy bodies projected, the velocity decreases and increases through all the intermediate velocities; the same happens with regard to elasticity and magnetism. No body becomes more or less dense without passing through the intermediate densities. The light of the day increases in the morning and decreases at night through all the intermediate possible degrees. In a word, if we go through all nature, we shall see the law of continuity strictly take place, if all things be rightly considered. It is true, we sometimes make abrupt passages in our minds; as when we compare the length of one day with that of another immediately following, and say that the second is two or three minutes longer or shorter than the former, passing all at once, in our way of speaking, round the globe; but if we take all the longitudes, we shall find days of all the intermediate lengths. We likewise sometimes confound a quick motion with an instantaneous one: thus, we are apt to imagine that the ball is thrown abruptly out of the gun; but, in truth, some space of time is required for the gradual inflammation of the powder, for the rarefaction of the air, and for the communication of motion to the ball. In like manner, all the objections made against the law of continuity may be solved to satisfaction.

6
A breach of this law impossible. But however strong this argument from judgment may appear to be, yet Boscovich goes farther, and maintains, that a breach of this law, in the proper cases, is metaphysically impossible. This argument he draws from the very nature of continuity. It is essential to continuity that, where one part of the thing *continued* ends and another part begins, the limit be common to both. Thus, when a geometrical line is divided into two, an indivisible point is the common limit of both: thus time is *continued*; and therefore where one hour ends, another immediately begins, and the common limit is an indivisible instant. Now, as all variations in variable quantities are made in time, they all partake of its continuity; and hence none of them can hasten by an abrupt passage from one magnitude to another, without passing through the intermediate magnitudes. As we cannot pass from the sixth hour to the ninth without passing through the seventh, and eighth; because, if we did, there would be a common limit between the sixth hour and the ninth, which is impossible; so likewise you cannot go from the distance 6 to the distance 9 without passing through the distances 7 and 8; because, if you did, in the instant of passage you would be both at the distance 6 and at the distance 9, which is impossible. In like manner, a body that is condensed or rarefied cannot pass from the density 6 to the density 9, or *vice versa*, without passing through the densities 7 and 8; because, in the abrupt passage, there would be two densities, 6 and 9, in the same instant. The body must pass through all the intermediate densities. This it may do quickly or slowly, but still it must evidently pass through them all. The like may be said of all variable quantities; and thence we may conclude, that the law of continuity is universal.

7
Objections to this law answered. But, in creation, is there not an instance of an abrupt passage from *non-existence* to *existence*? No, there is not; because before existence a *being* is nothing, and therefore incapable of any state. In creation, a *being* does not pass from one state to another abruptly; it passes over no intermediate state: it begins to exist and to have a state, and existence is not divisible. Do we not, at least, allow of an abrupt passage from repulsive to attractive forces in our very theory itself? We do not. Our repulsive forces diminish, through all the intermediate magnitudes, down to nothing; through which, as a limit, they pass to attraction. In the building of a house or ship, neither of them is augmented abruptly; because the additions made to them are effected solely by a change of distances between the parts of which they are composed; and all the intermediate distances are gone through. The like may be said of many other such cases; and still the law of continuity remains firm and constant.

8
Impossibility of contact between bodies. Let us now apply this doctrine to the case above mentioned of the collision of two bodies. We say that the body B cannot pass from the velocity 6 to the velocity 9 without passing through the velocities 7 and 8; because if it did, in the moment of contact of the two superficies it would have the velocities 6 and 9. Now a body cannot have two velocities at the same instant. For if it had two *actual* velocities at the same time, it would be in two different places at the same time: if it had two different *potential* velocities or determinations to a certain velocity, it would be capable of being, after a given time, in two places at once—both which are impossible. It is therefore necessary that it go through the velocities 7 and 8, and through all the parts of them. What we have said of the bodies A and B may be said universally of all bodies. Therefore no two bodies in motion can come to immediate contact; but their velocities must undergo the successive necessary change before contact. And as the velocity to be extinguished may be increased beyond all limits, an adequate cause to effect this extinction must be admitted.

9
Repulsive forces. This naturally leads us to the interior repulsive forces of our system. For the cause retarding the one body and accelerating the other must be a *force*, because by this we mean a determination to motion; and it must be repulsive, because it acts *from* the body; and it must increase beyond all limits, seeing the velocity of the incurring bodies may be increased beyond all limits. It must likewise be mutual, because action and reaction are always equal, as may be proved by induction.

10
Inextended atoms. From these repulsive forces Boscovich deduces the inextension of his atoms: for this repulsion being common to all matter, must cause a perfect simplicity in the first elements of body. If these elements were extended, and consequently compounded of particles of an inferior order, these particles might possibly be separated, and then they might meet, and an abrupt passage from one velocity to another might take place, which we have excluded from nature by induction, and by a positive argument.

Besides

Beſides this, by rejecting the extenſion of the firſt elements of matter, we get rid at once of all the difficulties ariſing from continued extenſion in body, which have always perplexed the philoſophers, and have never been ſatisfactorily explained. If theſe elements of matter are extended, each of them may be divided *in infinitum*, and each part may ſtill be divided *in infinitum*. Can this diviſion be actually made by the power of God or not? Can there be one *infinite* in number greater than another? Can there be a *compound* without a *ſimple* of the ſame kind? Theſe difficulties regard not ſpace, which is no real being; but they would regard matter if it had continued extenſion. All theſe perplexities are removed by maintaining, as Boſcovich does, that the firſt elements of bodies are perfectly ſimple, and therefore inextended (A).

11 Attractive forces.

With regard to the exterior attractive forces of our ſyſtem, there can be no queſtion; ſeeing they conſtitute univerſal gravity, the effects of which we ſee and feel every day. But between the interior repulſive and exterior attractive forces we muſt admit many tranſitions from repulſion to attraction, and from attraction back to repulſion, in inſenſible diſtances, which are indicated to us by coheſion, fermentation, evaporation, and other phenomena of nature. And thus we have given, in ſhort, Boſcovich's proofs of his whole ſyſtem.

12 Objections to the ſyſtem anſwered.

III. This ſyſtem has been well received by the learned in Europe, and has contributed much to render its author famous; yet many objections againſt it have been propoſed. Some are ſtartled at the rejection of all immediate contact between bodies; and indeed Boſcovich is perhaps the firſt of mankind who advanced that opinion; but he allows that bodies approach ſo near to one another, as to leave no ſenſible diſtance between them: and his repulſive forces make the ſame impreſſion on the nerves of our ſenſes as the ſolid bodies could do. And therefore this opinion of his, however new, is nowiſe contrary to the teſtimony of our ſenſes. He only removes a prejudice which was before univerſal.

Some ſay, that they cannot even form an idea of an inextended atom, and that Boſcovich reduces all matter to nothing: but certainly extenſion is not neceſſary for the eſſence of a *being*, as muſt be allowed by all thoſe who hold that ſpirits are inextended. Becauſe all the bodies that fall under our ſenſes are extended, we are apt to look upon extenſion as eſſential to matter: but this error may be corrected by reflection, and an idea of an inextended atom may be formed, by conſidering the nature of a mathematical point, which is the limit of any two contiguous parts of a line.

Others again have ſaid, that if the elements of matter were void of extenſion, there would be no difference between body and ſpirit. But the difference between body and ſpirit does not conſiſt in the having or not having extenſion; but in this, that the atoms of matter are endued with repulſive and attractive forces, which ſpirit has not; and ſpirit has a capacity of thought and volition which bodies have not.

We may here obſerve, that among the ancients Zeno, and among the moderns Leibnitz, held, that the firſt principles of matter are inextended points. But both held this opinion with the inconſiſtency, that they maintained the continued extenſion of bodies, without ever being able to ſhew how continued extenſion could ariſe from inextended elements.

It has been objected likewiſe, that our repulſive and attractive forces are no better than the occult qualities of the Peripatetics. The like objection has been made to Newton's attraction: but the anſwer is eaſy. We obſerve the effects, and take notice of them; for them we muſt admit an adequate cauſe, without being able to determine, whether that cauſe is an immediate law of the Creator, or ſome mediate inſtrument that he makes uſe of for that purpoſe.

Some are unwilling to give up the idea of motion occaſioned by immediate impulſe: but can they ſhow a good reaſon why *ſome diſtance* may not occaſion motion as well as *no diſtance?* Theſe are the principal objections that have been made againſt the Boſcovichian ſyſtem.

IV. Before we proceed to the explication of phenomena by means of our theory, we muſt advert, that in the curve expreſſing this theory, the abſciſſes denote the diſtances between the atoms that are under conſideration; the ordinates give the preſent *force*, and the area between any two of theſe ordinates gives the ſquare of the velocity generated between them: the arches are either repulſive or attractive, according as they fall upon the ſame ſide with the aſymptotic curve EG, or on the oppoſite ſide. 13 Obſervations with regard to the curve.

We muſt, in the next place, conſider the paſſages from one ſide of the axis to the other. Sometimes the paſſage is from repulſion to attraction, at other times from attraction to repulſion. The firſt are called *limits of coheſion*, becauſe a particle removed from that limit returns back to it; becauſe if it is removed to a greater diſtance it is attracted back, and if it is removed nearer it is repelled back. The ſecond are called *limits of noncoheſion;* becauſe a particle removed thence to a greater diſtance is repelled ſtill further, and if removed nearer it is attracted ſtill nearer. Of the firſt kind are E, I, N; of the ſecond are G, L. Likewiſe, when the curve touches the axis, it may either be an attractive part of the curve, or a repulſive part. Theſe limits may be nearer one another, or farther away; and the limits of coheſion may be ſtronger or weaker, according as the forces near them are greater or leſs. 14 Limits of coheſion, &c.

Boſcovich conſiders minutely the effects of theſe varieties of limits and forces; firſt with regard to two points, then with regard to three and four, demonſtrating

(A) If a particle of matter is not extended, in what reſpect does it differ from a point of ſpace? Says Boſcovich, it is endowed with attractive and repulſive forces. What is this *it* before it is thus endowed? Does it *then* differ from a point of ſpace? We can form no notion of any ſuch difference. But a point of ſpace, conſidered as an individual, is diſtinguiſhed from another individual only by its ſituation; it is therefore immoveable, but matter is moveable. Have theſe forces, then, which make matter an object of ſenſe, any ſubſtratum, any thing in which they are inherent as qualities? What are the things which theſe qualities diſtinguiſh from each other as individuals?

Boſcovich's Syſtem of Natural Philoſophy.

ing the great variety of forces that may ariſe from theſe various combinations, and ſhewing how from ſimple atoms a great variety of bodies may be formed. He particularly proves, that, from the various poſition of the atoms, they may either always repel or always attract other atoms, or do neither. Four atoms may form a pyramid, eight may form a cube, and ſo on, in regular or irregular figures. Particles of the loweſt order may compoſe particles of a ſecond order, theſe of a third, and ſo on. This he exemplifies by a library, in which the letters of the books ſhould be compoſed of ſmall points, placed ſo near one another as that their diſtance could not be perceived without the help of a microſcope. Here the letters will be compoſed of points, the words of letters, and all the variety of books on different ſubjects, and in different languages, would be compoſed of words. In like manner, he ſays, his atoms may compoſe particles, theſe may compoſe others of different orders, of which may be formed various bodies, animal, vegetable, air, fire, water, earth, whole planets, central bodies, the whole univerſe.

15 Compoſition of bodies.

16 The ſyſtem applied, to account for

But to be more particular, our author proceeds to apply his ſyſtem to mechanics, and demonſtrates, with his uſual accuracy and originality, what regards the centre of gravity, action and reaction, the colliſion of bodies, the centre of equilibrium, and of oſcillation.

Of theſe ſubjects he treats in the ſecond part of his *Theoria;* to which we muſt refer our learned readers, as it cannot be eaſily abridged.

In the third part of the ſame work he proceeds to account for the general properties of matter, beginning with *impenetrability*. This naturally flows from the interior repulſive forces, which prevent the compenetration of any two points. Beſides, as the leaſt part of ſpace is diviſible *in infinitum*, it is infinitely improbable that any two points ſhould ever meet, ſeeing they have an infinite number of other lines in which they can move, beſides the one that would join them. But an apparent compenetration might take place, if one body ſhould meet another with ſo great a velocity as not to give time to the repulſive forces to exert their action. Thus an iron ball may paſs ſwiftly near a ſtrong magnet, without being ſenſibly attracted by it, which it would be if it moved more ſlowly. Thus a ball from a gun paſſes through a piece of wood ſo quickly as to make only a paſſage for itſelf, without breaking the neighbouring parts, which it would do were its motion more ſlow. Of this kind of compenetration we have a reſemblance in *light* paſſing through pellucid bodies.

17 Impenetrability,

18 Coheſion,

Coheſion has never been well accounted for by any philoſopher before Boſcovich. From his ſyſtem it follows naturally, as we have ſeen in ſpeaking of the limits of coheſion; for when two atoms are placed in a limit of that kind, they neceſſarily cohere more or leſs ſtrongly, according as that limit is ſtronger or weaker. From the coheſion of the atoms ariſes the coheſion of compounded particles, and conſequently of ſenſible bodies.

19 Extenſion,

From the coheſion of particles ariſes the extenſion of bodies; becauſe there muſt always be ſpace between the particles. However, it is evident that this extenſion is not formed of a continuity of matter; though it may appear to be ſo to our ſenſes, which cannot perceive the ſmall intermediate diſtance between the parts of ſome bodies, and much leſs the diſtances between the ſimple elements of which they are compoſed.

Boſcovich's Syſtem of Natural Philoſophy.

20 Figure,

Extenſion of bodies involves *figurability;* becauſe every extended body muſt be ſurrounded by ſome ſuperficies of a certain figure; but the ſuperficies of bodies can never be accurately determined, upon account of the inequalities in all ſurfaces. We take however, that figure for the true one which the body appears to come neareſt. Thus we call the earth a globe, notwithſtanding the hills and valleys that are on it.

Under the ſame figure, and of the ſame magnitude, there may be contained very different quantities of matter. Hence we come to the conſideration of *denſity*. That body is moſt denſe which contains in the ſame ſpace the greateſt number of atoms, and *vice verſa*.

21 Denſity,

This denſity may be increaſed beyond any given limits by the nearer approach of the atoms to one another. Hence a body of any given magnitude, however ſmall, may come to be diviſible beyond any given limits.

22 Mobility,

Mobility, which is likewiſe reckoned among the general properties of body, is eſſential to our ſyſtem, ſeeing an eſſential part of it conſiſts in *forces*, which are determinations to motion, at leaſt in certain diſtances.

23 Gravity,

Univerſal gravity in ſenſible diſtances is likewiſe a branch of our theory. On which ſubject it may be obſerved, that perhaps our curve, after it has extended beyond the ſphere of the comets moſt diſtant from the ſun, may depart from its aſymptotical nature, and approach to the axis, interſect it, and paſs to repulſion. This would effectually anſwer the objection made by ſome againſt Newton's attraction, when they allege, that, from his opinion, it would follow, that the fixed ſtars, and all matter, would be drawn together into one maſs. If ſuch a repulſion takes place, it may ſoon paſs again into attraction, and form limits of coheſion; ſo that our ſun may be in ſuch a limit with regard to the fixed ſtars, and our planetary ſyſtem make only a ſmall part of the whole univerſe. And this may ſuffice concerning the general properties of matter.

24 Fluidity,

Let us now deſcend to ſome particular claſſes of bodies, of which ſome are fluid, others ſolid. The parts of fluid bodies are eaſily ſeparated, and eaſily moved round one another, becauſe they are ſpherical and very homogeneous; and hence their forces are directed more to their centres than to one another, and their motions through one another are leſs obſtructed. Between the particles of ſome of them there is very little attraction, as in fine ſand or ſmall grains of ſeed, which approach much to fluidity. The particles of ſome others of them attract one another ſenſibly, as do thoſe of water, and ſtill more thoſe of mercury. This variety ariſes from the various combinations of the particles themſelves, of which we have already taken notice. But in air the particles repel one another very ſtrongly; and hence comes that great rarefaction, when it is not compreſſed by an external force. Its particles muſt be placed in ample limits of repulſion.

25 Solidity,

Solid bodies are formed of parallelopipeds, fibres, and of irregular figures. This occaſions a greater coheſion than in fluids, and prevents the motion of the parts round one another; ſo that when one part is moved all the reſt follow. Of theſe bodies ſome are harder, whoſe particles are placed in limits which have ſtrong repul-

ſive

Bofcovich's Syftem of Natural Philofophy.

five arches within them; others are fofter, whofe particles have thofe arches of repulfion weaker. Some are flexible, the particles of which are placed in limits that have weak arches of repulfion and attraction on each fide; and if thofe arches are fhort, the particles may come to new limits of cohefion, and remain bent: but if the arches are longer, the former repulfion and attraction will continue to act, and bring back the body to its former pofition; nay, in doing this with an accelerated velocity, the parts will pafs their former limits, and vibrate backwards and forwards, as may be feen in a bended fpring. Thus elafticity is accounted for.

26 Softnefs, flexibility, and elafticity.

27 Vifcofity.

Vifcous bodies ftand in the middle between folid and fluid. Their particles have lefs cohefion than the firft, and more than the fecond: they ftick to other bodies by an attraction which their particles have from their compofition. In like manner water itfelf fticks to fome bodies, and is repelled by others. All which arifes from the different compofition of the particles, which gives a variety of refpective forces.

28 Organization.

What appears very wonderful in nature, is the compofition of organic bodies. But if we confider that particles may be fo formed, that they may repel fome and attract others, the whole of vegetation, nutrition, and fecretion, may be underftood, and follows from our fyftem. And as one particle may attract another in one part only, and repel it in every other fituation, hence may be gathered the orderly fituation of the particles in many cryftallizations. The great variety of repulfive and attractive forces, or limits of cohefion, of the pofition of atoms, and of combinations of particles, will account for all thefe phenomena.

29 Chemical operations.

The chemical operations, which are fo curious in themfelves, and fo ufeful to fociety, are well explained by Bofcovich's fyftem, and ferve as a confirmation of its truth. Of this we fhall give fome inftances. When fome folids are thrown into fome liquids, there happens to be a greater attraction between the particles of the folid and of the liquid than there is between the particles of the folid itfelf. Hence the particles of the folid are detached and furrounded by the fluid; this mixture retaining the form of globules, and therefore continuing to be fluid. This is called *folution*. But when the folid particles are covered to a certain depth, the attractive forces ceafe on account of the different diftances, and no more of the folid is detached. Then the fluid is faid to be *faturated*. If into this mixture another folid be put, the particles of which attract the fluid more ftrongly, and perhaps at greater diftances than the particles of the former; then the fluid will abandon the former and cleave to the latter, diffolving them, and the particles of the former will fall to the bottom in the form of powder, into which they had been reduced by the folution. This feparation is called *precipitation*. Perhaps rain arifes from a precipitation of this kind, when the aqueous particles are left by the air, which is more ftrongly attracted by fome other particles floating in the atmofphere.

Fluids of the fame fpecific gravity are eafily mixed; and even though the fpecific gravity be different, the particles of the one attract thofe of the other, in fuch a manner that they feem to form one fluid by a kind of folution. Nay, it happens, that two fluids mixed together form a folid, becaufe their particles come to be in the limits of cohefion. They may even occupy lefs fpace than they did before, by being attracted into lefs diftances between their parts.

Fermentation is a neceffary confequence of our fyftem. For when bodies, whofe particles, by the variety of their compofition, are endued with different forces, come to be mixed, there muft arife an agitation of the parts, and an ofcillation among them; fometimes greater, fometimes lefs, according to the nature of the particles. This agitation is ftopped by the expulfion of fome particles, by the intrufion of others into vacant fpaces and by the impreffion of external bodies; but always there is a change in what remains, becaufe there is a new difpofition of particles.

30 Fire and fufion, &c.

Fire confifts in a violent fermentation of fulphureous matter, efpecially when it meets with the matter of light in any quantity. This fermentation agitates ftrongly the parts of other bodies, feparates them from one another, and often throws them into a ftate of fufion; the cohefion between their parts being broken, and they being thrown into a circular motion. In this ftate they may be often mixed together, fo as to form one body; they may be again feparated by the action of the fame fire, which evaporates fome of them fooner, fome later. Hence the art of fmelting metals.

When, in the agitation occafioned by fire, fome of the particles are thrown out into an arch of repulfion, they may fly off and evaporate. Sometimes the whole body may be thrown into a ftrong repulfion and volatilization, or a fudden explofion take place; when, before the particles are near an equilibrium, a fmall force may occafion a great change; as the foot of a bird may occafion the fall of a great rock, which was before almoft detached from a mountain. In evaporation, the bodies that remain affume a particular figure, as all falts do; and this upon account of their particles having certain parts only that attract one another, and confequently occafion a particular difpofition. All thefe chemical operations evidently prove that there are in nature repulfive and attractive forces between the particles of bodies at fmall diftances; which greatly confirms our whole fyftem.

31 Light.

Bofcovich holds, that light is an *effluvium*, emitted with great velocity from the luminous bodies by a ftrong repulfion. He explains all the moft remarkable properties of this extraordinary matter according to his own principles, and that with great acutenefs. On this fubject it is obfervable, that Newton faw the neceffity of admitting repulfive forces for the reflexion of light, which extend at fome diftance from the reflecting furface, and therefore refemble the repulfive forces of our theory.

32 Electricity and magnetifm.

Our author gives likewife a probable explication of electricity, according to Franklin's ingenious hypothefis, and likewife of magnetifm, deducing the whole of the appearances from various attractions and repulfions. He fuppofes that fire and the electrical fluid differ only in this, that fire is in actual fermentation, and not fo the electrical fluid.

33 Senfation.

Finally, he explains our bodily fenfations, in which he agrees pretty much with other philofophers; excepting in this, that what they attribute to the immediate contact of bodies, or of certain particles emitted from them, he afcribes to attractions and repulfions; which indeed

Boſcovich's Syſtem of Natural Philoſophy.

indeed are particularly fit for cauſing that motion in our nerves, which is ſuppoſed to take place in the organs of ſenſation, and to be thence communicated to the brain.

It is to be obſerved, that although Boſcovich maintains, that the very firſt elements of matter are void of extenſion; yet he allows, that of theſe elements, combined in a certain manner, may be formed extended particles of various figures, the parts of which may be ſo coherent as to be inſeparable by any power in nature. By theſe means the opinion of thoſe philoſophers who are ſo fond of extended particles, may be in ſo far gratified. Nay, the Peripatetics may, if they pleaſe, adopt Boſcovich's inextended atoms for their *Materia Prima* without any inconſiſtency; and his repulſive and attractive forces may ſerve for their *ſubſtantial forms*. And as God can make impreſſions on our ſenſes independently of the atoms, their abſolute accidents may in ſome ſenſe be admitted. Nor would ſome ſuch extraordinary exertions of Divine Power favour idealiſm in the ordinary courſe of nature.

34 Reconciliation of this with other ſyſtems,

But what is of more conſequence, it is more than probable, that had Newton lived to be acquainted with the Boſcovichian theory, he would have paid to it a very great regard. This we may conjecture from what he ſays in his laſt queſtion of optics; where, after having mentioned thoſe things which might be explained by an attractive force, ſucceeded by a repulſive one on a change of the diſtances, he adds, "And if all theſe things are ſo, then all nature will be very ſimple, and conſiſtent with itſelf, effecting all the great motions of the heavenly bodies by the attraction of gravity, which is mutual between all thoſe bodies, and almoſt all the leſs motions of its particles by another certain attractive and repulſive force, which is mutual between thoſe particles." And a little after, treating of the elementary particles, he ſays: "Now it ſeems that theſe elementary particles not only have in themſelves the *vis inertiæ*, and thoſe paſſive laws of motion which neceſſarily ariſe from that force, but that they likewiſe perpetually receive a motion from certain active principles: ſuch as gravity, and the cauſe of fermentation, and of the coheſion of bodies. And I conſider theſe principles, not as occult qualities, which are feigned to flow from the ſpecific forms of things, but as univerſal laws of nature, by which the things themſelves were formed. For that truly ſuch principles exiſt, the phenomena of nature ſhew, although what may be their cauſes has not as yet been explained. To affirm that every ſpecies of things is endued with ſpecific occult qualities, by which they have a certain power, is indeed to ſay nothing; but to deduce two or three general principles of motion from the phenomena of nature, and then to explain how the properties and action of all corporeal things follow from thoſe principles, this truly would be to have made a great advancement in philoſophy, although the cauſes of thoſe principles were not as yet known. Wherefore I do not heſitate to maintain the above ſaid principles of motion, ſeeing they extend widely through all nature." From this paſſage we may ſafely conclude, that the great Britiſh philoſopher would have been highly pleaſed, had he ſeen all nature ſo well explained by the one ſimple law of forces propoſed by the Raguſan.

35 Eſpecially that of Newton.

36 Compariſon of this ſyſtem to the key of a cypher.

Boſcovich himſelf was ſo fully convinced of the truth of his ſyſtem, that he was wont to make uſe of the following compariſon: When a letter has been written in occult characters, and we are endeavouring to decypher it, we make various ſuppoſitions of alphabets; and when we have found one according to which the whole letter comes to have a reaſonable meaning, agreeable to all the circumſtances of time, place, perſons, and things, we can entertain no doubt of our having diſcovered the true key of the cypher—ſo, ſaid he, my ſyſtem explains ſo well all the phenomena to which it has been properly applied, that I muſt flatter myſelf that I have diſcovered the true key of nature.

37 Exiſtence of God.

The being accuſtomed to contemplate ſo deeply the univerſe and the materials of which it is compoſed, made Boſcovich ſee moſt clearly the evident neceſſity of admitting an all powerful, intelligent, ſelf-exiſtent Being, for the creation of thoſe materials, and for the arrangement of them into their preſent beautiful form. He was at a loſs to find words ſtrong enough to expreſs his ſurpriſe, that there ſhould be any man, not to ſay any one pretending to the name of philoſopher, who could be ſo deaf as not to hear the voice of nature loudly proclaiming its Author from all, even the leaſt of its parts. He gives us his ſentiments on this, the moſt important of all ſubjects, in the appendix to his *Theoria*, in which he treats of God and of the ſoul of man.

38 The world cannot be the effect of chance;

There, in the firſt place, he ſhows the abſurdity of their opinion, who maintain that this world may have been the work of *chance*, the effect of a jumble of ſelf-exiſtent, ſelf-moving atoms: becauſe chance is an empty word without a real meaning. Whatever exiſts has its determinate cauſe, and can only be called *fortuitous* by us on account of our ignorance of that cauſe. Beſides this, though the number of atoms compoſing this world is finite, yet their poſſible combinations are many times *infinitely infinite*: for they may be placed in infinite places of an infinite line; of theſe lines there is an infinite number in every *plane*, and of theſe planes there is an infinite number in ſpace. Again, theſe points may have an infinite number of velocities in an infinite number of directions. From all this it is evident, that the combinations in which the points of matter may be, is infinite in a high degree, whereas *duration* can be infinite in only one dimenſion. Hence it is infinitely improbable that ever the preſent combination of things could come out by chance. And this is ſo much the more infinitely improbable, becauſe the diſorderly, chaotic combinations are infinitely more than the regular ones. The whole of matter might roll about in a blind motion for a boundleſs eternity, without ever being capable to produce one ſingle muſhroom.

Moreover, had matter been in motion from all eternity, every atom would have deſcribed an infinite line, and then a part of that line would be aſſignable at an infinite diſtance from the point of ſpace in which the atom is at preſent: but an infinite line can never be run over; therefore the atom could never have come to its preſent place; and therefore the ſuppoſition is abſurd. Nothing ſucceſſive can be eternal with a *paſt* eternity, though it can continue without end. God alone can be eternal and actually infinite, but his eternity and infinity are beyond our comprehenſion.

39 Nor have exiſted from eternity.

Neither can the world have exiſted of itſelf in any thing like to its preſent form from all eternity; for matter is perfectly indifferent to numberleſs ſtates, and to

Boscovich's System of Natural Philosophy.

to its present state it must be determined. This present state is perfectly incapable of determining itself, because this determination must be previous to its existence. It must be determined by the preceding state, which is also incapable of determining itself, and for its determination we must have recourse to the state before. Thus, though we go back to eternity, we shall still find a nullity of determination: now an infinite sum of *nothing* is *nothing*; and therefore as the present state of things could have no determination, it could not possibly exist.

It is therefore evident that there must be a Determiner extrinsic to the material world. This Determiner must have an infinite knowledge of all the possible combinations, and an infinite elective creative power to chuse and create freely the combination he pleased, in that point of eternity that he chose, with all the numberless circumstances that are agreeable to him.

40 Attributes of God which appear in the creation.

And here what a vast field of contemplation is laid open to a philosophic mind! What a truly infinite knowledge was requisite to foresee so many ends, and so many means requisite for obtaining those ends, as are contained in the creation! Let us consider light, for example, which was to be emitted for so many ages from so many luminous bodies, with so great velocity, so as to penetrate so many mediums with different degrees of reflectibility and refrangibility, with so many other wonderful qualities; at the same time so many bodies were to be perfectly fitted for reflecting this light in a certain manner, and the animal eye was to be so formed as to have a picture of visible objects painted on the bottom of it.—How many particular combinations were necessary for all this? What shall we say of the so many herbs, flowers, trees, and animal bodies as there are on this our earth? All their kinds and species, all the series of their individuals, all their parts and particles, were foreseen, intended, and contrived, by one act of the Divine Mind. Again, how wonderful are the heavenly bodies, of what surprising magnitude, moving in the most beautiful order, at an immense distance from one another? To say nothing of the numberless creatures that are beyond the reach of the best telescope, or below that of the microscope. He who reflects ever so little on these things, must necessarily see the most evident proofs of an infinite power, wisdom, and providence; and he must be filled with admiration and awful respect for the Creator and Ruler of the universe.

41 Natural religion.

Nor are we unconcerned spectators of this grand scene. God has been pleased to make us enter deeply into his great plan of creation. He singled us out among an infinite number of possible human beings, in order to call us into existence at a fixed period; and he has made a vast number of his creatures contribute to the formation of these wonderful machines, our bodies, as likewise to our nourishment, to our preservation, to our necessities, conveniences, and gratifications. Every moment that we exist we are enjoying a great number of benefits, expressly designed for us by that Supreme Being. This evidently demands from us the highest degree of gratitude, love, and obedience.

42 Revelation.

Let us go a step still farther: Is it not very reasonable to suppose, that our God, who affords us so many instances of his beneficence towards us in the natural order, will also, out of compassion to our weakness and ignorance, have favoured us with a more full and explicit manifestation of himself, of our duties towards him, and of his intentions concerning us? According to Boscovich and all true philosophers, reason itself alone, and true philosophy, point out to us the probability at least of God's having given us a still better and surer guide, by whose direction we may attain to that perfect happiness which we naturally thirst after, and to which we must have been designed by our Maker. This is probable from reason alone; and of this great fact we are ascertained by unquestionable authority.

Boshmen ‖ Boston.

BOSHMEN have been generally described as a distinct race of Hottentots, who are enemies to the pastoral life, (see *Boshies-Men*, Encycl.) This M. Vaillant affirms to be a mistake; and we think he has completely proved that it is so. "These infamous wretches (says he) do not form a particular nation, nor are they a people who have had their origin in the places where they are now found. *Boshmen* is a name composed of two Dutch words, which signify *bush-men*, or *men of the woods*; and it is under this appellation that the inhabitants of the Cape, and all the Dutch in general, whether in Africa or America, distinguish those malefactors or assassins who desert from the colonies, in order to escape punishment. In a word, they are what in the British and French West India islands are called *Maroon Negroes*. These Boshmen, therefore, far from being a distinct species, are only a promiscuous assemblage of mulattoes, negroes, and mastizos, of every species, and sometimes of Hottentots and basters (see Baster, *Supplement*), who all differing in colour, resemble each other in nothing but in villany. They are land pirates, who live without laws and without discipline, abandoned to the utmost misery and despair; base deserters, who have no other resources but plundering and crimes. They retire to the steepest rocks and the most inaccessible caverns, and there they pass their lives. From these elevated places they command an extensive prospect over the surrounding plains, lie in wait for the unwary traveller and the scattered flocks, pour down upon them with the velocity of an arrow, and suddenly falling upon the inhabitants and their cattle, slaughter them without distinction. Loaded with booty, and whatever they can carry with them, they then repair to their gloomy caves, which they never quit till, like the lions, hunger again impels them to fresh massacres. But as treachery always marches with a trembling step, and as the presence of one resolute person is sufficient to overawe whole troops of these banditti, they carefully shun those plantations where they are certain that the owners themselves reside. Artifice and cunning, the usual resources of timid souls, are the only means which they employ, and the only guides that accompany them in their expeditions."—*Vaillant's Travels into the Interior Parts of Africa.*

BOSTON, (Encyclopædia.) The following more accurate description is from Dr Morse's Gazetteer.

Boston, The capital of the state of Massachusetts, the largest town in New England, and the third in size and rank in the United States, lies in 42. 23. 15. N. lat. and 70. 58. 53. W. long. This town, with the towns of Hingham, Chelsea and Hull, constitute the county of Suffolk; 176 miles S. W. of Wiscasset, 61 S. by W. of Portsmouth, 164 N. E. of New-Haven, 252 N. E. of New-York, 347 N. E. of Philadelphia, and 500 N. E. of the city of Washington. Boston

Boston. ton is built upon a peninfula of irregular form at the bottom of Maffachufetts Bay, and is joined to the main land by an ifthmus on the fouth end of the town leading to Roxbury. It is two miles long but is of unequal breadth: the broadeft part is 726 yards. The peninfula contains about 700 acres (other accounts fay 1000) on which are 2376 dwelling houfes. The number of inhabitants in 1790 was 18,038, but the increafe has been very confiderable fince. The town is interfected by 97 ftreets, 36 lanes, and 26 alleys, befides 18 courts, &c. moft of thefe are irregular, and not very convenient. State-ftreet, Common-ftreet, and a few others, are exceptions to this general character; the former is very fpacious, and being on a line with Long Wharf, where ftrangers ufually land, exhibits a flattering idea of the town.

Here are nineteen edifices for public worfhip, of which nine are for Congregationalifts, three for Epifcopalians, and two for Baptifts; the Friends, Roman Catholics, Methodifts, Sandemanians and Univerfalifts have one each. Moft of thefe are ornamented with beautiful fpires, with clocks and bells. The other public buildings are the State-Houfe, Court-Houfe, two Theatres, Concert Hall, Faneuil Hall, Gaol, an Alms-Houfe, a Work-Houfe, a Bridewell and Powder Magazine. Franklin Place, adjoining Federal-ftreet Theatre, is a great ornament to the town; it contains a monument of Dr. Franklin from whom it takes its name, and is encompaffed on two fides with buildings, which, in point of elegance, are not exceeded, perhaps, in the United States. Here are kept in capacious rooms, given and fitted up for the purpofe, the Bofton Library, and the valuable Collections of the Hiftorical Society. Moft of the public buildings are handfome, and fome of them are elegant. A magnificent State-Houfe is now erecting in Bofton, on the S. fide of Beacon Hill, fronting the Mall, the corner-ftone of which was laid with great formality and parade on the 4th of July, 1795; and which over-tops the monument on Beacon Hill.

The Market Place, in which Faneuil Hall is fituated, is fupplied with all kinds of provifions which the country affords. The fifh market in particular, by the bounteous fupplies of the ocean and rivers, not only furnifhes the rich with the rareft productions, but often provides the poor with a cheap and grateful repaft.

Bofton Harbor, is formed by Point Alderton on the S. and by Nahant Point on the N. The harbor is capacious enough for 500 veffels to ride at anchor in good depth of water; whilft the entrance is fo narrow as fcarcely to admit two fhips abreaft. It is variegated with about forty iflands, of which fifteen only can be properly called fo; the others being fmall rocks or banks of fand, flightly covered with verdure. Thefe iflands afford excellent pafturage, hay and grain, and furnifh agreeable places of refort in fummer to parties of pleafure. Caftle Ifland is about three miles from the town; its fortifications, formerly called Caftle William, defend the entrance of the harbor. It is garrifoned by about fifty foldiers, who ferve as a guard for the convicts, who are fent here to hard labour. The convicts are chiefly employed in making nails.

The Light-Houfe ftands on a fmall ifland on the N. entrance of the channel, (Point Alderton and Nantafket Heights being on the S.) and is about 65 feet high. Bofton. To fteer for it from Cape Cod, the courfe is W. N. W. when within one league of the Cape; from Cape Cod to the Light-Houfe is about 16 leagues; from Cape Ann the courfe is S. W. diftant 10 leagues. A cannon is lodged and mounted at the Light Houfe to anfwer fignals.

Only feven of the iflands in the bay are within the jurifdiction of the town, and taxed with it, viz. Noddle's, Hog, Long, Deer, Spectacle, Governor's and Apple Iflands.

The wharves and quays in Bofton are about eighty in number, and very convenient for veffels. Long Wharf, or Bofton Pier, in particular, extends from the bottom of State-ftreet 1743 feet into the harbor in a ftraight line. The breadth is 104 feet. At the end are 17 feet of water at ebb tide. Adjoining to this wharf on the north is a convenient wharf called Minot's T, from the name of its former proprietor and its form. Veffels are fupplied here with frefh water from a well furrounded by falt water, which has been dug at a great expenfe. Long Wharf is covered on the north fide with large and commodious ftores, and in every refpect exceeds any thing of the kind in the United States. In February, 1796, a company was incorporated to cut a canal between this harbor and Roxbury, which is nearly completed.

The view of the town, as it is approached from the fea, is truly beautiful and picturefque. It lies in a circular and pleafingly irregular form round the harbour, and is ornamented with fpires, above which the monument of Beacon Hill rifes pre eminent; on its top is a gilt eagle bearing the arms of the Union, and on the bafe of the column are infcriptions, commemorating fome of the moft remarkable events of the late war. Beacon Hill is the higheft ground on the peninfula, and affords a moft delightful and extenfive profpect. The common below it contains about 45 acres always open to refrefhing breezes; on its eaft fide is the Mall, a very pleafant walk above 500 yards in length, adorned with rows of trees, to which an addition of about 100 yards has been lately added. Charles River and Weft Bofton bridges are highly ufeful and ornamental to Bofton; and both are on Charles River, which mingles its waters with thofe of Myftic River, in Bofton harbor. Charles River bridge connects Bofton with Charleftown in Middlefex county, and is 1503 feet long, 42 feet broad, ftands on 75 piers, and coft the fubfcribers 50,000 dollars. It was opened June 19, 1787.

	Feet long.
Weft Bofton bridge ftands on 180 piers, is	3483
Bridge over the gore, 14 piers,	275
Abutment Bofton fide,	$87\frac{1}{2}$
Caufeway,	3344
Diftance from the end of the Caufeway to Cambridge meeting-houfe,	7810
Width of the Bridge,	40

This beautiful bridge exceeds the other as much in elegance as in length, and coft the fubfcribers 76,700 dollars. Both bridges have draws for the admiffion of veffels, and lamps for the benefit of evening paffengers.

Seven Free Schools are fupported here at the public expenfe, in which the children of every clafs of citizens may freely affociate together. The number of fcholars

Boston. ſcholars is computed at about 900, of which 160 are taught Latin, &c. There are beſides theſe many private ſchools.

The principal ſocieties in the Commonwealth hold their meetings in this town, and are, the Marine Society, American Academy of Arts and Sciences, Maſſachuſetts Agricultural Society, Maſſachuſetts Charitable Society, Boſton Epiſcopal Charitable Society, Maſſachuſetts Hiſtorical Society, Society for propagating the Goſpel, Maſſachuſetts Congregational Society, Medical Society, Humane Society, Boſton Library Society, Boſton Mechanic Aſſociation, Society for the aid of Immigrants, Charitable Fire Society, and ſeven reſpectable Lodges of free and accepted Maſons.

The foreign and domeſtic trade of Boſton is very conſiderable, to ſupport which there are three Banks, viz. the Branch of the United States Bank, the Union, and the Maſſachuſetts Bank; the latter conſiſts of 800 ſhares of 500 dollars, equal to 400,000; the capital of the Union Bank is, 1,200,000 dollars, 400,000 of which is the property of the State. In 1748, 500 veſſels cleared out of this port for, and 430 were entered from, foreign parts. In 1784, the entries of foreign and coaſting veſſels were 372, and the clearances 450. In 1794, the entries from foreign ports were 567. In 1795, theſe entries amounted to 725, of which the ſhips were 96, barques 3, ſnows 9, polacre 1, brigs 185, dogger 1, ſchooners 362, ſhallop 1, and ſloops 65. The principal manufactures conſiſt of rum, loaf-ſugar, beer, ſail-cloth, cordage, wool and cotton cards, playing cards, pot and pearl aſhes, paper hangings, hats, plate, glaſs, tobacco, and chocolate. There are thirty diſtilleries, two breweries, eight ſugar houſes, and eleven ropewalks.

Eight years ago, the intercourſe with the country barely required two ſtages and twelve horſes, on the great road between this and New-Haven, diſtant 164 miles; whereas there are now twenty carriages and one hundred horſes employed. The number of the different ſtages that run through the week from this town is upwards of 20, eight years ago there were only three.

Attempts have been made to change the government of the town from its preſent form to that of a city; but this meaſure, not according with the democratic ſpirit of the people, has as yet failed. At an annual meeting in March, nine Selectmen are choſen for the government of the town; at the ſame time are choſen a Town Clerk, a Treaſurer, 12 Overſeers of the Poor, twenty-four Firewards, twelve Clerks of the Market, twelve Scavengers, twelve Conſtables, beſides a number of other officers. If the inhabitants do not reap all the advantages they have a right to expect from their numerous officers, it is not for want of wholeſome laws for the regulation of the weights, meaſures and quality of proviſions, or other branches of police, but, *becauſe the laws are not put in execution.*

Beſides thoſe called Trained Bands, there are four other military companies in Boſton, viz. the Ancient and Honourable Artillery Company, the Cadets, Fuſiliers and Artillery Company. The Ancient and Honourable Artillery Company was incorporated in 1638, and the election of a captain and officers of it for the year is on the firſt Monday in June annually, which is obſerved here as a day of feſtivity. Several officers in the American army, who ſignalized themſelves in the late war, received their firſt knowledge of tactics in this military ſchool.

Boſton || Boſwell.

Boſton was ſettled as early as 1631, from Charleſtown; it was called Shaumut by the Indians; Trimountain by the ſettlers in Charleſtown, from the view of its three hills; and had its preſent name in token of reſpect to the Rev. Mr Cotton, a miniſter of Boſton in England, and afterwards miniſter of the firſt church here. Boſton was greatly damaged by an earthquake in October 29, 1727, and ſince that time has ſuffered ſeverely by numerous fires, the houſes being moſtly built of wood. The laſt large fire happened July 30, 1794, and conſumed 96 houſes, rope-walks, &c. and the account of loſſes given in by the ſufferers amounted to 209,861 dollars.

It was in Boſton that the Revolution originated which gave independence to America, and from thence flew like an electrical ſhock throughout the Union. It ſuffered much at the commencement of the war, by the loſs of an extenſive trade, and other calamities. Boſton feels a pride in having given birth to Benjamin Franklin, and a number of other patriots, who were among the moſt active and influential characters in effecting the revolution.

BOSWELL (James), known to the learned world as the author of a life of Dr Johnſon and of ſeveral other valuable works, was born, we believe, at Auchinleck in Ayrſhire, in 1740. The family from which he ſprung was ancient and honourable. At the time of his birth his father was a well employed lawyer at the Scotch bar; but was afterwards raiſed to the dignity of Judge, and filled that important ſtation with acknowledged learning, probity, and honour. His title was Lord Auchinleck, taken from his family inheritance; and he died in 1782: on which occaſion Dr Johnſon wrote an elegant and inſtructive letter to the ſubject of this brief memorial; of which we ſhall tranſcribe a paſſage that alludes to ſome ſlight domeſtic differences, which did not happen in vain, ſince they gave riſe to ſuch ſalutary advice:

"Your father's death had every circumſtance that could enable you to bear it. It was at a mature age, and it was expected; and as his general life had been pious, his thoughts had, doubtleſs, for many years paſt, been turned upon eternity. That you did not find him ſenſible muſt doubtleſs grieve you: his diſpoſition towards you was undoubtedly that of a kind, though not of a fond father. Kindneſs, at leaſt actual, is in our own power, but fondneſs is not; and if, by negligence or imprudence, you had extinguiſhed his fondneſs, he could not at will rekindle it. Nothing then remained between you but mutual forgiveneſs of each other's faults, and mutual deſire of each other's happineſs."

The occaſion of this family diſſention is unknown to us. It might originate in the difference of their political principles, Mr Boſwell being a zealous Tory, and his father, as he repreſents him, a rancorous Whig; or it may have ariſen from the celebrated Douglas cauſe, which ſet many friends at variance in Scotland, and in which Lord Auchinleck and his ſon took oppoſite ſides. The Judge gave his vote on the bench for the Duke of Hamilton; and the advocate (for Mr Boſwell was then at the bar) was ſo keen a partizan of Douglas, that when the cauſe was finally decided by the Houſe of Peers,

Peers, he got poffeffion of a Chinefe *gong*, and, at the head of a number of young men and boys patrolled the ftreets of Edinburgh, and made a loud and exulting noife at the windows of his father's houfe, where there was no fymptom difplayed of the general joy.

In 1762 Mr Bofwell made his firft journey to London; where, under the aufpices of Dodfley the bookfeller, he publifhed, "The Cub at Newmarket, a Tale." By the title of *Cub* he meant to characterize himfelf, as the reader will perceive in the following lines, which we fhall give as a fpecimen of the poem:

> Lord Eglintoune, who loves, you know,
> A little dafh of whim, or fo,
> By chance a curious Cub had got,
> On Scotia's mountains newly caught.

During his ftay in London, Mr Bofwell was introduced to Dr Johnfon, with whom it is well known he continued to live in intimacy from that time till Johnfon's death in 1784; and this intimacy procured him the friendfhip of Burke, Goldfmith, Sir Jofhua Reynolds, and many other men of eminence, who compofed what was called *The Literary Club*. In the latter end of 1765 he became acquainted with General Paoli when on his travels; and after his return he publifhed, in 1768 or 1769, his account of Corfica, with the "Journal of a Tour to that Ifland."

Of this work, which gained him fome diftinction in the world, his great friend Johnfon writes thus: "Your hiftory is like all other hiftories, but your journal is in a very high degree curious and delightful. There is between the hiftory and the journal that difference which there will always be found between notions borrowed from without and notions generated within. Your hiftory was copied from books; your journal rofe out of your own experience and obfervation. You exprefs images which operated ftrongly upon yourfelf, and you have impreffed them with great force upon your readers. I know not whether I could name any narrative by which curiofity is better excited or better gratified."

In 1770 Mr Bofwell, who was then in good practice at the Scotch bar, married an amiable woman, by whom he had two fons and three daughters, who furvived him. In 1773 he was chofen a member of the Literary Club; and in the autumn of the fame year he vifited the Hebrides in company with his illuftrious friend Johnfon; after whofe death he publifhed a very entertaining account of their tour, the places they faw, the characters with whom they converfed, and their own remarks on the different converfations. To many perfons, both in England and Scotland, this book gave great offence, as it brought before the public the unguarded talk of private focial circles; but it furely furnifhed much entertainment, as it exhibited a more faithful picture of Hebridian manners than the Britifh public had ever before feen.

In 1784, when Mr Fox's famous India bill was before Parliament, Mr Bofwell publifhed a "Letter to the People of Scotland on the Prefent State of the Nation;" in which he contends, that no charter would be fafe if that bill fhould pafs into a law; and more than infinuates, that the principle of it was equally inimical to the liberties of the fubject and to the prerogative of the king. Dr Johnfon feems to have thought of that bill as he did; for having read the letter, he writes to the author his approbation of it in the following words: "I am very much of your opinion; and, like you, feel great indignation at the indecency with which the king is every day treated. Your paper contains very confiderable knowledge of the hiftory and of the conftitution, very properly produced and applied."

In 1785 Mr Bofwell quitted the Scotch bar, and went to refide in London, where he continued till the day of his death. Having entered himfelf in one of the inns of court, and ftudied the Englifh law, he became a barrifter in England: but we have reafon to believe that his practice there was not fo fuccefsful as it had been in his own country. He enjoyed, however, more completely than he could do in Edinburgh, the converfation of the great, the wife, the witty, and the good; and fuch converfation he always valued above wealth. He frequently vifited his native country, and efpecially Auchinleck, the feat of his anceftors; and foon after his return from one of thofe vifits he was feized with a diforder which proved fatal, on Tuefday the 19th of May 1795.

Such were the principal events in the life of Mr Bofwell. Of his character, it would be difficult to fay *much more* than he has faid himfelf in his "Journal of a Tour to the Hebrides;" and which may, with fome propriety, be copied here:

"I have given a fketch of Dr Johnfon. My readers may wifh to know a little of his fellow-traveller. Think, then, of a gentleman of ancient blood; the pride of which was his predominant paffion. He was then in his 33d year, and had been about four years happily married. His inclination was to be a foldier; but his father, a refpectable Judge, had preffed him into the profeffion of the law. He had travelled a good deal, and feen many varieties of human life. He had thought more than any body fuppofed, and had a pretty good ftock of general learning and knowledge. He had all Dr Johnfon's principles, with fome degree of relaxation. He had rather too little than too much prudence; and his imagination being lively, he often faid things of which the effect was very different from the intention. He refembled fometimes

'The beft good man, with the worft-natur'd mufe.'

"He cannot deny himfelf the vanity of finifhing with the encomium of Dr Johnfon, whofe friendly partiality to the companion of this tour reprefents him as one 'whofe acutenefs would help my inquiry, and whofe gaiety of converfation, and civility of manners, are fufficient to counteract the inconveniences of travel, in countries lefs hofpitable than we have paffed."

Few of Mr Bofwell's friends, we believe, could add much to this candid confeffion. His enemies, if he had any, might dwell upon his failings; but his failings were few, and injurious to no perfon. In his character good nature was predominant. He appeared to entertain fentiments of benevolence to all mankind, and to be incapable of *intentionally* injuring a human being. His converfation-talents were always pleafing, and often fafcinating. But can we wonder at this in him who, with a capacity to learn, had been the companion of Johnfon for more than 20 years? His attachment to the Doctor for fo long a period was a meritorious perfeverance in the defire of knowledge. To it the world is indebted for the moft finifhed picture of an eminent man that ever was executed. We know there are objections to the *mode* of giving the life of Johnfon. It has been thought that ignorance has been wantonly expofed, and the privacy of focial life endangered. We fhall not enter deeply into this queftion. All that we can certainly affirm is, that the work has been read with avidity and pleafure; and that he who does not wifh to read it again may be fufpected to be deficient in tafte and in temper.

Mr Bofwell has been accufed of vanity; but when this accufation is brought againft him, it fhould not be forgotten that he enjoyed advantages which rendered that confpicuous in him from which no man can claim an exemption. We know not the man who would not have been vain to poffefs fo much of Dr Johnfon's converfation, and proud to give it to the world, in hopes that he who venerated Johnfon would not be unthankful to his biographer. From the Doctor, however, he appeared to his friends to have imbibed a portion of melancholy, of which indeed he complained himfelf during the laft two or three years of his life; and he flew for relief where perhaps it is beft to be found, to the fociety of the learned and the gay. Here, as he confeffes, he had rather *too little* than too much *prudence*;" and, with more attachment to the activity of rural life, he might, probably, have lengthened his days. But as his "belief in revelation was unfhaken," and his religious impreffions deep, and recurring frequently, let us hope that he has now attained that ftate from which imperfection and calamity are alike excluded.

BOTANY-BAY, See *New Holland*, Encycl.; and *New South Wales* in this Supplement.

BOTETOURT, a county in Virginia, on the Blue Ridge, W. of which are the Sweet Springs, about 42 miles from the Warm Springs. Its chief town is Fincaftle.—*Morse.*

BOUDOIR, LE, a fmall ifland in the Pacific Ocean, S. lat. 17. 52. W. long. from Paris, 15. 25.; difcovered April 2, 1768, by Bouganville. This ifland, the year before, had been difcovered by Wallis, and named *Ofnaburg*.—The natives call it *Maitea*, according to the report of Capt. Cook, who vifited it in 1769. Quiros difcovered this ifland in 1606, and called it *la Dezana*.—*ib.*

BOUGUER (Peter), an eminent mathematician and mechanical philofopher, was born at Croific, in Lower Bretagne, on the 10th of February 1698. His father John Bouguer, who was likewife a confiderable mathematician, was then profeffor royal of hydrography at that port; and under him young Bouguer ftudied mathematics, and the application of them to fhip-building, almoft from the period when he began to fpeak; fo that he was a proficient in thefe fciences before he had reached beyond the years of childhood. He was, however, removed from Croific to the Jefuits college at Vannes, where at 13 years of age, he triumphed, in a public conteft, over a profeffor of mathematics, who had advanced a mathematical propofition erroneoufly. Two years after this he loft his father, whom he was appointed to fucceed in the office of hydrographer, after being publicly examined, and giving the moft complete proof of his being duly qualified to fill the vacant chair. He was indeed qualified by prudence as well as by fcience; for however furprifing it may be, he filled it both with dignity and with abilities, though then not more than 15 years of age.

In the years 1727, 1729, and 1731, he gained the prizes fucceffively propofed by the Academy of Sciences for effays on the beft way of equipping fhips with mafts, on the beft method of obferving at fea the height of the ftars, and on the moft advantageous way of obferving the declination of the magnetic needle or the variation of the compafs. In 1729 he publifhed an *Optical Effay upon the Gradation of Light*, in which he examined the intenfity of light, and determined its degrees of diminution in paffing through different pellucid mediums, and particularly in traverfing the earth's atmofphere. Of this effay, which was written upon a fubject that till then had not attracted the attention of philofophers, the reader will find fome account in the *Encyclopædia*, under the title Optics, n° 32, &c.

In 1730 Bouguer was removed from the port of Croific to that of Havre. In 1731 he obtained, in the Academy of Sciences, the place of affociate geometrician, vacant by the promotion of Maupertuis to that of penfioner; and in 1735 he was promoted to the office of penfioner aftronomer. The fame year he was fent on the commiffion to South America, along with Meffrs Godin, Condamine and Jeuffieu, to determine the meafure of the degrees of the meridian, and the figure of the earth. In this painful and troublefome bufinefs of ten years duration, chiefly among the lofty Cordelier mountains, our author, befides attending to the object of the voyage, made many fcientific obfervations, viz. on the effect of the Cordeliers on the polarity of the magnetic needle; on the expanfion and contraction of metals and other fubftances, by the fudden and alternate changes of heat and cold among thofe mountains; and on the refraction of the atmofphere from the tops of the fame, with the fingular phenomenon of the fudden increafe of the refraction, when the ftar can be obferved below the line of the level. He likewife afcertained the laws of the denfity of the air at different heights, from obfervations made at different points of thofe enormous mountains; he difcovered that the mountains have an effect upon a plummet, though he did not affign the quantity of that effect; he found out a method of eftimating the errors committed by navigators in determining their route; gave a new conftruction of the log for meafuring a fhip's way; and made feveral other ufeful improvements. M. Bouguer made at different times fome important experiments on the famous reciprocation of the pendulum; he invented in 1747 the heliometer (fee that article *Encycl.*); and made many difcoveries relating to the intenfity of light (for which fee Optics-*Index*, Encycl.) His unremitting application to ftudy undermined his health, and he died on the 15th of Auguft 1758, in the 61ft year of his age.

Of his works which have been publifhed, the chief are, 1. The Figure of the Earth, determined by the Obfervations made in South America, 1749, in 4to. 2. Treatife on Navigation and Pilotage, Paris, 1752, in 4to. This work has been abridged by M. La Caille, in one volume 8vo, 1768. 3. Treatife on Ships, their Conftruction and Motions, in 4to, 1756. 4. Optical Treatife on the Gradation of Light, firft in 1729, then a new edition in 1760, in 4to.

His papers that were inferted in the Memoirs of the

Academy are very numerous and important: as in the Memoirs for 1726, comparifon of the force of the folar and lunar light with that of candles: 1731, obfervations on the curvilinear motion of bodies in mediums; 1732, upon the new curves called the *lines of purfuit;* 1733, to determine the fpecies of conoid, to be conftructed upon a given bafe which is expofed to the fhock of a fluid, fo that the impulfe may be the leaft poffible; determination of the orbit of comets; 1734, comparifon of the two laws which the earth and the other planets muft obferve in the figure which gravity caufes them to take; on the curve lines proper to form the arches in domes; 1735, obfervations on the equinoxes; on the length of the pendulum; 1736, on the length of the pendulum in the torrid zone; on the manner of determining the figure of the earth by the meafure of the degrees of latitude and longitude; 1739, on the aftronomical refractions in the torrid zone; obfervations on the lunar eclipfe of the 8th September 1737, made at Quito; 1744, fhort account of the voyage to Peru by the members of the Royal Academy of Sciences, to meafure the degrees of the meridian near the equator, and from thence to determine the figure of the earth; 1745, experiments made at Quito and divers other places in the torrid zone, on the expanfion and contraction of metals by heat and cold; on the problem of the mafting of fhips; 1746, treatife on fhips, their ftructure and motions; on the impulfe of fluids upon the fore parts of pyramidoids, having their bafe a trapezium; continuation of the fhort account given in 1744 of the voyage to Peru for meafuring the earth; 1747, on a new conftruction of the log, and other inftruments for meafuring the run of a fhip; 1748, of the diameters of the larger planets; the new inftrument called a *heliometer*, proper for determining them, with obfervations of the fun; obfervation of the eclipfe of the moon the 8th of Auguft 1748; 1749, fecond memoir on aftronomical refractions, obferved in the torrid zone, with remarks on the manner of conftructing the tables of them; figure of the earth determined by MM. Bouguer and Condamine, with an abridgement of the expedition to Peru; 1750, obfervation of the lunar eclipfe of the 13th December 1750; 1751, on the form of bodies moft proper to turn about themfelves, when they are pufhed by one of their extremities, or any other point; on the moon's parallax, with the eftimation of the changes caufed in the parallaxes by the figure of the earth; obfervation of the lunar eclipfe the 2d of December 1751; 1752, on the operations made by feamen called *corrections;* 1753, obfervation of the paffage of Mercury over the fun the 6th of May 1753; on the dilatations of the air in the atmofphere; new treatife of navigation, containing the theory and practice of pilotage, or working of fhips; 1754, operations, &c. for diftinguifhing, among the different determinations of the degree of the meridian near Paris, that which ought to be preferred; on the direction which the ftring of a plummet takes; folution of the chief problems in the working of fhips; 1755, on the apparent magnitude of objects; fecond memoir on the chief problems in the working of fhips; 1757, account of the treatife on the working of fhips; on the means of meafuring the light.

BOURBON *Co.* in Kentucky, between Licking and Kentucky rivers, contains 7837 inhabitants, including 908 flaves.—*Morse.*

BOURBON, a poft town and capital of the above county, ftands on a point of land formed by two of the fouthern branches of Licking River; 22 miles N. E. of Lexington, 21 eafterly of Lebanon, and 749 W. S. W. from Philadelphia, and contains about 60 houfes, a Baptift church, a court-houfe and goal. There are feveral valuable mills in its vicinity.—*ib.*

BOW, is a townfhip in Rockingham co. New-Hampfhire, on the W. bank of Merrimack River, a little S. of Concord. It contains 568 inhabitants. —*ib.*

BOWDOIN, a townfhip in Lincoln co. Diftrict of Maine, on the N. eaftern bank of Androfcoggin River; diftant from York, N. eafterly, 36 miles, and from the mouth of Kennebeck River 6 miles, and 166 N. E. of Bofton. It contains 983 inhabitants.—*ib.*

BOWDOINHAM, a townfhip in Lincoln co. diftrict of Maine, feparated from Pownalborough E. and Woolwich S. E. by Kennebeck River. It has 455 inhabitants, and lies 171 miles N. E. from Bofton.—*ib.*

BOWLING *Green*, a village in Virginia, on the poft road, 22 miles S. of Fredericksburg, 48 N. of Richmond, and 25 N. of Hanover court-houfe.—*ib.*

BOXFORD, a fmall townfhip in Effex co. Maffachufetts, having 925 inhabitants. It lies on the S. E. fide of Merrimack River, 7 miles wefterly of Newburyport. In the fouthernmoft of its two parifhes is a bloomery.—*ib.*

BOYLSTON, a townfhip in Worcefter co. Maffachufetts, having 839 inhabitants; 10 miles N. E. of Worcefter, and 45 N. W. of Bofton. It was incorporated in 1786, having been a parifh of Shrewfbury fince 1742; and contains by furvey, 14,396 acres of land, well watered, and of a rich foil.—*ib.*

BRADDOCK's *Field*, the place where Gen. Braddock, with the firft divifion of his army, confifting of 1400 men, fell into an ambufcade of 400 men, chiefly Indians, by whom he was defeated and mortally wounded, July 9, 1755. The American militia, who were difdainfully turned in the rear, continued unbroken and ferved as a rear guard, and, under Col. Wafhington, the late Prefident of the U. S. A. preferved the regulars from being entirely cut off. It is fituated on Turtle Creek, on the N. E. bank of Monongahela River, 6 miles E. S. E. from Pittfburg.—*ib.*

BRADDOCK's *Bay*, on the S. fide of Lake Ontario, 42 miles W. from Great Sodus, and 65 E. from Fort Niagara.—*ib.*

BRADFORD, *Eaft* and *Weft*, are townfhips in Chefter co. Pennfylvania.—*ib.*

BRADFORD, a townfhip in Effex co. Maffachufetts, fituated on the S. fide of Merrimack River, oppofite Haverhill, and 10 miles W. of Newburyport. It has two parifhes, and 1371 inhabitants. Quantities of leather fhoes are made here for exportation; and in the lower parifh fome veffels are built. Several ftreams fall into the Merrimack from this town, which fupport a number of mills of various kinds.—*ib.*

BRADFORD, a townfhip in Hillfborough co. New-Hampfhire, containing 217 inhabitants, incorporated in 1760; 20 miles E. of Charleftown.—*ib.*

BRADFORD, a townfhip in Orange co. Vermont, on the W. bank of Connecticut River, about 20 miles above Dartmouth College, having 654 inhabitants. There is a remarkable ledge of rocks in this townfhip, as much as 200 feet high. It appears to hang over, and threaten the traveller as he paffes. The fpace between this ledge and Connecticut River is fcarcely wide enough for a road.—*ib.*

BRAINTREE, a townfhip in Orange co. Vermont, lies 75 miles N. eaftward of Bennington. It joins Kingfton weftward, Randolph on the eaftward, and contains 221 inhabitants.—*ib.*

Braintree, one of the moft ancient townfhips in Norfolk co. in the ftate of Maffachufetts, was fettled in 1625, and then called *Mount Woolafton*, from the name of its founder. It lies on a bay, 8 miles E. of S. from Bofton, and contained, before its divifion, 400 houfes and 2771 inhabitants. Great quantities of granite ftones are fent to Bofton from this town for fale. The bay abounds with fifh and fea fowl, and particularly *brants*. This town is noted for having produced, in former and latter times, the firft characters both in church and ftate; and, in diftant ages, will derive no fmall degree of fame, for having given birth to John Adams, the firft Vice-Prefident, and the fecond Prefident of the *United States of America*; a man highly diftinguifhed for his patriotifm, as a citizen; his juftice, integrity, and talents, as a lawyer; his profound and extenfive erudition, as a writer; and his difcernment, firmnefs, and fuccefs, as a foreign minifter and ftatefman.—*ib.*

BRANDON, a harbor on the N. fide of Long Ifland, New-York, 9 miles W. of Smithtown, and the fame diftance from Hampftead Plain.—*ib.*

Brandon, a townfhip in Rutland co. Vermont, fituated on both fides of Otter Creek, containing 637 inhabitants, and is about 60 miles northerly from Bennington. Here Brandon Creek empties into Otter Creek from the N. E.—*ib.*

BRANDYWINE *Creek*, falls into Chriftiana Creek from the northward, at Wilmington, in Delaware ftate, about 25 miles from its N. and N. weftern fources, which both rife in Chefter co. Pennfylvania. This Creek is famous for a bloody battle, fought Sept. 11, 1777, between the Britifh and Americans, which lafted nearly the whole day, and the latter were defeated with confiderable lofs: but it was far from being of that decifive kind which people had been led to expect, in the event of a meeting between the hoftile armies, on nearly equal terms, both as to numbers, and the nature of the ground on which each army was fituated. It was fought at Chadds Ford, and in the neighbourhood of, and on, the ftrong grounds at Birmingham church.—*ib.*

Brandywine, a townfhip in Chefter co. Pennfylvania.—*ib.*

BRANDFORD, a townfhip in New-Haven co. Connecticut, confiderable for its iron works. It lies on the S. fide of a river of the fame name, which runs into Long Ifland found, 10 miles E. from New-Haven, and 40 S. of Hartford.—*ib.*

BREAD is fo effential an article of food that every ufeful method of making it fhould be generally known. Much has accordingly been faid on that fubject *(Encycl.)* under the titles Baking, Barm, Bread, and Yeast; but, fince the laft of thefe articles was publifhed, we have feen, in Dr Townfon's *Travels in Hungary*, a method of making bread at Debretzen; of which, as it may fometimes be adopted with advantage in this country, an account may, with propriety, be inferted here.

In the baking of this bread, a fubftitute is ufed for yeaft, which is thus made: Two good handfuls of hops are boiled in four quarts of water: this is poured upon as much wheaten bran as can be well moiftened by it: to this are added four or five pounds of leaven; when this is only warm, the mafs is well worked together to mix the different parts. This mafs is then put in a warm place for 24 hours; and after that it is divided into fmall pieces, about the fize of a hen's egg, or a fmall orange, which are dried by being placed upon a board, and expofed to a dry air, but not to the fun; when dry, they are laid by for ufe, and may be kept a half year. This is the ferment; and it may be ufed in the following manner: For a baking of fix large loaves, fix good handfuls of thefe balls, broken into fragments, are taken and diffolved in feven or eight quarts of warm water. This is poured through a fieve into one end of the bread-trough, and three quarts more of warm water are poured through the fieve after it, and what remains in the fieve is well preffed out. This liquor is mixed up with fo much flour as to form a mafs of the fize of a large loaf: this is ftrewed over with flour; the fieve, with its contents, is put upon it, and then the whole is covered up warm, and left till it has rifen enough, and its furface has begun to crack: this forms the leaven. Then 15 quarts of warm water, in which fix handfuls of falt have been diffolved, are poured through the fieve upon it, and the neceffary quantity of flour is added, and mixed and kneaded with the leaven: this is covered up warm, and left for about an hour. It is then formed into loaves, which are kept in a warm room half an hour; and after that they are put in the oven, where they remain two or three hours, according to the fize. The great advantage of this ferment is, that it may be made in great quantities at a time, and kept for ufe. Might it not on this account be ufeful on board of fhips, and likewife for armies when in the field?

Bread, in whatever way it is made, is a dear article, and it may be a defirable object to many of our readers to know at what price the baker can afford to fell it. This depends upon the price of wheat, the quantity of flour which the wheat may give, the lofs at the mill, the expence of grinding, and the expence of baking.

Of the price of wheat we can fay nothing with precifion, becaufe it varies according to the goodnefs or badnefs of the crop, and other circumftances; but a bufhel of Effex wheat, Winchefter meafure, may be taken, on an average, as weighing 60 lb. Sixty pounds of wheat will yield, exclufive of the lofs in grinding and dreffing, 45½ lb. of that kind of flour which is called *feconds*; which alone is ufed, through the greateft part of England, for bread, and which makes, indeed, the beft of all bread, though not the whiteft. A peck of this flour, weighing 14 lb. will take up between fix and feven pints of water, and give 18 lb. of excellent bread; or a bufhel of flour, weighing 56 lb. will yield 72 lb. of bread. The expence of baking a bufhel of fuch flour is, in Effex and fome other Englifh counties, about ninepence; viz. yeaft, on an average, twopence; falt, before the late tax, one halfpenny; and baking, fixpence.

But

Bread.

But *ſeconds* is not all that is got from wheat. A buſhel of 60 lb. of wheat gives, beſides $45\frac{1}{2}$ lb. of ſeconds, 13 lb. of offal, i. e. of *pollards* and *bran;* for the utmoſt loſs in grinding and dreſſing a buſhel of wheat ſhould not exceed 1 pound 8 ounces. The millers, indeed, uſually reckon on two pounds of loſs; but we can ſay, with the utmoſt confidence, that the actual loſs is rather leſs than we have ſtated it. A correſpondent of ours, on whoſe accuracy we can depend, weighed, in 1795, two buſhels, Wincheſter meaſure, the one of white and the other of red wheat, and found the weight of them both to be 122 lb. This wheat was ground by his own ſervants, and it yielded $121\frac{1}{2}$ pounds of meal, ſo that there was here but $\frac{1}{2}$ lb. loſt of two buſhels, or of 122 lb. in grinding. He admits that he ſuffered the ſtones to turn too cloſe, and that the loſs ſhould therefore have been ſomewhat greater. The meal was dreſſed, as the wheat had been ground, under his own eye; and every poſſible precaution being taken to prevent his being deceived in the reſult, he had of flour, or *ſeconds*, $93\frac{1}{2}$ lb. and of bran and pollard $25\frac{1}{2}$ lb. ſo that he loſt, of two buſhels, but $2\frac{1}{2}$ lb. both in grinding and dreſſing. The offal, or bran and pollard, being dreſſed in a bolting mill, yielded as follows:

Sharps -	6 lb.	0 oz.
Fine pollard	5	8
Coarſe pollard	7	8
Broad bran	5	8
Altogether	24	8

There was loſt, therefore, in bolting, only one pound; and of the ſharps, about three pounds, if ſifted, would have been good flour. Indeed were the ſharps and fine pollard to be added to the flour, the bread would, perhaps, be better, and more wholeſome, than without ſuch addition. From theſe data, which we believe to be very accurate, it will be eaſy to calculate, if the price of wheat be given, what ſhould be the price of flour per buſhel and peck, the price of bread per pound, and the quantity of bread that ſhould be ſold for a ſhilling.

It is a fact, however, which ſhould be attended to, that loaves are not always of the ſame weight, though made of equal quantities of the very ſame dough. This was fully aſcertained ſome years ago at Paris. On a violent complaint that the bread was not always of the ſame ſtandard weight, the bakers of the city were called before the police officers. They admitted the fact, that loaves, baked at the ſame time, and in the ſame oven, were ſeldom, if ever, of the ſame weight; but they inſiſted, that they contained, each, the ſtandard quantity of dough, and that the variety of weight among them muſt proceed from ſome cauſe, which they did not pretend to aſcertain. The matter was referred to the Royal Academy of Sciences, which appointed one of its members to ſuperintend, for ſome days, the whole proceſs of baking. This being done it was found, that, of loaves baked in a large oven, thoſe were always heavieſt which occupied the centre of the oven, and that the bakers were innocent of the crime with which they were charged. The fact, we think, may eaſily be accounted for. Even in an oven there muſt be ſome condenſation of ſteam; and, from the very ſhape of the oven, the greateſt quantity muſt be condenſed towards the centre. Hence the loaves in the centre are neceſſarily wetter and heavier than thoſe round the circumference, if the plain of the oven has been equally heated.

Bread.

Bread *of Rice* might occaſionally be of great uſe in many countries during a ſcarcity of wheat; but the method of making it is not generally known. It is indeed impoſſible to make bread of the flour of rice, which is harſh and dry like ſand or aſhes, by treating it in the manner in which wheat-flour is commonly treated; and therefore it has been propoſed to mix it with an equal quantity of the flour of rye. But this method of uſing the flour of rice is a very uncertain remedy in caſe of want; ſince we can have no rice-bread if we have not rye. We are taught, however, in the *Journal des Sciences, des Lettres, et des Arts*, how to make excellent bread from rice alone, by a method which the author of the memoir ſays he learned from the natives of America.

According to this method of making the wiſhed-for bread, the firſt thing to be done to the rice is, to reduce it to flour, by grinding it in a mill, or, if we have not a mill, it may be done in the following manner: Let a certain quantity of water be heated in a ſaucepan or caldron; when the water is near boiling, let the rice we mean to reduce into flour be thrown into it: the veſſel is then to be taken off the fire, and the rice left to ſoak till the next morning. It will then be found at the bottom of the water, which is to be poured off, and the rice put to drain upon a table placed in an inclined poſition. When it is dry, it muſt be beat to powder, and paſſed through the fineſt ſieve that can be procured.

When we have brought the rice into flour, we muſt take as much of it as may be thought neceſſary, and put it into the kneading-trough in which bread is generally made. At the ſame time we muſt heat ſome water in a ſaucepan or other veſſel, and, having thrown into it ſome handfuls of rice, we muſt let them boil together for ſome time: the quantity of rice muſt be ſuch as to render the water very thick and glutinous. When this glutinous matter is a little cooled, it muſt be poured upon the rice-flour, and the whole muſt be well kneaded together, adding thereto a little ſalt, and a proper quantity of leaven. We are then to cover the dough with warm cloths, and to let it ſtand that it may riſe. During the fermentation, this paſte (which, when kneaded, muſt have ſuch a proportion of flour as to render it pretty firm) becomes ſo ſoft and liquid that it ſeems impoſſible it ſhould be formed into bread. It is now to be treated as follows:

While the dough is riſing, the oven muſt be heated: and, when it is of a proper degree of heat, we muſt take a ſtewpan of tin, or copper tinned, to which is fixed a handle of ſufficient length to reach to the end of the oven. A little water muſt be put into this ſtewpan, which muſt then be filled with the fermented paſte, and covered with cabbage or any other large leaves, or with a ſheet of paper. When this is done, the ſtewpan is to be put into the oven, and puſhed forward to the part where it is intended the bread ſhall be baked; it muſt then be quickly turned upſide down. The heat of the oven acts upon the paſte in ſuch a way as to prevent its ſpreading, and keeps it in the form the ſtewpan has given it.

In this manner pure rice-bread may be made; it

comes

comes out of the oven of a fine yellow colour, like paſtry which has yolk of eggs over it. It is as agreeable to the taſte as to the ſight; and may be made uſe of, like wheat-bread, to put into broth, &c. It muſt, however, be obſerved, that it loſes its goodneſs very much as it becomes ſtale.

It may be here remarked, that the manner in which Indian corn is uſed in ſome countries, for making bread, can only produce (and does in fact produce) very bad dough, and of courſe very bad bread. To employ it advantageouſly, it ſhould be treated like rice; and it may then be uſed, not only for making bread, but alſo for paſtry.

BREAKNECK *Hill*, oppoſite Butterhill, at the northern entrance of the highlands, in Hudſon River, about 60 miles N. of New-York. On the S. ſide of this hill, about half the diſtance as you aſcend it, the rocks are ſo ſituated as to give the ſpectator a tolerable idea of a human face, with a noſe, mouth and double chin, but without a forehead. On the noſe grows a tree of conſiderable ſize, which has the appearance only of a ſhrub.—*Morse.*

BREWING is an art of vaſt importance, and has accordingly been explained in the Encyclopædia. A few improvements, however, have been made in the art, which, though not noticed in that Work, ſeem to be worthy of general attention, and, therefore, to deſerve a place in this Supplement. The firſt, of which we ſhall give an account, is an invention of Mr WILLIAM KER of *Kerfield*, in the county of Tweedale, for the ſaving of hops, and, at the ſame time, giving to the liquor, whether ale, beer, or porter, a ſuperior flavour and quality.

The ſteam which ariſes from the boiling copper is known to be ſtrongly impregnated with the eſſential oil of the hops, in which their flavour conſiſts. Inſtead, therefore, of allowing it to eſcape and evaporate, as it does in the common mode of brewing, Mr Ker contrives to preſerve and condenſe it, by means of a winding-pipe fixed to the copper, ſimilar to the worm of a ſtill, or by a ſtraight pipe paſſing through cold water, or any other cooling medium. The oil and water, thus obtained, are returned into the worts when boiled, or the oil, after being ſeparated from the water, along with which it had been exhaled, is returned into the worts after they are boiled; and the watery part, which, after the oil is ſeparated, ſtill continues impregnated with the aromatic taſte and bitter of the hop, is returned into the next copper or boiling-veſſel; and ſo on from one copper or boiling-veſſel into another. By this proceſs a conſiderable part of the hop and flavour, which is loſt in the ordinary mode of brewing, is preſerved: the flavour of the liquor is improved by the preſervation of the finer parts of the aromatic oil: and the ale and beer are better ſecured from any tendency to acidity or putrefaction, and therefore muſt be fitter for home conſumption and exportation. For this invention, which is certainly ſimple, and we think rational, Mr Ker obtained a patent dated March 4. 1788.

On the 4th of June 1790, Mr JOHN LONG of *Longville*, in the county of *Dublin*, Ireland, obtained a patent for an improvement in brewing, reſembling in one particular, this invention of Mr Ker's. To his invention, however, he gives the name of *an entire new method*, in *all the eſſential parts*, of brewing good malt-liquor; and therefore, as it comprehends the whole proceſs of brewing, we ſhall lay it before our readers in the words of its author.

" 1. For the better extracting from malt, place near a maſh-tun a ſhallow copper or other veſſel that will readily heat; the curb of which to be on a level with the tun, and to contain from two to ſix hogſheads, according to the dimenſion of the tun, more or leſs; and, at the lower end of the copper, have a cock from two to five inches diameter, more or leſs, to conduct the heated liquor from the copper into a tube which paſſes down the external part of the tun, and enters it through an aperture about ſix inches from the bottom; then forming two revolutions, more or leſs, through the body of the tun, and communicating its heat to the wort as it paſſes through the tube; and then, at a convenient diſtance from the place it firſt entered, it runs from the tun into a ciſtern or tub, ſituate as near as convenient to the copper or heating-veſſel. In the tub or ciſtern is to be placed a pump, for the purpoſe of conveying the cooler liquor back to the copper or heating-veſſel again; there to receive the heat of 208 degrees, more or leſs (which it will require after the firſt half-hour), and then convey it through the maſhing-tun as before, and in the ſame manner, as long as the working brewer or diſtiller may think neceſſary, to raiſe the maſhing-tun to any degree of heat required. By adhering to the foregoing proceſs, the firſt liquor may, with the greateſt ſafety, be let upon the malt from 20 to 30 degrees lower than the preſent practice; by which means it operates with gentleneſs, opens and expands the malt and raw corn, and prepares it for the reception of ſharper or warmer liquor, ſo as to extract the whole of the ſaccharine quality from the malt and raw corn. By the foregoing method, the maſhing-tun, inſtead of loſing its firſt heat (which it does by the preſent practice), continues to increaſe in heat every moment, by conveying the heated liquor through the tube into the tun; by which means, at the end of two hours, the working brewer or diſtiller can have the tun brought to any degree of heat he ſhall think beſt ſuited to the different qualities of the malt or raw corn. Perſons who would wiſh to ſave expence, may heat their maſhing-tun at the ſide or bottom by a large piece of metallic ſubſtance made fire proof, and fixed therein; which, in ſome degree, will anſwer the end propoſed, but with great trouble and delay.

" 2. To prevent the wort from receiving a diſagreeable flavour while in the under-back, a tube muſt be placed at the cock of the maſhing-tun, to receive the wort as it comes off, and convey it to a great ciſtern or refrigeratory, which is ſupplied with a ſtream of water. The wort, paſſing through that medium in a ſpiral tube, ſoon loſes that heat which ſo often proves prejudicial to the brewer and diſtiller in warm weather: then paſs it from the tube into a veſſel in which pumps are placed, to return the worts into the copper for the purpoſe of boiling off. All veſſels for receiving the cold wort muſt be placed lower than the ſource whence the wort comes.

" 3. As the great object of long boiling the wort is remedied, by my invention of taking the extract from the hops in a ſeparate manner from the worts, I boil my worts no longer than from 15 to 20 minutes; and, by purfuing that method, I fave much time and fuel, and regulate my lengths accordingly.

"4. I fteep my hops, the preceding day to which they are to be ufed, in a copper or other veffel, with as much fluid, blood-warm, as will cover the hops, where it is to remain over a flow fire at leaft 14 hours, clofe covered; the copper at the tenth hour not to be of a greater heat than 175 degrees, continuing flow until the laft hour. Then I bring the copper gradually to a fimmer or flow boil; in which ftate I let it remain about 10 minutes, and then run off the fluid; and this I do at the fame time the firft wort is boiled off, that they may both pafs together through the refrigeratory into the fermentation or working-tun. After the foregoing operation, I cover the hops again with other liquor, and bring the copper to boil as foon as convenient, and let it remain in that ftate a confiderable time, until the fecond worts are boiled off. Then I pafs the hop-fluid with the wort, the fame as in the firft inftance; and, if there is a third wort, I boil my hops a third time with fmall worts and pafs it off as before; by which means I gradually obtain the whole of the effential oil and pleafing bitter from the hops, which is effectually preferved in the beer.

"5. To cool worts. When the wort is boiled off, it is conducted from the cock of the copper or boiler into a tube of a proper dimenfion, which paffes the wort from the cock to the large ciftern or refrigeratory, and there performs feveral revolutions, in a fpiral manner, through the fame tube; which is immerfed in conftant fupply of cold water, where it lofes the greateft part of its heat in a fhort time, and thence continues a ftraight courfe through the tube, a little elevated and of a fuitable length, placed in brick work, until it meets a fmall refrigeratory, fupplied with colder water from a refervoir made for that purpofe at the head of the works; whence a continual ftream runs on the furface of the tube down to the great refrigeratory, cooling the wort as it paffes, in order to enable the working brewer or diftiller to fend it into the backs or working-tuns at whatever degree of heat he fhall think proper. There is no other difference between brewer and diftiller in this procefs, but that the diftiller immediately paffes the ftrong wort from the mafhing-tun to the back, through the fame machinery above inferted, and the tubes may be made of lead, or any other metallic fubftance.

"6. To enable me to brew in the warm fummer months, I fink my backs or working tuns at leaft to a level with the ground, but if deeper the better, and cover them clofely by an arch made of bricks, or other materials, that will totally exclude the atmofpheric air from them. I place them as near as poffible to a fpring or fand-drain, as their depth will naturally draw the water thence, which muft be fo contrived as to pafs or flow round the backs or tuns. I then introduce a large tube, which paffes through the tuns, and keeps the wort feveral degrees lower than can poffibly be done by the prefent practice; by which means I can produce a complete fermentation even in the dog-days.

"7. In cold or frofty weather, if the tun and backs fhould lofe the firft heat, intended to carry it through the procefs by the foregoing method, you may convey a fupply of warm or boiling water by the tube, which paffes through the body of the backs or tun, communicating its heat. which rifes to any degree the working brewer fhall think proper: by purfuing this method, in the coldeft feafon, I never want a fermentation."

We regret that we cannot with propriety ftate to our readers, under this article, a fummary of Mr Richardfon of Hull's *Philofophical Principles of Brewing*; for as the author has a new edition of his work in the prefs, it is our duty rather to refer to it, than to quote from a former edition, which contains not his laft improvements. See Fermentation and Malt, in this Supplement.

BRIAR *Creek*, a water of Savannah River, in Georgia. Its mouth is about 50 miles S. E by S. from Augufta, and 55 N. wefterly from Savannah. Here Gen. Prevoft defeated a party of 2000 Americans, under Gen. Afh, May 3, 1779; they had above 300 killed and taken, befides a great number drowned in the river and fwamps. The whole artillery, baggage and ftores were taken.—*Morse.*

BRIDEALE. See Scotale in this Supplement.

BRIDGE. See that article *(Encycl.)*, and Arch in this Supplement. A *wooden*-bridge, of large fpan, fhould be conftructed on the principles explained under the title Roof *(Encycl.)* See alfo Centre *(Suppl.)*

BRIDGETOWN, in Cumberland co. diftrict of Maine, having Hebron on the N. W. and Bakerftown (on the W. fide of Androfcoggin River,) on the S. E. which three fettlements lie on the northern fide of Little Androfcoggin River. It contains 329 inhabitants and lies 34 miles N. by N W. from Portland; and 156 N. E. from Bofton. Bridgetown confifts of large hills and vallies: the highland affords red oak, which are often three feet and fometimes four, in diameter; and 60 or 70 feet without any branches. The vallies are covered with rock maple, bafs, afh, birch, pine, and hemlock. There is a curiofity to be feen in Long Pond, which lies moftly in Bridgetown, which may afford matter of fpeculation to the natural philofopher.

On the eafterly fide of the pond is a cove which extends about 100 rods farther E. than the general courfe of the fhore, the bottom is clay, and fo fhoal that a man may wade 50 rods into the pond. On the bottom of this cove are ftones of various fizes, which, it is evident from various circumftances, have an annual motion towards the fhore; the proof of this is the mark or track left behind them, and the bodies of clay driven up before them. Some of thefe ftones are 2 or 3 tons weight, and have left a track of feveral rods behind them; having at leaft a common cart-load of clay before them. The fhore of the cove is lined with thefe ftones, which, it would feem, have crawled out of the water.—*Morse.*

Bridgetown, Cumberland county, New-Jerfey, lies on both fides Cohanzie Creek, 20 miles from its mouth; and veffels of 100 tons can come up here. It has about 50 houfes, and a brifk trade. Another Bridgetown is on the great ftage road, between Philadelphia and New-York, 6 miles W. of Elizabeth town.—*ib.*

Bridgetown, a poft town in Queen Annes co. Maryland, lies on the weftern fide of Tuckahoe Creek, 8 miles E. from Centreville, as far S. E. from Church Hill, and 65 S. W. from Philadelphia.

Alfo the name of a town in Kent co. in the fame ftate, fituated on the N. bank of Chefter River, (which

feparates

feparates this county from that of Ann) 7 miles S. E. from Crofs Roads; and 4 foutherly from Newmarket. —*Morse.*

BRIDGEWATER, a townfhip in Grafton co. New-Hampfhire, incorporated in 1769, and contains 281 inhabitants.—*ib.*

BRIDGEWATER, a townfhip in Somerfet co. New-Jerfey, which contains 2,578 inhabitants, including 377 flaves.—*ib.*

BRIDGEWATER, a confiderable townfhip in Plymouth co. Maffachufetts, containing 4975 inhabitants; 5 miles N. E. from Raynham; about 30 miles E. of S. from Bofton, in which large quantities of hard ware, nails, &c. are manufactured.—*ib.*

BRIDGEWATER, a townfhip in Windfor co. Vermont, about 55 miles N. E. of Bennington, containing 293 inhabitants.—*ib.*

BRIDPORT, a townfhip in Addifon co. Vermont, on the E. fhore of Lake Champlain; about 72 miles N. N. W. from Bennington. It has 449 inhabitants. —*ib.*

BRIMFIELD, a townfhip in Hampfhire co. Maffachufetts, fituated E. of Connecticut River; having 1211 inhabitants; 34 miles S. E. of Northampton, and 75 W. of Bofton.—*ib.*

BRINDLEY (James), was born at Tunfted, in the parifh of Wormhill, Derbyfhire, in 1716. His father was a fmall freeholder, who diffipated his property in company and field amufements, and neglected his family. In confequence, young Brindley was left deftitute of even the common rudiments of education, and till the age of 17 was cafually employed in ruftic labours. At that period he bound himfelf apprentice to one Bennet, a mill-wright at Macclesfield, in Chefhire, where his mechanical genius prefently developed itfelf. The mafter being frequently abfent, the apprentice was often left for weeks together to finifh pieces of works concerning which he had received no inftruction; and Bennet, on his return, was often greatly aftonifhed to fee improvements in various parts of mechanifm, of which he had no previous conception. It was not long before the millers difcovered Brindley's merits, and preferred him in the execution of their orders to the mafter or any other workman. At the expiration of his fervitude, Bennet being grown into years, he took the management of the bufinefs upon himfelf, and by his fkill and induftry contributed to fupport his old mafter and his family in a comfortable manner.

In procefs of time Brindley fet up as a mill-wright on his own account; and by a number of new and ingenious contrivances greatly improved that branch of mechanics, and acquired a high reputation in the neighbourhood. His fame extending to a wider circle, he was employed, in 1752, to erect a water-engine at Clifton, in Lancafhire, for the purpofe of draining fome coal mines. Here he gave an effay of his abilities in a kind of work for which he was afterwards fo much diftinguifhed, driving a tunnel under ground through a rock nearly 600 yards in length, by which water was brought out of the Irwell for the purpofe of turning a wheel fixed 30 feet below the furface of the earth. In 1755 he was employed to execute the larger wheels for a filk mill at Congleton; and another perfon, who was engaged to make other parts of the machinery, and to fuperintend the whole, proving incapable of completing the work, the bufinefs was entirely committed to Brindley; who not only executed the original plan in a mafterly manner, but made the addition of many curious and valuable improvements, as well in the conftruction of the engine itfelf, as in the method of making the wheels and pinions belonging to it. About this time, too, the mills for grinding flints in the Staffordfhire potteries received various ufeful improvements from his ingenuity.

In the year 1756 he undertook to erect a fteam engine, upon a new plan, at Newcaftle-under-Line; and he was, for a time, very intent upon a variety of contrivances for improving this ufeful piece of mechanifm. But from thefe defigns he was, happily for the public, called away to take the lead in what the event has proved to be a national concern of capital importance—the projecting the fyftem of canal navigation. The Duke of Bridgewater, who had formed his defign of carrying a canal from his coal-works at Worfley to Manchefter, was induced by the reputation of Mr Brindley to confult him on the execution of it; and having the fagacity to perceive, and ftrength of mind to confide in, the original and commanding abilities of this felf-taught genius, he committed to him the management of the arduous undertaking. The nature of this enterprife has already been defcribed (*Encycl.* vol. IV. p. 80); it is enough here to mention, that Mr Brindley, from the very firft, adopted thofe leading principles, in the projecting of thefe works, which he ever after adhered to, and in which he has been imitated by all fucceeding artifts. To preferve as much as poffible the level of his canals, and to avoid the mixture and interference of all natural ftreams, were objects at which he conftantly aimed. To accomplifh thefe, no labour or expence was fpared; and his genius feemed to delight in overcoming all obftacles by the difcovery of new and extraordinary contrivances.

The moft experienced engineers upon former fyftems were amazed and confounded at his projects of aqueduct bridges over navigable rivers, mounds acrofs deep valleys, and fubterraneous tunnels; nor could they believe in the practicability of fome of thefe fchemes till they faw them effected. In the execution, the ideas he followed were all his own; and the minuteft, as well as the greateft, of the expedients he employed, bore the ftamp of originality. Every man of genius is an enthufiaft. Mr Brindley was an enthufiaft in favour of the fuperiority of canal navigations above thofe of rivers; and this triumph of art over nature led him to view with a fort of contempt the winding ftream, in which the lover of rural beauty fo much delights. This fentiment he is faid to have expreffed in a ftriking manner at an examination before a committee of the Houfe of Commons, when, on being afked, after having made fome contemptuous remarks relative to rivers, what he conceived they were created for? he anfwered, "to feed navigable canals." A direct rivalry with the navigation of the Irwell and Merfey was the bold enterprize of his firft great canal; and fince the fuccefs of that defign, it has become common, all over the kingdom, to fee canals accompanying, with infulting parallel, the courfe of navigable rivers.

After the fuccefsful execution of the Duke of Bridgewater's canal to the Merfey, Mr Brindley was employed in the revived defign of carrying a canal from that river

river to the Trent, through the counties of Chefter and Stafford. This undertaking commenced in the year 1766: and from the great ideas it opened to the mind of its conductor, of a fcheme of inland navigation which fhould connect all the internal parts of England with each other, and with the principal fea-ports, by means of branches from this main ftem, he gave it the emphatical name of the *grand trunk*. In executing this, he was called upon to employ all the refources of his invention, on account of the inequality and various nature of the ground to be cut through: in particular, the hill of Harecaftle, which was only to be paffed by a tunnel of great length, bored through ftrata of different confiftency, and fome of them mere quickfand, proved to be a moft difficult, as well as expenfive, obftacle, which, however, he completely furmounted. While this was carrying on, a branch from the grand trunk, to join the Severn near Bewdley, was committed to his management, and was finifhed in 1772. He alfo executed a canal from Droitwich to the Severn; and he planned the Coventry canal, and for fome time fuperintended its execution; but on account of fome difference in opinion he refigned that office. The Chefterfield canal was the laft undertaking of the kind which he conducted, but he only lived to finifh fome miles of it. There was, however, fcarcely any defign of canal-navigation fet on foot in the kingdom, during the latter years of his life, in which he was not confulted, and the plan of which he did not either entirely form, or revife and improve. All thefe it is needlefs to enumerate; but, as an inftance of the vaftnefs of his ideas, it may be mentioned, that, on planning a canal from Liverpool to join that of the duke of Bridgewater at Runcorn, it was part of his intention to carry it, by an aqueduct bridge, acrofs the Merfey, at Runcorn Gap, a place where a tide, fometimes rifing fourteen feet, rufhes with great rapidity through a fudden contraction of the channel. As a mechanic and engineer, he was likewife confulted on other occafions; as with refpect to the draining of the low lands in different parts of Lincolnfhire and the Ifle of Ely, and to the cleanfing of the docks of Liverpool from mud. He pointed out a method, which has been fuccefsfully practifed, of building fea-walls without mortar; and he was the author of a very ingenious improvement of the machine for drawing water out of mines by the contrivance of a lofing and a gaining bucket.

The intenfity of application which all his various and complicated employments required, probably fhortened his days; as the number of his undertakings, in fome degree, impaired his ufefulnefs. He fell into a kind of chronic fever, which, after continuing fome years, with little intermiffion, at length wore out his frame, and put a period to his life on September 27. 1772, in the 56th year of his age. He died at Tunhurft, in Staffordfhire, and was buried at New Chapel in the fame county.

In appearance and manners, as well as in acquirement, Mr Brindley was a mere peafant. Unlettered, and rude of fpeech, it was eafier for him to devife means for executing a defign than to communicate his ideas concerning it to others. Formed by nature for the profeffion he affumed, it was there alone that he was in his proper element; and fo occupied was his mind with his bufinefs, that he was incapable of relaxing in any of the common amufements of life. As he had not the ideas of other men to affift him, whenever a point of difficulty in contrivance occurred, it was his cuftom to retire to his bed, where, in perfect folitude, he would lie for one, two, or three days, pondering the matter in his mind till the requifite expedient had prefented itfelf. This is that true infpiration which poets have almoft exclufively arrogated to themfelves, but which men of original genius in every walk are actuated by, when, from the operation of the mind acting upon itfelf, without the intrufion of foreign notions, they create and invent.

A remarkably retentive memory was one of the effential qualities which Mr Brindley brought to his mental operations. This enabled him to execute all the parts of the moft complex machine in due order, without any help of models or drawings, provided he had once accurately fettled the whole plan in his mind. In his calculations of the powers of machines, he followed a plan peculiar to himfelf; but, indeed, the only one he could follow without inftruction in the rules of art. He would work the queftion fome time in his head, and then fet down the refult in figures. Then taking it up in this ftage, he would again proceed by a mental operation to another refult; and thus he would go on by ftages till the whole was finifhed, only making ufe of figures to mark the feveral refults of his operations. But though, by the wonderful powers of native genius, he was thus enabled to get over his want of artificial method to a certain degree, yet there is no doubt that when his concerns became extremely complicated, with accounts of various kinds to keep, and calculations of all forts to form, he could not avoid that perplexity and embarraffment which a readinefs in the proceffes carried on by pen and paper can alone obviate. His eftimates of expence have generally proved wide of reality; and he feems to have been better qualified to be the contriver, than the manager, of a great defign. His moral qualities were, however, highly refpectable. He was far above envy and jealoufy, and freely communicated his improvements to perfons capable of receiving and executing them; taking a liberal fatisfaction in forming a new generation of engineers able to proceed with the great plans in the fuccefs of which he was fo deeply interefted. His integrity and regard to the advantage of his employers were unimpeachable. In fine, the name of Brindley will ever keep a place among that fmall number of mankind who form eras in the art or fcience to which they devote themfelves, by a large and durable extenfion of its limits.

BRISSOT (J. P.), acted fo confpicuous a part in the French revolution, that a fair detail of the principal events of his life would undoubtedly be acceptable to all our readers. A fair detail, however, of fuch a life, we believe it impoffible at prefent to give; for characters like Briffot's are almoft always mifreprefented both by their friends and by their enemies; and till the troubles which they have excited, or in which they have been engaged, have long fubfided, the impartial truth is nowhere to be found.

In a fulfome panegyric, under the denomination of *The Life of J. P. Briffot*, faid to be written by himfelf, we are told, that he was born January 14, 1754, and that his father was a *traiteur*, or "the keeper of an eating-houfe," but in what place we are not informed.

Our

Briffot. Our anthor, however, affures us, that the old man was in eafy circumftances, and that he employed all the means refulting from them to give to his numerous family a good education. The fubject of this memoir was intended for the bar; but not relifhing the ftudies neceffary to fit him for the profeffion of the law, or, if we choofe to believe him, having a mind too *pure* and *upright* for the ftudy of *chicane*, he relinquifhed the purfuit after five years of drudgery!

To relieve his wearinefs and difguft, he applied himfelf, he fays, to literature and the fciences. The ftudy of the languages was above all others his favourite purfuit. Chance brought him acquainted with two Englifhmen on their travels through France: he learned their language; and this circumftance, he tells us, decided his fate.

" It was at the commencement of my paffion for that language (continues he) that I made the metamorphofis of a diphthong in my name, which has fince been imputed to me as fo heinous a crime. Born the thirteenth child of my family, and the fecond of my brothers in it, I bore, for the fake of diftinction, according to the cuftom of Beauce, the name of a village in which my father poffeffed fome landed property. This village was called *Ouarville*, and Ouarville became the name by which I was known in my own country. A fancy ftruck me that I would caft an Englifh air upon my name: and accordingly I fubftituted, in the place of the French diphthong *ou*, the *w* of the Englifh, which has precifely the fame found." For this puerile affectation, which was certainly not criminal, he juftifies himfelf by the example of the literati of the 16th and 17th centuries, who made no fcruple of Grecifing and Latinifing their appellatives.

Having profecuted his ftudies for two years, he had an application from the Englifh proprietor of a paper then much in circulation, and intitled *Le Courier de l'Europe*. This man having drawn upon himfelf an attack from government, felt and yielded to the neceffity of printing his paper at Boulogne-fur-mer. It was his wifh to render it interefting to the French in the department of mifcellaneous intelligence; which he therefore wifhed to fubmit to the fuperintendency and arrangement of Briffot, who reprefents himfelf as for fome moments hefitating. The profeffion of a journalift, fubject to a licenfer, was repugnant to his principles; yet it fecured his independence, and put into his power the means of profecuting an inveftigation of conftitutions and of the fciences. After fome ridiculous reafoning from the original ftations of *Bayle*, *Poftel*, and *Rouffeau*, he at laft accepted of the employment, and became enamoured of it, " becaufe (fays he) it enabled me to ferve talents and virtue, and, as it were, to inoculate the French with the principles of the Englifh conftitution.

This employment, however, did not laft for any length of time. The plan of the proprietor of the *Courier* was overthrown by adminiftration, and Briffot quitted Boulogne to return to his firft ftudies. Having informed us of this fact, he makes an extravagant pretence to unfullied virtue, and calls upon the inhabitants of the city which he had left to bear witnefs, not only that he had *no vices*, but that he had not even the *feeds* of any one of the vices which his adverfaries, it feems, had laid to his charge.

" Doubtlefs (fays he), too eager to publifh my ideas, I conceived that the proper moment had arrived, and I felt an inclination to commence with an important work. Revolting, from the very inftant of my beginning to reflect, againft religious and political tyranny, I folemnly protefted, that thenceforward I would confecrate my whole life to their extirpation. Religious tyranny had fallen under the redoubled ftrokes of Rouffeau, of Voltaire, of Diderot, and of D'Alembert. It became neceffary to attack the fecond;" and this was a tafk which the vanity of Briffot led him to confider as referved for him.

What Voltaire and his friends meant by religious tyranny, and how they conducted their attacks againft it, are matters, alas! too well known to all Europe; and as our author chofe thefe philofophers for his guides, we might infer, without much degree of miftake, what he underftood by political tyranny, and by what means he meditated its extirpation. But he has not left us to make this difcovery by inference.

" It became neceffary (fays he) to break in pieces the political idol, which under the name of *monarchy*, practifed the moft violent defpotifm; but to attack it openly, was to expofe the affailant without the poffibility of ferving mankind. It was by a fide blow that it was to be wounded moft effectually;" and therefore he refolved to begin his operations by attacking fome of thofe abufes which might be reformed without apparently fhaking the authority of the prince.

Our readers, at leaft the fober part of them, will probably think, that this mode of attack is not peculiar to Briffot, but that it has been practifed, or attempted to be put in practice, by afpiring demagogues in all ages and countries, who have uniformly begun their career of innovation by exciting the public mind againft thofe abufes in government, of which the exiftence cannot wholly be denied. The fubject to which our author thought fit to call the attention of his countrymen, was the criminal jurifprudence: a fubject, fays he, which, with the exception of fome particulars that had been fuccefsfully inveftigated by Beccaria and Servan, no writer had thoroughly confidered in a philofophical point of view. Thinking himfelf fully equal to this tafk, he drew up a general plan; and in the year 1780 publifhed his Theory of Criminal Laws, in two vols 8vo. This work, favourably received by foreigners, applauded by fome journalifts, and pulled to pieces by others, procured him the friendfhip of the warmeft advocates for human liberty, in whofe opinion the defects of his plan were highly pardonable, on account of the energy confpicuous in his remarks. This publication was foon followed by two difcourfes which gained the prize in 1782 at the Academy of Chalons-fur-Marne; the one upon the reform of the criminal laws, and the other on the reparation due to innocent perfons unjuftly accufed.

It is natural to fuppofe that the government beheld with an evil eye thefe writings, which, under pretext of dragging into light the abufes of the criminal laws, infinuated dangerous principles on the nature of government in general.

His next work was intitled, *A Philofophical Library of the Criminal Laws*, in 10 vols; the true object of which was to diffeminate in France thofe principles of liberty

Briſſot. liberty which guided the Engliſh and the Americans in framing and expounding their laws.

But the ſtudy of legiſlation and politics had not entirely drawn him off from that of other ſciences; ſuch as chemiſtry, phyſics, anatomy, theology, &c. Theſe he conſtantly cultivated with ardour; but acknowledges that in each he met with obſcurities, and that in every quarter truth eſcaped from his reſearches. He therefore ſat down to inveſtigate the nature of truth, and the proper method of attaining to it in every department of reſearch; and the reſult of his labours was a kind of *novum organum*, by which he ſeems to have expected that Bacon's work would be buried in oblivion; and to this important volume he gave the title of *Concerning Truth; or Thoughts on the Means of attaining Truth in all the Branches of Human Knowledge*. This volume was meant as nothing more than the introduction to a greater work, in which he propoſed to inveſtigate what is *certain* in knowledge and what *doubtful*, and then to ſtrike the balance of the account.

He was prevented, however, from completing his plan, which he regrets exceedingly; for, as he affirms, with *becoming modeſty*, his work would certainly have amended its readers! But the French government happened to think otherwiſe; his aim, which, he ſays, was to lead mankind to reflect on their rights, was perceived, and he was accuſed to the miniſter as a ſeditious writer. The career of genius was ſtopped by the dread of the Baſtile; and he was obliged to take refuge in London. There it was his wiſh to create *a univerſal confederation of the friends of liberty and truth*, and to eſtabliſh a *centre of correſpondence and union* with the learned and the politicians of Europe. This dark deſign, however, was fruſtrated by the treachery, as it would appear, of his aſſociates, who had bound themſelves, he ſays, by the moſt *ſacred oaths*, to aſſiſt him, and had offered to ſign articles *even with their own blood*.

Finding himſelf unable to proceed directly to the object which he had in view, he reſolved to *enlighten his* countrymen gradually, and to begin with exciting their love and admiration of the Engliſh conſtitution. That conſtitution, which he had inveſtigated on the ſpot, appeared to him a model for thoſe ſocieties which were deſirous of changing their form of government. It was but little known, he ſays, in France (the work of *De Lolme* being at that time only in the hands of the learned); and to make it known was to make it beloved, was to render it deſired. But the French miniſters ſtood upon their guard, and it became neceſſary to *deceive* them. He reſolved therefore to bring forward a journal, written actually in London, and profeſſing to contain only a *deſcription of the ſciences and arts of England*, whilſt the greater part of it was to be occupied in reality by an inveſtigation of the *Engliſh conſtitution*.

After many difficulties, the miniſtry granted a privilege for this journal, being publiſhed in London, to be reprinted in Paris; and it firſt appeared in 1784. "In the twelve numbers which have been publiſhed (ſays the author), the friends of liberty muſt have perceived, that if, on the one ſide, I endeavoured to inculcate more juſt ideas than had hitherto been entertained concerning this celebrated iſland; ſo, on the other, I reſolutely made my advances toward that important end which has perpetually preſided over all my labours, *the univerſal emancipation of men*."

His affairs calling him at this time to Paris, he was arreſted and conveyed to the Baſtile on the 12th of July 1784. In this conduct of the government we cannot perceive any thing very tyrannical or arbitrary, ſince he confeſſes, that in the 16th page of the firſt number of his Journal, he had ſuffered the *ſecret and favourite aim*, which always guided his pen, to become diſcernible. He was, however, diſcharged from priſon on the 5th of September, and returned with increaſed zeal to his former employments. Briſſot.

"This perſecution (ſays he), far from extinguiſhing the ardour of my wiſhes to inculcate the principles of freedom, ſerved only to inflame it the more." Accordingly, in 1785, he publiſhed two letters to the Emperor Joſeph II. *concerning the right of emigration, and the right of people to revolt*. The firſt of theſe letters, which, though well known in Germany, were in France ſuppreſſed by the *police*, was occaſioned by what the author calls the ridiculous and barbarous edict againſt emigration; and the ſecond by the puniſhment of *Horiah* the chief of the *Walachian* inſurgents. In this laſt letter he lays it down as a maxim, that all people under ſuch a government as that of the *Walachians*, have from nature a ſacred *right* to revolt, a right which they can and ought to exerciſe. In the ſame ſpirit he brought out, in 1786, his Philoſophical Letters on the Hiſtory of England, in 2 vols, and A Critical Examination of the Travels of the Marquis de Chatelleux in North America.

The French revolution appearing to him extremely diſtant, notwithſtanding all his efforts to haſten it, he reſolved to leave France for the purpoſe of ſettling in America. His project received the approbation of ſeveral, whoſe ſentiments were congenial with his own. But as it was thought imprudent to tranſport numerous families to a country ſo far off, without thoroughly knowing it, Briſſot was engaged to proceed thither, to examine the different places, to obſerve the inhabitants, and to diſcover where and in what manner the eſtabliſhment they had propoſed might be moſt advantageouſly fixed. He had ſome time before inſtituted a ſociety at Paris for accompliſhing the abolition of the negro trade, and for ſoftening the condition of the ſlaves. At the period of his departure, this ſociety conſiſted of a conſiderable number of diſtinguiſhed members, and he was commiſſioned to carry the firſt fruits of their labours to America. His ſtay there, however, was not ſo long as he was deſirous of making it. In the beginning of 1789 he was recalled by the news of the French revolution, which he conceived might probably produce a change in his own meaſures and in thoſe of his friends. This idea added to other circumſtances, accelerated his return. The fire had blazed forth in his native country. Hope (ſays he) animated every heart; the moſt diſtinguiſhed champions had engaged in the conteſt; I too became deſirous to break a lance, and I publiſhed my *Plan of Conduct for the Deputies of the People*."

This, and other works of a ſimilar kind, of which he loudly boaſts the merits, raiſed him high in the favour of the republican part of the nation, and he became preſident of his diſtrict; where he acted, according to his own account, with great uprightneſs in the municipality, in the firſt committee of enquiries, and as an elector. At laſt he became a member, firſt of the *National Aſſembly*, and after its diſſolution, of the *Sanguinary*

Briftol. *nary Convention*; and by fome means or other got to be the leader of a party called fometimes the *Girondifts*, and fometimes the *Briffotines*. From that period the principal events of his life were involved with the public tranfactions of the nation, of which we have given an account in the *Encyclopædia* under the title Revolution (fee that article, n° 101—182.) The Girondift faction was denounced by the Mountain, and Briffot fuffered by the guillotine on the 30th of November 1793. He fell indeed by a very unjuft fentence; but his fall was the natural confequence of that anarchical tyranny under which no man had contributed more than he to fubject his native country.

BRISTOL, a townfhip in Lincoln co. Diftrict of Maine, having 1718 inhabitants; diftant 204 miles N. E. from Bofton, and 8 N. of Pemaquid Point. —*Morse*.

Bristol, a county in the fouthern part of Maffachufetts, E. of a part of the ftate of Rhode Ifland. It has 15 townfhips, of which Taunton is the chief; and 31,709 inhabitants. The great fachem Phillip refided here; and it was called by the Indians *Pawkunnawkutt;* from which the nation derived the name; but were fometimes ftyled the *Wampoaags*.—*ib*.

Bristol, *Co*. in Rhode Ifland ftate, contains the townfhips of Briftol, Warren, and Barrington; having 3211 inhabitants, inclufive of 98 flaves. It has Briftol co in Maffachufetts, on the N. E. and Mount Hope bay E.—*ib*.

Bristol, a fea-port town, and chief of the above county, lies on the weftern fide of the peninfula called Briftol neck, and on the E. fide of Briftol bay; including Popafquafh neck, and all the N. and E. part of Briftol neck, to Warren, N.; and to Mount Hope bay, E. It is about 3 miles from Rhode Ifland; the ferry from the S. end of the townfhip being included, which is little more than half a mile broad; 13 miles northerly from Newport, 24 S. E. from Providence, and 63 from Bofton.—Briftol fuffered greatly by the ravages of the late war; but is now in a very flourifhing ftate, having 1406 inhabitants, inclufive of 64 flaves. It is beautiful for fituation—a healthful climate—rich foil, and a commodious, fafe harbor. Onions, in confiderable quantities, and a variety of provifions and garden ftuff, are raifed here for exportation. N. lat. .,0. 40.—*ib*.

Bristol, a townfhip in Hartford co. Connecticut, 16 miles W. of the city of Hartford.—*ib*.

Bristol, a town in Bucks co. Pennfylvania, 11 miles S. S. E. from Newtown, and 20 N. E. from Philadelphia. It ftands on Delaware River, oppofite Burlington, in New-Jerfey; and has about 50 or 60 houfes. It is a great thoroughfare, and is noted for its mills of feveral kinds.—*ib*.

Bristol, a townfhip in Philadelphia county.—*ib*.

Bristol, a fmall town in Charles county, Maryland.—*ib*.

Bristol, a townfhip in Addifon co. Vermont, E. of Vergennes, having 211 inhabitants.—*ib*.

Bristol *Bay*, on the N. W. coaft of N. America, is formed by the peninfula of Alafka on the S. and S. E. and by Cape Newnham on the N.; and is very broad and capacious. A river of the fame name runs into it from the E.—*ib*.

Brookfield || Brown.

BROOKFIELD, in the S. W. part of Worcefter co. Maffachufetts, is among the firft towns as to age, wealth and numbers, in the county; containing 3100 inhabitants. The great poft road from Bofton to N. York runs through it. It is 64 miles W. of Bofton and 27 W of Worcefter. The Indian name of this town was *Quaboag*. The river which ftill retains the name paffes through it; and like its other ftreams and ponds, abounds with various kinds of fifh. Here is iron ore, and large quantities of ftone which yield copperas, and have a ftrong vitriolic quality. This town was fettled by people from Ipfwich, in 1660, and was incorporated in 1673.—*ib*.

Brookfield, a townfhip in Orange co. Vermont, has 421 inhabitants, and lies 80 miles northerly from Bennington.—*ib*.

Brookfield, a townfhip in Lincoln co. diftrict of Maine, 14 miles above Norridgewalk on Kennebeck River, and was formerly called *Seven mile Brook*.—*ib*.

Brookfield, a town in Montgomery co. New-York. By the ftate cenfus of 1796, 160 of its inhabitants are electors.

Brookfield, a townfhip in Fairfield co. Connecticut, 6 miles N. N. E. from Danbury.—*ib*.

BROOKHAVEN, a townfhip in Suffolk co. Long Ifland, New-York, containing 3,224 inhabitants. Of thefe 233 are flaves; and by the ftate cenfus of 1796, 535 only are electors. The compact part of the town contains about 40 houfes, an Epifcopalian, and a Prefbyterian church. It is 60 miles E. of New-York.—*ib*.

BROOKLYN, a townfhip in Kings co. New-York, on the W. end of Long Ifland, having 1603 inhabitants; of thefe 405 are flaves; and 224 are electors, by the ftate cenfus of 1796. Here are a Prefbyterian church, a Dutch Reformed church, a powder magazine, and fome elegant houfes which lie chiefly on one ftreet. Eaft River, near a mile broad, feparates the town from New-York.—*ib*.

Brooklin, a townfhip in Wyndham co. Connecticut, about 20 miles N. of Norwich.—*ib*.

BROTHERTON, an Indian village adjoining New-Stockbridge, (N. York) inhabited by about 150 Indians, who migrated from different parts of Connecticut, under the care of the Rev. Mr Occom. Thefe Indians receive an annuity of 2160 dollars, which fum is partly appropriated to the purpofe of maintaining a fchool, and partly to compenfate a fuperintendant, to tranfact their bufinefs, and to difpofe of the remainder of their money for their benefit.—*ib*.

BROWN (Dr John), author of the *Elementa Medicinæ*, &c. was born in the village of Dunfe, or, as fome fay, Lintlaws, in the county of Berwick, in the year 1735-6. His parents were of mean condition, but much refpected in the neighbourhood for the integrity of their lives. His father gained his livelihood in the humble capacity of a day-labourer; while his mother contributed her fhare towards the fupport of the family by the profits arifing from a milch cow.

Such were the perfons who, in an obfcure part of the country, gave birth to a fon deftined, at a future period, to make a diftinguifhed figure in the republic of letters; and from whom originated a fyftem of the animal economy, which, whatever be its real merits, has undoubtedly produced a confiderable revolution in the practice of medicine.

Brown.

At the age of three or four years, young Brown was put to a reading ſchool in Dunſe, which he himſelf commemorates as the place rather of his education than of his nativity. Here, under the tuition of an old woman, he very early began to exhibit marks of that ſtrength of mind for which he was afterwards ſo eminently diſtinguiſhed. In the ſhort period of a year he became able to read with facility any part of the Bible, and acquired over his claſs-fellows that ſuperiority which he ever after maintained both at ſchool and college.

It was almoſt immediately after his entrance into this ſchool, that his inſatiable deſire of reading commenced; and ſo unremitting was his application, that he is ſaid never to have been found, even at thoſe hours which children much more advanced in life devote to amuſement, without a book in his hand.

While he was making this rapid progreſs in the rudiments of literature, he ſuffered what muſt have appeared to be a very heavy loſs in the death of his father; but his mother ſoon afterwards married a worthy man of the ſame name, whoſe care and attention ſupplied the place of a father to her ſon. This man being a weaver, deſigned to educate his ſon-in-law to the ſame buſineſs, and began to inſtruct him in his art when he was about nine years of age, but the taſte which young Brown had already acquired for letters, made him look with diſguſt on the inſipid employment of a weaver. His ſtep-father was no tyrant, and his mother was affectionate. They were both proud of the talents which at ſo early a period of life had appeared in their ſon, and they felt no inclination to ſtruggle with the invincible averſion which he expreſſed to the buſineſs for which they intended him.

Another circumſtance, however, contributed in no ſmall degree to make them recal their original reſolution. They were both of that ſect of religioniſts which in Scotland are called Seceders (ſee Seceders, *Encycl.*); and it was ſuggeſted to them by ſome perſons of their own perſuaſion, who had remarked the uncommon abilities of the boy, that he might one day prove an able ſupport and promoter of their tenets as a preacher. He was accordingly, much to his ſatisfaction, taken away from the buſineſs to which he had conceived ſuch a diſtaſte, and ſent to the grammar-ſchool of Dunſe, which was taught at that time by a gentleman of the name of Cruickſhank, eminent for his grammatical knowledge. Here he appears to have ſpent ſome years with uncommon advantage and happineſs; during which he was eſteemed by all the country round as a kind of prodigy. Like Johnſon, and many other men of the higheſt celebrity, he united in the ſame perſon uncommon powers of mind, with no leſs ſtrength of body, as indeed his appearance indicated; and in his youth he inſured his own perſonal importance among his ſchool-fellows, by excelling them not leſs in athletic exerciſes than in the taſks preſcribed by their maſter. He was particularly fond, when a boy, of practiſing the pugiliſtic art; and indeed until the laſt period of his life he was obſerved by his friends always to view an exhibition of that kind with peculiar reliſh. He alſo prided himſelf much in being a ſtout walker; and mentions his having, in one day, accompliſhed, when but fifteen years of age, a journey of fifty miles between Berwick-upon-Tweed and Morpeth in Northumberland. When farther advanced in life, he travelled on foot from four in the afternoon of one day to two in the afternoon of next day, with the ſhort interval of one hour's reſt! But as one of his biographers very juſtly obſerves, "we have ſeen that he could make a more rational uſe of his ſtrength than merely to ſtake it againſt time and ſpace.*"

His early years while at ſchool were marked by the moſt rigid attachment to his ſect. So ſtrict indeed were his religious ſentiments, if a boy of ten or eleven can be ſaid to have any ſentiments deſerving to be called religious, that he would have conceived the holding of any communion with the eſtabliſhed church as a kind of profanation. An event, however, happened, ſome time between the eleventh and thirteenth years of his age, which produced a total and unexpected revolution in his religious opinions. At a meeting of the provincial ſynod of Merſe and Teviotdale, he was prevailed upon, though not without manifeſting much reluctance, to accompany a party of his ſchool-fellows to the pariſh church of Dunſe. The conſequence of this tranſgreſſion, as he had dreaded, was an immediate ſummons to appear before the ſeſſion of the Seceding congregation; to which, through pride, not chooſing to attend, in order to preclude a formal expulſion, he voluntarily abjured their tenets, and openly avowed his apoſtacy to the eſtabliſhment.

All changes in religion which are not the conſequence of candid inveſtigation are dangerous. He who leaves one ſect he knows not why, will quickly abandon, with as little reaſon, that to which in a fit of paſſion he had haſtily joined himſelf. From the moment of his quitting the communion of the Seceders, Brown's religious ardour ſuffered a gradual abatement; and though, to pleaſe his mother, he continued to proſecute his ſtudies with a view to the office of a clergyman in the church of Scotland, his opinions became daily more and more lax, and his life of courſe leſs and leſs regular. It was, however, a conſiderable time before he admitted, in their full extent, thoſe principles of irreligion which he afterwards avowed; for upon his firſt peruſing the Eſſays of Mr Hume, though his own zeal was then much cooled, he expreſſed great indignation at their dangerous tendency.

At the age of twelve years he had been employed by Mr Cruickſhank as a kind of uſher in the ſchool of Dunſe; and that gentleman having declared that his knowledge of the Latin language was equal to his own, his fame as a ſcholar was ſo ſpread over the country, that at the age of thirteen he was entruſted with the education of a gentleman's ſon in the neighbourhood, when he quitted the ſchool and his beloved maſter. In his new ſituation, however, he remained not long. Dr Beddoes conjectures, that to the ſtiffneſs of pedantry he added the ſourneſs of a bigot, and was therefore a diſagreeable inmate of the family. That a boy of thirteen, proud of his talents, and prouder of his learning, ſhould have the ſtiffneſs of a pedant, is indeed extremely probable; it was the natural conſequence of the praiſe with which he had been honoured by Mr Cruickſhank: but there is reaſon to believe that of his original bigotry few traces now remained. The real cauſe of his diſmiſſion from the family, we are aſſured, was his pride; and as it muſt have been the pride of parts, it confirms the firſt part of Dr Beddoes's conjecture.

It ſeems he was much diſpleaſed that, when company were

* Dr Beddoes.

were at dinner, he was not defired to remain after the cloth was removed; and yet if he was then only thirteen years of age, it is not eafy to conceive for what purpofe he fhould have ftaid. He could not poffibly know much of the world, or of any thing likely to employ the converfation of country-gentlemen; and we cannot help thinking, that the mafter of the houfe would have treated his guefts with rudenefs had he detained among them a raw boy to liften to every unguarded expreffion which might efcape them over their wine. It would appear, however, that he was not unwilling to give the tutor of his fon an opportunity of difplaying his abilities, when fuch fubjects were introduced as he knew him to have ftudied; for a difpute having arifen, one day after Brown had retired to his own room, concerning the decrees of Providence, he fent to requeft his opinions on that abftrufe fubject. By the meffenger Brown returned a verbal anfwer, that "the decrees of Providence are very unjuft, for having made blockheads lairds."

Mr Cruickfhank had fome time before requefted him to return to the fituation which he had formerly held in the fchool of Dunfe; and we cannot wonder that, immediately after making this infolent anfwer, he found it convenient to comply with his requeft. He was now about fifteen, and he continued in the fchool till the 20th year of his age; during which time, from the conftant habit of teaching the Latin and Greek languages, he acquired a wonderful facility in reading both thefe languages, and in writing the former, though he wrote not with tafte.

About this time it occurred to him that he might turn his claffical acquirements to more account, by becoming a private teacher of languages in Edinburgh. To that city he accordingly repaired, where, while he obtained a livelihood as a teacher, he propofed at the fame time to purfue his theological ftudies at the univerfity. But an accident happened to him here which made him altogether change the plan he had come upon; and the death of his mother, after a refidence of fome time in Edinburgh, abfolved him, as he thought, from the promife which he had made to her of appearing one day in the pulpit. Shortly after an unfuccefsful competition for one of the chairs then vacant in the high-fchool, an application was made to a friend of his for a proper perfon to turn a medical thefis into Latin. Brown was recommended. He was limited to a certain time; within which it appeared fcarce practicable to perform the tafk. He accomplifhed it, however, and in fuch a ftyle of grammatical correctnefs and purity as far exceeded the general run of fuch productions. On this being remarked to him by his friends, he obferved, "that he now knew his ftrength, and was ambitious of riding in his carriage as a phyfician." He therefore determined to apply himfelf with ardour to the ftudy of medicine, to which this accidental circumftance alone directed his attention. Accordingly, at the commencement of the next winter feffion, he addreffed a Latin letter to each of the medical profeffors, and by them was prefented with tickets of admittance to their feveral claffes.

From fuch a favourable beginning, being of a very fanguine difpofition, he conceived the moft flattering expectations of his future fuccefs; and indeed for fome time he feems to have lived in affluent circumftances. His attainments were fo various, and in fuch requeft in Edinburgh, that as a fingle man he could fcarcely fail to gain a competent living; for during the laft five years of his refidence under Mr Cruickfhank, to a thorough acquaintance with ancient hiftory, he had added a very confiderable knowledge of mathematics; in which, among other branches of fcience, he never had any objection to give inftructions. In the acquifition of that variety of knowledge which he poffeffed, he was greatly affifted by a moft tenacious memory; to the retentivenefs of which an old fchool-fellow bears teftimony, by affirming, that "after once reading over the leffon, confifting of two octavo pages in Latin, he would lay afide the book, and prelect the whole over without miftaking a fingle word."

Brown, already in eafy circumftances for an individual, faw, or thought he faw, in the eftablifhment of a boarding-houfe for ftudents a refource which would enable him to maintain a family; and in expectation of realifing this profpect, he married in 1765, the daughter of a refpectable tradefman in Edinburgh. The diftinguifhed attention at that time paid him by Dr Cullen, in whofe family he had become a neceffary perfon, contributed in all probabillity to ftrengthen his hopes that his houfe would be filled with proper boarders through the Doctor's recommendation. His fuccefs in this way for fome time anfwered his moft fanguine expectations; and his circumftances at one period were fo flourifhing, that he is faid to have kept a one-horfe chaife.

It was, perhaps, the greateft misfortune that could have befallen Brown, that he poffeffed, in a high degree, thofe talents which make a man's company fought after by the gay and the diffipated: He was capable of "fetting the table in a roar." We need not therefore wonder at his frequently neglecting more neceffary purfuits to enjoy the conviviality of the numerous friends who courted his company; or that drinking and diffipation became habitual to him. He was as deficient in point of prudence as he excelled in genius. His houfe was filled with refpectable boarders; but as he lived too fplendidly for an income at beft but precarious, he became gradually involved in debt, and his affairs were ftill more embarraffed by the burden of a numerous family. Soon after he began to be involved in thefe difficulties, he fuffered an additional lofs in being deprived of the patronage of Dr Cullen, in confequence of a difagreement that had taken place between them. This enmity, which had for fome time before fecretly fubfifted, probably from mutual jealoufy, was a length excited into an open rupture; firft, by Dr Cullen's not exerting his intereft in procuring for Brown the theoretical chair of medicine, then vacant in confequence either of the death or refignation of Dr Alexander Monro Drummond; and, fecondly, by his rejecting, fome time after, Brown's petition for admittance into the Edinburgh Philofophical Society.

In 1776 Brown was elected prefident of the Medical Society; and the fame honour was again conferred on him in 1780. He was led on, in the gradual manner he himfelf defcribes in his mafterly preface to the *Elementa Medicinæ*, to the difcovery of his new doctrine; which, on dropping all correfpondence with his former friend and benefactor, he now, for the firft time, began to illuftrate in a courfe of public lectures; and in thefe he difplayed equal ingenuity and philofophical profundity.

dity. Much about the time of which we now ſpeak, he publiſhed the firſt edition of the *Elementa Medicinæ;* a work which certainly proves its author to have been a man of uncommon genius and originality of thought. The circumſtances in which this work was compoſed reflect great honour on his abilities. He never retired to his ſtudy; but, totally abſorbed in his own ideas, wrote with the greateſt tranquillity amidſt the noiſe of ten children, occaſionally ſettling their childiſh differences.

In the year 1779, though he had ſtudied medicine ten or twelve years at the univerſity of Edinburgh, he was prevailed upon by his friends to take a degree at St Andrews, where he gave a conſpicuous proof of his facility in Latin compoſition. He wrote a theſis, or inaugural diſſertation, in the tavern while the cloth was laying for dinner; and one of his companions, who was ſinging beſide him, having uttered a falſe note, or ſung out of time, Mr Brown, in the middle of his writing, ſtopped to ſhew him how the ſong ought to be ſung, and then inſtantly proceeded in his theſis.

His family having now become ſo numerous as to render keeping a boarding houſe inconvenient, he had already for ſome time given it up, and depended for ſupport entirely on his practice as a phyſician and his public lectures. At this time, the diſputes between the Cullenians and the Brunonians (as the young men now ſtyled themſelves) were carried on with ſuch acrimony on both ſides, in the different ſocieties, that it was not unuſual for them to terminate in duels; and there exiſts at this day, on the records of the Medical Society, a law which it was thought expedient to enact, by which a member who challenges another for any thing ſaid in public debate incurs the penalty of expulſion.

Obſerving the ſtudents of medicine frequently to ſeek initiation into the myſteries of free-maſonry, Dr Brown thought their youthful curioſity afforded him a chance of proſelytes. In 1784, he inſtituted a meeting of that fraternity, and intitled it *the Lodge of the Roman Eagle.* The buſineſs was conducted in the Latin language, which he ſpoke with the ſame fluency as Scotch; and he diſplayed much ingenuity in turning into Latin all the terms uſed in maſonry.

As the terms on which he lived with his brethren of the faculty were ſuch that he obſtinately avoided meeting them even in conſultation, we may conclude that his own private practice was but limited. His friends affirmed, perhaps without ſufficient proof, that cabals were formed againſt him, and every advantage taken of the errors he was led to commit by his own imprudence. After a long ſeries of ſtruggles, therefore, hoping to meet with that encouragement among the Engliſh of which he had been diſappointed in his own country, he put in practice a plan upon which he had long meditated, and removed in 1786 with part of his family to London. Immediately on his arrival, an incident befel him, which Dr Beddoes ſays he has heard the late Mr Murray, bookſeller in Fleet-ſtreet, relate as a proof of his ſimplicity. The peculiarity of his appearance, as he moved along a (a ſhort ſquare figure, with an air of dignity, in a black ſuit, which heightened the ſcarlet of his cheeks and noſe) fixed the attention of ſome *gentlemen* in the ſtreet. They addreſſed him in the dialect of his country. His heart, heavy as it muſt have been, from the precariouſneſs of his ſituation, and diſtance from his accuſtomed haunts, expanded at theſe agreeable ſounds. A converſation enſued; and the parties, by common conſent, adjourned to a tavern. Here the ſtranger was kindly welcomed to town; and, after the glaſs had circulated for a time, ſomething was propoſed by way of ſober amuſement—a game at cards, or whatever the Doctor might prefer. The Doctor had been too civilly treated to demur; but his purſe was ſcantily furniſhed, and it was neceſſary to quit his new friends in ſearch of a ſupply. Mr Murray was a perſon to whom he had recourſe: the reader will not wonder that his interference ſhould have ſpoiled the adventure.

A London ſharper, of another denomination, afterwards tried to make advantage by the Doctor. This was an ingenious ſpeculator in public medicines. He thought a compoſition of the moſt powerful ſtimulants might have a run, under the title of *Dr Brown's exciting pill;* and, for the privilege of his name, offered him a ſum in hand by no means contemptible, as well as a ſhare of the contingent profits. Poor Brown, needy as he was, ſpurned at the propoſal.

After this period, his life affords little variety of incident. Like Avicenna, his time ſeems to have been ſpent between his literary purſuits and his pleaſures. A ſplendid manner of living, without an income to ſupport it, had become habitual to him: The conſequence was, that, from inability to diſcharge certain debts he had contracted, he was thrown into the king's bench priſon; from which, however, he was, not long afterwards, releaſed by the exertions of a few firm friends, particularly Mr Maddiſon of Charing-croſs, a gentleman univerſally reſpected for his well known benevolence. As a proof of the activity he was ſtill capable of exerting, it will be ſufficient to mention, that he accompliſhed the tranſlation of his *Elementa,* with the addition of the ſupplementary notes, within 23 days, having been informed that a tranſlation of the ſame was about to be publiſhed by another perſon.

Shortly before his death, the ambaſſador of the king of Pruſſia, in the name of his maſter, made Dr Brown an offer of a ſettlement in the court of Berlin; during the negociation of which, he was unexpectedly cut off by an apoplexy early in the morning of the 7th of October 1788, the day ſucceeding that on which he had delivered to a company of thirteen gentlemen the greater part of the introductory lecture to his ſecond courſe. At his death, he was between 52 and 53 years of age. His remains were interred in the church-yard of St James's, Picadilly; and the only monument left behind him to tranſmit his name to poſterity is his own works; which, when perſonal prejudice no longer ſhall prevail againſt their ingenious author, cannot fail to procure him all that deſerved celebrity which they have already, in part, obtained in the different countries of Europe.

In 1787, he publiſhed his "Obſervations," without his name, which he afterwards, however, refers to in the Elements as his own. The "Enquiry," ſaid to be written by Dr Jones, and which was compoſed in as ſhort a time as the generality of men would tranſcribe a work of its extent, we can affirm, from undoubted authority, to be his production.

This ſketch of the life of the unfortunate Dr Brown would be of very little value, if not followed by a view of of his fyftem ; but to give a complete view of that fyftem would far exceed the limits within which, in a work like this, fuch articles muft be confined. We truft, therefore, that our readers will be fatisfied with an abftract ; and as we are neither the partifans nor opponents of the Doctor, and not very partial to any medical *fyftem* whatever, we fhall content ourfelves with inferting, in this place, the view which Dr Beddoes has given of Dr Brown's fundamental propofitions in the valuable obfervations which he has prefixed to his edition of the Elements of Medicine.

" The varied ftructure of organized beings (fays Dr Beddoes), it is the bufinefs of anatomy to explain. Confcioufnefs, affifted by common obfervation, will diftinguifh animated from inanimate bodies with precifion more than fufficient for all the ends of medicine. The caufe of gravitation has been left unexplored by all prudent philofophers ; and Brown, avoiding all ufelefs difquifition concerning the caufe of vitality, confines himfelf to the phenomena which this great moving principle in nature may be obferved to produce. His moft general propofitions are eafy of comprehenfion.

" 1. To every animated being is allotted a certain portion only of the quality or principle on which the phenomena of life depend. This principle is denominated *excitability*.

" 2. The excitability varies in different animals, and in the fame animal at different times. As it is more intenfe, the animal is more vivacious or more fufceptible of the action of exciting powers.

" 3. Exciting powers may be referred to two claffes. 1. External, as heat, food, wine, poifons, contagions, the blood, fecreted fluids, and air. 2. Internal ; as the functions of the body itfelf, mufcular exertion, thinking, emotion and paffion.

" 4. Life is a forced ftate ; if the exciting powers are withdrawn, death enfues as certainly as when the excitability is gone.

" 5. The excitement may be too great, too fmall, or in juft meafure.

" 6. By too great excitement, weaknefs is induced, becaufe the excitability becomes defective ; this is *indirect debility :* when the exciting powers or ftimulants are withheld, weaknefs is induced; and this is *direct debility*. Here the excitability is in excefs.

" 7. Every power that acts on the living frame is ftimulant, or produces excitement by expending excitability. Thus, although a perfon, accuftomed to animal food, may grow weak if he lives upon vegetables, ftill the vegetable diet can only be confidered as producing an effect, the fame in kind with animal, though inferior in degree. Whatever powers, therefore, we imagine, and however they vary from fuch as are habitually applied to produce due excitement, they can only weaken the fyftem by urging it into too much motion, or fuffering it to fink into languor.

" 8. Excitability is feated in the medullary portion of the nerves, and in the mufcles. As foon as it is any where affected, it is immediately affected every where; nor is the excitement ever increafed in a part, while it is generally diminifhed in the fyftem ; in other words, different parts can never be in oppofite ftates of excitement.

" I have already fpoken of an illuftration, drawn up by Mr Chriftie from a familiar operation, to facilitate the conception of Brown's fundamental pofitions. I introduce it here as more likely to anfwer its purpofe than if feparately placed at the end of my preliminary obfervations. ' Suppofe a fire to be made in a grate, filled with a kind of fuel not very combuftible, and which could only be kept burning by means of a machine containing feveral tubes, placed before it, and conftantly pouring ftreams of air into it. Suppofe alfo a pipe to be fixed in the back of the chimney, through which a conftant fupply of frefh fuel was gradually let down into the grate, to repair the wafte occafioned by the flame, kept up by the air machine.

' The grate will reprefent the human frame ; the fuel in it, the matter of life—the excitability of Dr Brown, and the fenforial power of Dr Darwin ; the tube behind, fupplying frefh fuel, will denote the power of all living fyftems, conftantly to regenerate or reproduce excitability ; while the air machine, of feveral tubes, denotes the various ftimuli applied to the excitability of the body ; and the flame drawn forth in confequence of that application reprefents life, the product of the exciting powers acting upon the excitability.

' As Dr Brown has defined life to be *a forced ftate*, it is fitly reprefented by a flame forcibly drawn forth from fuel little difpofed to combuftion, by the conftant application of ftreams of air poured into it from the different tubes of a machine. If fome of thefe tubes are fuppofed to convey pure or dephlogifticated air, they will denote the higheft clafs of exciting powers, opium, mufk, camphor, fpirits, wine, tobacco, &c. the diffufible ftimuli of Dr Brown, which bring forth for a time a greater quantity of life than ufual, as the blowing in of pure air into a fire will temporarily draw forth an uncommon quantity of flame. If others of the tubes be fuppofed to convey common or atmofpheric air, they will reprefent the ordinary exciting powers, or ftimuli, applied to the human frame, fuch as heat, light, air, food, drink, &c. while fuch as convey impure and inflammable air may be ufed to denote what have formerly been termed fedative powers, fuch as poifons, contagious miafmata, foul air, &c.

' The reader will now probably be at no lofs to underftand the feeming paradox of the Brunonian fyftem ; that food, drink, and all the powers applied to the body, though they fupport life, yet confume it ; for he will fee, that the application of thefe powers, though it brings forth life, yet at the fame time it waftes the excitability or matter of life, juft as the air blown into the fire brings forth more flame, but waftes the fuel or matter of fire. This is conformable to the common faying, " the more a fpark is blown, the brighter it burns, and the fooner it is fpent." A Roman poet has given us, without intending it, an excellent illuftration of the Brunonian fyftem, when he fays,

" *Balnea, vina, Venus, confumunt corpora noftra ;*
" *Sed vitam faciunt balnea, vina, Venus.*

" Wine, warmth, and love, our vigour drain ;
" Yet wine, warmth, love, our life fuftain."

Or to tranflate it more literally,

" Baths, women, wine, exhauft our frame ;
" But life itfelf is drawn from them."

' Equally eafy will it be to illuftrate the two kinds of of debility, termed *direct* and *indirect*, which, according to Brown are the cause of all diseases. If the quantity of stimulus, or exciting power, is proportioned to the quantity of excitability, that is, if no more excitement is drawn forth than is equal to the quantity of excitability produced, the human frame will be in a state of health, just as the fire will be in a vigorous state when no more air is blown in than is sufficient to consume the fresh supply of fuel constantly poured down by the tube behind. If a sufficient quantity of stimulus is not applied, or air not blown in, the excitability in the man, and the fuel in the fire, will accumulate, producing direct debility; for the man will become weak, and the fire low. Carried to a certain degree, they will occasion death to the first, and extinction to the last. If, again, an over proportion of stimulus be applied, or too much air blown in, the excitability will soon be wasted, and the matter of fuel almost spent. Hence will arise indirect debility, producing the same weakness in the man, and lowness in the fire, as before, and equally terminating, when carried to a certain degree, in death and extinction.

'As all the diseases of the body, according to Dr Brown, are occasioned by direct or indirect debility, in consequence of too much or too little stimuli, so all the defects of the fire must arise from direct or indirect lowness, in consequence of too much or too little air blown into it. As Brown taught that one debility was never to be cured by another, but both by the more judicious application of stimuli, so will be found the case in treating the defects of the fire. If the fire has become low, or the man weak, by the want of the needful quantity of stimulus, more must be applied, but very gently at first, and increased by degrees, lest a strong stimulus applied to the accumulated excitability should produce death; as in the case of a limb benumbed with cold (that is, weakened by the accumulation of its excitability in consequence of the abstraction of the usual stimulus of heat), and suddenly held to the fire, which we know from experience is in danger of mortification, or as in the case of the fire becoming very low by the accumulation of the matter of fuel, when the feeble flame, assailed by a sudden and strong blast of air, would be overpowered and put out, instead of being nourished and increased. Again, if the man or the fire have been rendered indirectly weak, by the application of too much stimulus, we are not suddenly to withdraw the whole, or even a great quantity of the exciting powers or air, for then the weakened life and diminished flame might sink entirely; but we are by little and little to diminish the overplus of stimulus, so as to enable the excitability, or matter of fuel, gradually to recover its proper proportion. Thus a man who has injured his constitution by the abuse of spirituous liquors is not suddenly to be reduced to water alone, as is the practice of some physicians, but he is to be treated as the judicious Dr Pitcairn of Edinburgh is said to have treated a Highland chieftain, who applied to him for advice in this situation. The Doctor gave him no medicines, and only exacted a promise of him, that he would every day put in as much wax into the wooden *queich*, out of which he drank his whisky, as would receive the impression of his arms. The wax thus gradually accumulating, diminished daily the quantity of the whisky, till the whole *queich* was filled with wax; and the chieftain was thus gradually, and without injury to his constitution, cured of the habit of drinking spirits.

'These analogies might be pursued farther; but my object is solely to furnish some general ideas, to prepare the reader for entering more easily into the Brunonian theory, which I think he will be enabled to do after perusing what I have said. The great excellence of that theory, as applied, not only to the practice of physic, but to the general conduct of the health, is, that it impresses on the mind a sense of the impropriety and danger of going from one extreme to another. The human frame is capable of enduring great varieties, if time be given it, to accommodate itself to different states. All the mischief is done in the transition from one state to another. In a state of low excitement we are not rashly to induce a state of high excitement, nor when elevated to the latter, are we suddenly to descend to the former, but step by step, and as one who from the top of a high tower descends to the ground. From hasty and violent changes, the human frame always suffers; its particles are torn asunder, its organs injured, the vital principle impaired, and disease, often death, is the inevitable consequence.

'I have only to add, that though in this illustration of the Brunonian system (written several years ago), I have spoken of a tube constantly pouring in fresh fuel, because I could not otherwise convey to the reader a familiar idea of the power possessed by all living systems, to renew their excitability when exhausted; yet it may be proper to inform the student, that Dr Brown supposed every living system to have received at the beginning its determinate portion of excitability; and, therefore, although he spoke of the exhaustion, augmentation, and even renewal of excitability, I do not think it was his intention to induce his pupils to think of it as a kind of fluid substance existing in the animal, and subject to the law by which such substances are governed. According to him, excitability was an unknown *somewhat*, subject to peculiar laws of its own, and whose different states we were obliged to describe (though inaccurately) by terms borrowed from the qualities of material substances.'

"The Brunonian system has frequently been charged with promoting intemperance. The objection is serious; but the view already given of its principles shews it to be groundless. No writer had insisted so much upon the dependence of life on external causes, or so strongly stated the inevitable consequences of excess. And there are no means of promoting morality upon which we can rely, except the knowledge of the true relations between man and other beings or bodies. For by this knowledge we are directly led to shun what is hurtful, and pursue what is salutary: and in what else does moral conduct, as far it regards the individual, consist? It may be said that the author's life disproves the justness of this representation: his life, however, only shews the superior power of other causes, and of bad habits in particular; and I am ready to acknowledge the little efficacy of instruction when bad habits are formed. Its great use consists in preventing their formation; for which reason popular instruction in medicine would contribute more to the happiness of the human species, than the complete knowledge of every thing which is attempted to be taught in education,

tion, as it is conducted at prefent. But though the principles of the fyftem in queftion did not correct the propenfities of its inventor, it does not follow that they tend to produce the fame propenfities in others."

BROWNSVILLE, or *Redftone Old fort*, is a flourifhing poft-town in Fayette co. Pennfylvania; on the S. eaftern bank of Monongahela River; between Dunlap and Redftone creeks; and next to Pittfburg is the moft confiderable town in the weftern parts of the ftate. The town is regularly laid out, contains about 100 houfes, an Epifcopalian, and Roman Catholic church, a brewery and diftillery. It is connected with Bridgeport, a fmall village on the oppofite fide of Dunlap creek, by a bridge 260 feet long. Within a few miles of the town are 4 Friends' meeting-houfes, 24 grift, faw, oil, and fulling mills. The trade and emigration to Kentucky, employ boat builders here very profitably; above 100 boats of 20 tons each, are built annually. Byrd's Fort formerly ftood here, on the S. fide of the mouth of Redftone Creek, in N. lat. 39. 58. W. long. 81 12½; 37 miles foutherly from Pittfburg; 13 S. by E. of Wafhington, and 341 W. of Philadelphia.—*Morse*.

BRUCE (James, Efq; F. R. S.), the celebrated Abyffinian traveller, was born, 1730, at Kinnaird houfe, in the parifh of Larbert and county of Stirling. His defcent by both parents was ancient and honourable; and of that defcent he was, perhaps, too proud. His grandfather was —— Hay, Efq; of Woodcockdale, in the county of Linlithgow, who, marrying Mifs Bruce, the heirefs of Kinnaird, gave the name of *Bruce* to all his defcendants.

Perhaps this change of name may have taken place in obedience to the deed by which the eftate of Kinnaird was fettled on Mrs Hay's children; but it is a change which, in a country like Scotland, where antiquity of defcent is highly valued, any man would voluntarily have adopted, who had married the heirefs of fuch a family. The Bruces of Kinnaird had been in poffeffion of that eftate for three centuries: they were defcended from a younger fon of Robert de Bruce, the competitor with Baliol for the crown of Scotland. It would readily occur, that the knowledge of fuch a defcent would be beft preferved by continuing the name of their great anceftor; and we have reafon to believe, that the fubject of this memoir was not much delighted when put in mind, as he frequently was, that, though the heir of the line, he was not the *male* heir of that branch of the illuftrious family.

As he was allied to royalty by his father and grandmother, through his mother he was related to fome of the moft refpectable families in the kingdom. She was the daughter of James Graham, Efq; of Airth, dean of the faculty of advocates, and judge of the high court of admiralty in Scotland, by Marion daughter of James Hamilton, Efq; of Pencaitland; and to a man of our traveller's turn of mind, there can be no doubt but that it muft have afforded much fatisfaction to think, that no family ranks higher in Scotland than thofe of Bruce, Graham, and Hamilton. In him, however, it was weaknefs to be proud, if indeed he was proud, of family; for the talents beftowed upon him by nature, or to fpeak more properly, by nature's God, would have made him great though he had been born on a dunghill. He would indeed have been, in all probability, much greater than he was, had he not been in poffeffion of the phantom of birth to gratify much of his ambition; for the facility with which he maftered every ftudy in which he engaged, would have carried him quickly to the top of the moft honourable profeffion.

Mr Bruce was inftructed in grammatical learning at the fchool of Harrow on the Hill, in the county of Middlefex, where he gave the moft unequivocal proofs of genius, and acquired a very confiderable knowledge of the Greek and Latin languages. It was cuftomary with him to perform, not only his own exercifes, but alfo the exercifes of fuch of his companions as were not equal to the tafk themfelves. Among thefe was his maternal uncle, who was frequently indebted to his affiftance, and, on one occafion, produced a copy of verfes of his compofition, which excited, not only the applaufe, but the admiration of their mafter. Mr Graham, who was but a few months older than Mr Bruce, had, for fome tranfgreffion (we know not what), been punifhed, as boys in the great fchools in England are often punifhed, by having a tafk fet him, which he foon found himfelf unable to perform. His nephew defired him to be under no uneafinefs, promifing to furnifh him with the verfes before the time at which they were to be given in. He was as good as his word; but the mafter of the fchool foon difcovering that they were not the performance of Mr Graham, exclaimed, that the author of thefe verfes, whoever he was, might apply to himfelf the words of Horace,

——*Sublimi feriam fidera vertice.*

While Mr Bruce was at Harrow, and for a year or two after he had left it, he was of a very delicate frame, and appeared to his friends to be threatened with a confumption. The truth is, that he was uncommonly tall for his age, and felt all the feeblenefs of joints and other bodily weakneffes to which overgrown boys are generally fubject. His father intended him for the profeffion of the law; and, upon his return from Harrow, he was entered into the univerfity of Edinburgh, where he went through a regular courfe of ftudy to fit him for being inrolled in the body of advocates; but for fome reafon, which we do not perfectly know, he relinquifhed the ftudy of law for the purfuits of trade; and, going to London, entered into partnerfhip with a wine-merchant of the name of Allen, whofe daughter he married.

That lady falling into a bad ftate of health, Mr Bruce took her abroad, in hopes that travelling would be attended with beneficial effects; but in thefe he was difappointed, as fhe died within a year after her marriage. He was induced, in order to difpel his grief, to continue his travels; during which his father dying (at Edinburgh, 4th May 1758), the inheritance of his anceftors devolved upon him, and he returned to Britain. Some of his fubfequent tranfactions fhall now be related in his own words.

"Every one will remember that period, fo glorious to Britain, the latter end of the miniftry of the late earl of Chatham. I was then returned from a tour through the greateft part of Europe, particularly thro' the whole of Spain and Portugal, between whom there was then the appearance of an approaching war.

"I was about to retire to a fmall patrimony I had received from my anceftors, in order to embrace a life of ftudy and reflection, nothing more active appearing within my power, when chance threw me unexpectedly into a very fhort and very defultory converfation with Lord Chatham.

" It was a few days after this, that Mr Wood, then under fecretary of ftate, my zealous and fincere friend, informed me that Lord Chatham intended to employ me upon a particular fervice; that, however, I might go down for a few weeks to my own country to fettle my affairs, but, by all means, to be ready upon a call. Nothing could be more flattering to me than fuch an offer, when fo young; to be thought worthy by Lord Chatham of any employment, was doubly a preference. No time was loft on my fide; but juft after receiving orders to return to London, his lordfhip had gone to Bath, and refigned his office.

" This difappointment, which was the more fenfible to me that it was the firft I had met with in public life, was promifed to be made up to me by Lord Egremont and Mr George Grenville. The former had been long my friend; but unhappily he was then far gone in a lethargic indifpofition, which threatened, and did very foon put a period to his exiftence. With Lord Egremont's death my expectations vanifhed. Further particulars are unneceffary; but I hope that, at leaft in part, they remain in that breaft where they naturally ought to be, and where I fhall ever think, not to be long forgotten, is to be rewarded.

" Seven or eight months were paffed in an expenfive and fruitlefs attendance in London, when Lord Halifax was pleafed, not only to propofe, but to plan for me a journey of confiderable importance, and which was to take up feveral years. His lordfhip faid, that nothing could be more ignoble than, at fuch a time of life, at the height of my reading, health, and activity, I fhould, as it were, turn peafant, and voluntarily bury myfelf in obfcurity and idlenefs; that though war was now drawing faft to an end, full as honourable a competition remained among men of fpirit, which fhould acquit themfelves beft in the dangerous line of ufeful adventure and difcovery.

" He obferved, that the coaft of Barbary, which might be faid to be juft at our door, was yet but partially explored by Dr Shaw, who had only illuftrated (very judicioufly indeed) the geographical labours of Sanfon; that neither Dr Shaw nor Sanfon had been, or pretended to be, capable of giving the public any detail of the large and magnificent remains of ruined architecture, which they both vouch to have feen in great quantities, and of exquifite elegance and perfection, all over the country. Such had not been their ftudy, yet fuch was really the tafte that was required in the prefent times. He wifhed, therefore, that I fhould be the firft, in the reign juft now beginning, to fet an example of making large additions to the royal collection; and he pledged himfelf to be my fupport and patron, and to make good to me, upon this additional merit, the promifes which had been held forth to me by former minifters for other fervices.

" The difcovery of the fource of the Nile was alfo a fubject of thefe converfations, but it was always mentioned to me with a kind of diffidence, as if to be expected from a more experienced traveller. Whether this was but another way of exciting me to the attempt I fhall not fay; but my heart, in that inftant, did me juftice to fuggeft, that this too was either to be atchieved by me, or to remain as it had done for thefe laft 2000 years, a defiance to all travellers, and an opprobrium to geography.

" Fortune feemed to enter into this fcheme. At the very inftant, Mr Afpinwall, very cruelly and ignominioufly treated by the dey of Algiers, had refigned his confulfhip, and Mr Ford a merchant, formerly the dey's acquaintance, was named in his place. Mr Ford was appointed, and, dying a few days after, the confulfhip became vacant. Lord Halifax preffed me to accept of this as containing all forts of conveniences for making the propofed expedition.

" This favourable event finally determined me. I had all my life applied unweariedly, perhaps with more love than talent, to drawing, the practice of mathematics, and efpecially that part neceffary to aftronomy. The tranfit of Venus was at hand. It was certainly known that it would be vifible once at Algiers, and there was great reafon to expect it might be twice. I had furnifhed myfelf with a large apparatus of inftruments, the completeft of their kind, for the obfervation. In the choice of thefe, I had been affifted by my friend Admiral Campbell, and Mr Ruffel, fecretary to the Turkey Company: every other neceffary had been provided in proportion. It was a pleafure now to know that it was not from a rock or a wood, but from my own houfe at Algiers, I could deliberately take meafures to place myfelf in the lift of men of fcience of all nations, who were then preparing for the fame fcientific purpofe.

" Thus prepared, I fet out for Italy, through France; and though it was in time of war, and fome ftrong objections had been made to particular paffports, folicited by our government from the French fecretary of ftate, Monfieur de Choifeul moft obligingly waved all fuch exceptions with regard to me, and moft politely affured me, in a letter accompanying my paffport, that thofe difficulties did not in any fhape regard me, but that I was perfectly at liberty to pafs through, or remain in, France, with thofe that accompanied me, without limiting their number, as fhort or as long a time as fhould be agreeable to me.

" On my arrival at Rome, I received orders to proceed to Naples, there to await his majefty's further commands. Sir Charles Saunders, then with a fleet before Cadiz, had orders to vifit Malta before he returned to England. It was faid that the grand mafter of that order had behaved fo improperly to Mr Harvey (afterwards Lord Briftol) in the beginning of the war, and fo partially and unjuftly between the two nations in the courfe of it, that an explanation on our part was become neceffary. The grand mafter no fooner heard of my arrival at Naples, than, gueffing the errand, he fent off Chevalier Mazzini to London, where he at once made his peace and his compliments to his majefty upon his acceffion to the throne.

" Nothing remained now but to take poffeffion of my confulfhip. I returned, without lofs of time, to Rome, and from thence to Leghorn, where having embarked on board the Montreal man of war, I proceeded to Algiers.

" While at Naples, I received from flaves, redeemed from the province of Conftantine, accounts of magnificent ruins they had feen while traverfing that country with

with their mafter the Bey. I faw the abfolute neceffity there was for affiftance, without which it was impoffible for any one man, however diligent and qualified, to do any thing but bewilder himfelf. All my endeavours, however, had hitherto been unfuccefsful to perfuade any Italian to put himfelf wilfully into the hands of a people conftantly looked upon by them in no better light than pirates. At laft Mr Lumifden, by accident, heard of a young man who was then ftudying architecture at Rome, a native of Bologna, whofe name was Luigi Balugani. I can appeal to Mr Lumifden as to the extent of this perfon's practice and knowledge, and that he knew very little when firft fent to me. In the twenty months which he ftaid with me at Algiers, by affiduous application to proper fubjects under my inftruction, he became a very confiderable help to me, and was the only one that ever I made ufe of, or that attended me for a moment, or ever touched one reprefentation of architecture in any part of my journey."

Our traveller, when in Spain, had endeavoured to find accefs to that immenfe collection of Arabic manufcripts which were perifhing in the duft of the efcurial; but in vain. "All my fuccefs (fays he) in Europe terminated in the acquifition of thofe few printed Arabic books that I had found in Holland; and thefe were rather biographers than general hiftorians, and contained little in point of general information. The ftudy of thefe, however, and of Maracci's Koran, had made me a very tolerable Arab; a great field was opening before me in Africa to complete a collection of manufcripts, an opportunity which I did not neglect.

"After a year fpent at Algiers, conftant converfation with the natives while abroad, and with my manufcripts within doors, had qualified me to appear in any part of the continent without the help of an interpreter. Ludolf had affured his readers, that the knowledge of any oriental language would foon enable them to acquire the Ethiopic; and I needed only the fame number of books to have made my knowledge of that language go hand in hand with my attainments in the Arabic. My immediate profpect of fetting out on my journey to the inland parts of Africa, had made me double my diligence; night and day there was no relaxation from thefe ftudies, although the acquiring any fingle language had never been with me either an object of time or difficulty."

At Algiers Mr Bruce was detained longer than he expected, in confequence of a difpute with the Dey concerning Mediterranean paffes. This being adjufted, he proceeded to Mahon, and from Mahon to Carthage. He next vifited Tunis and Tripoli, and travelled over the interior parts of thefe ftates. At Bengazi, a fmall town on the Mediterranean, he fuffered fhipwreck, and with extreme difficulty faved his life, though with the lofs of all his baggage. He afterwards failed to the ifles of Rhodes and Cyprus, and proceeding to Afia Minor, travelled through a confiderable part of Syria and Paleftine, vifiting Haffia, Latikea, Aleppo, and Tripoli; near which laft city he was again in imminent danger of perifhing in a river. The ruins of Palmyra and Baalbec were next carefully furveyed and fketched by him; and his drawings of thefe places are depofited in the king's library at Kew; "the moft magnificent prefent in that line," to ufe his own words, "ever made by a fubject to his fovereign."

It is much to be regretted that Mr Bruce publifhed no particular account of thefe various journeys; from the nature of the places vifited, and the abilities of the man, much curious and ufeful information might have been expected. Some manufcript accounts of different parts of them are faid to have been left by him, but whether in fuch a ftate as to be fit for publication, we have not learned.

In thefe various travels fome years were paffed; and Mr Bruce now prepared for the grand expedition, the accomplifhment of which had ever been neareft his heart, the difcovery of the fources of the Nile. In the profecution of that dangerous object, he left Sidon on the 15th of June 1768, and arrived at Alexandria on the 20th of that month. He proceeded from thence to Cairo, where he continued to the 12th of December following, when he embarked on the Nile; and in a very extraordinary boat, called a *canja*, of which he fays the main-fail yard was about 200 feet in length, he failed up that river as far as Syene, vifiting in the courfe of his voyage the ruins of Thebes, and the place where Memphis once ftood, now known by the name of *Metrahenny*. Leaving Kenne on the Nile, 16th February 1769, he croffed the defert of the Thebaid to Coffeir on the Red Sea, and arrived at Jidda on the 3d of May. In Arabia Felix he remained, not without making feveral excurfions, till the 3d of September, when he failed from Loheia, and arrived on the 19th at Mafuah, where he was detained near two months by the treachery and avarice of the Naybe of that place. It was not till the 15th of November that he was allowed to quit Arkeeko, near Mafua; and he arrived on the 15th of February 1770 at Gondar, the capital of Abyffinia, where he ingratiated himfelf with the moft confiderable perfons of both fexes belonging to the court. This he accomplifhed by being a phyfician in the city, a foldier in the field, a courtier everywhere, demeaning himfelf as confcious that he was not unworthy of being a companion to the firft of their nobility, and the king's gueft, which is there a character, as it was with eaftern nations of old, to which a certain fort of confideration is due. "To this I may add (fays he), that, being in the prime of life, of no ungracious figure, having an accidental knack, which is not a trifle, of putting on the drefs, and fpeaking the language eafily and gracefully, I cultivated, with the utmoft affiduity, the friendfhip of the fair fex, by the moft modeft and refpectful diftant attendance and obfequioufnefs in public, abating juft as much of that in private as fuited their humours and inclination;" and jealoufy being a paffion unknown in Abyffinia, he thus acquired from the ladies great fupport at court.

Several months were employed in attendance on the king, and in an unfuccefsful expedition round the lake of Dambea. Towards the end of October Mr Bruce fet out for the fources of the Nile; at which long defired fpot he arrived on the 14th of November; and his feelings on the accomplifhment of his wifhes cannot better be expreffed than in his own words:

"It is eafier to guefs than to defcribe the fituation of my mind at that moment; ftanding in that fpot which had baffled the genius, induftry, and inquiry, of ancients and moderns for the courfe of near 3000 years. Kings had attempted this difcovery at the head of armies, and each expedition was diftinguifhed from the laſt only by the difference of the numbers which had periſhed, and agreed alone in the diſappointment which had uniformly, and without exception, followed them all. Fame, riches, and honour, had been held out for a ſeries of ages to every individual of thoſe myriads thoſe princes commanded, without having produced one man capable of gratifying the curioſity of his ſovereign, or wiping off this ſtain upon the enterpriſe and abilities of mankind, or adding this deſideratum for the encouragement of geography. Though a mere private Briton, I triumphed here in my own mind over kings and their armies; and every compariſon was leading nearer and nearer to the preſumption, when the place itſelf where I ſtood, the object of my vain glory, ſuggeſted what depreſſed my ſhort-lived triumphs."

If theſe triumphs were ſhort-lived, they were equally ill-founded; for if the ſource of the Nile was ſeen by Mr Bruce, there can be no doubt of its having been likewiſe ſeen by the Portugueſe jeſuits. Of this we have elſewhere brought forward ſufficient proof; and the candid reader, who ſhall take the trouble to compare the extract printed at the bottom of this page (A), with our traveller's account of theſe coy fountains, as it ſtands in his own book or in our article Nile *(Encycl.)*, will be convinced that it was ridiculous in Mr Bruce, and is equally ridiculous in his friends, to pretend that he *diſcovered* what had baffled the genius of inquiry for the courſe of near 3000 years.

It was not, however, the conſciouſneſs of having been anticipated by the jeſuits (for theſe he without ceremony calls a ſet of liars), but the proſpect of danger to be encountered on his return to Europe, that caſt ſuch a damp on his preſent enjoyment. " I was but a few minutes (ſays he) arrived at the ſource of the Nile, through numberleſs dangers and ſufferings, the leaſt of which would have overwhelmed me, but for the continual goodneſs and protection of Providence; I was, however, but then half through my journey, and all thoſe dangers which I had already paſſed awaited me again on my return. I found a deſpondency gaining ground faſt upon me, which blaſted the crown of laurels I had too raſhly woven for myſelf."

When he returned to reſt the night of that diſcovery, repoſe was ſought for in vain. " Melancholy reflections upon my preſent ſtate, the doubtfulneſs of my return in ſafety, were I permitted to make the attempt, and the fears that even this would be refuſed, according to the rule obſerved in Abyſſinia with all travellers who have once entered the kingdom; the conſciouſneſs of the pain that I was then occaſioning to many worthy individuals, expecting daily that information concerning my ſituation which it was not in my power to give them; ſome other thoughts perhaps, ſtill nearer the heart than thoſe, crowded upon my mind, and forbade all approach of ſleep.

" I was, at that very moment, in poſſeſſion of what had for many years been the principal object of my ambition and wiſhes; indifference which, from the uſual infirmity of human nature, follows, at leaſt for a time, complete enjoyment, had taken place of it. The marſh, and the fountains, upon compariſon with the riſe of many of our rivers, became now a trifling object in my ſight. I remembered that magnificent ſcene in my own native country, where the Tweed, Clyde, and Annan, riſe in one hill; three rivers I now thought not inferior to the Nile in beauty, preferable to it in the cultivation of thoſe countries through which they flow; ſuperior, vaſtly ſuperior to it in the virtues and qualities of the inhabitants, and in the beauty of its flocks, crowding its paſtures in peace, without fear of violence from man or beaſt. I had ſeen the riſe of the Rhine and Rhone, and the more magnificent ſources of the Soane; I began, in my ſorrow, to treat the inquiry about the ſource of the Nile as a violent effort of a diſtempered fancy,

> ' What's Hecuba to him, or he to Hecuba,
> ' That he ſhould weep for her?'

Grief and deſpondency now rolling upon me like a torrent, relaxed, not refreſhed, by unquiet and imperfect ſleep, I ſtarted from my bed in the utmoſt agony; I went to the door of my tent, every thing was ſtill; the Nile, at whoſe head I ſtood, was not capable either to promote or to interrupt my ſlumbers, but the coolneſs and ſerenity of the night braced my nerves, and chaſed away thoſe phantoms that while in bed had oppreſſed and tormented me.

" It was true that numerous dangers, hardſhips, and ſorrows, had beſet me through this half of my excurſion; but it was ſtill as true, that another Guide, more powerful than my own courage, health, or underſtanding, if any of them can be called man's own, had uniformly

---

(A) " In the eaſtern part of this kingdom, on the declivity of a mountain, whoſe deſcent is ſo eaſy that it ſeems a beautiful plain, is that ſource of the Nile which has been ſought after at ſo much expence of labour, and about which ſuch variety of conjectures hath been formed without ſucceſs. This ſpring, or rather theſe two ſprings, are two holes, each about two feet diameter, a ſtone's caſt diſtant from each other. The one is about five feet and an half in depth, at leaſt we could not get our plummet farther, perhaps becauſe it was ſtopped by roots, for the whole place is full of trees: of the other, which is ſomewhat leſs, with a line of ten feet we could find no bottom, and were aſſured by the inhabitants that none ever had been found. It is believed here that theſe ſprings are the vents of a great ſubterraneous lake; and they have this circumſtance to favour their opinion, that the ground is always moiſt, and ſo ſoft that the water boils up under foot as one walks upon it. Such is the ground round about theſe fountains. At a little diſtance to the ſouth is a village named *Guix* (the *Geeſh* of Mr Bruce), through which the way lies to the top of the mountain, whence the traveller diſcovers a vaſt extent of land, which appears like a deep valley, though the mountain riſes ſo imperceptibly, that thoſe who go up or down it are ſcarce ſenſible of any declivity."—*Johnſon's Tranſlation of Father Lobo's Voyage to Abyſſinia*, Chap. X.

The only difference between Lobo's and Bruce's account of theſe fountains worthy of notice is, that the former found but *two*, while the latter found *three* holes; but Bruce ſays expreſsly, that the holes are partly artificial; and Lobo's deſcription of them indicates the ſame thing. It is therefore not improbable that there may now be four or five holes.

formly protected me in all that tedious half. I found my confidence not abated, that still the same Guide was able to conduct me to my wished-for home. I immediately resumed my former fortitude, considered the Nile as indeed no more than rising from springs as all other rivers do, but widely differing in this, that it was the palm for 3000 years held out to all the nations of the world as a *detur dignissimo*, which in my cool hours I had thought was worth the attempting at the risk of my life, which I had long either resolved to lose, or lay this discovery a trophy in which I could have no competitor, for the honour of my country, at the feet of my sovereign, whose servant I was."

How unworthy is this ranting reflection of the greatness of mind which Mr Bruce on other occasions unquestionably displayed! Had he indeed been the first European who discovered those pitiful holes from which the Nile is said to flow, his merit would not have consisted in travelling from Gondar to the village Geesh, and viewing the fountains which are at that village the objects of idolatrous adoration, but in the address with which he contrived to make himself the favourite of all the factions which agitated a barbarous and almost inhuman nation. In managing those factions, he was indeed great; but he seems to have valued himself more upon looking at three springs, of which it is far from being certain that they are the sources of the Nile (see NILE, *Encycl.*), and of which two had certainly been examined more than a century before he was born, by different missionaries from the kingdom of Portugal! This, however, he calls the object of his wishes; and having now accomplished it, he bent his thoughts on his return to his native country.

He arrived at Gondar on the 19th November 1770; but found, after repeated solicitations, that it was by no means an easy task to obtain permission to quit Abyssinia. A civil war in the mean time breaking out (no uncommon occurrence in that barbarous country), several engagements took place between the king's forces and the troops of the rebels, particularly three actions at a place called Serbraxos on the 19th, 20th, and 23d of May 1771. In each of them Mr Bruce acted a considerable part, and for his valiant conduct in the second received, as a reward from the king, a chain of gold, of 184 links, each link weighing $3\frac{1}{11}$ dwts. or somewhat more than $2\frac{1}{2}$ lbs. troy in all. At Gondar, after these engagements, he again preferred the most earnest intreaties to be allowed to return home, intreaties which were long resisted; but his health at last giving way, from the anxiety of his mind, the king consented to his departure, on condition of his engaging by oath (B) to return to him in the event of his recovery, with as many of his kindred as he could engage to accompany him.

After a residence of nearly two years in that wretched country, Mr Bruce left Gondar on the 16th of December 1771, taking the dangerous way of the desart of Nubia, in place of the more easy road of Masuah, by which he entered Abyssinia. He was induced to take this route from his knowledge and former experience of the cruel and savage temper of the Naybe of Masuah. Arriving at Teawa the 21st March 1772, he had the misfortune to find the Shekh Fidele of Atbara, the counterpart of the Naybe of Masuah, in every bad quality; by his intrepidity and prudence, however, and by making good use of his foreknowledge of an eclipse of the moon, which happened on the 17th of April, he was permitted to depart next day, and he arrived at Sennaar on the 29th of the same month.

Mr Bruce was detained upwards of four months at that miserable and inhospitable place; the inhabitants of which he describes in these expressive words: "War and treason seem to be the only employment of these horrid people, whom heaven has separated by almost impassable deserts from the rest of mankind, confining them to an accursed spot, seemingly to give them an earnest in time of the only other worse which he has reserved to them for an eternal hereafter." This delay was occasioned by the villany of those who had undertaken to supply him with money; but at last, by disposing of 178 links of his gold chain, the well-earned trophy of Serbraxos, he was enabled to make preparation for his dangerous journey though the deserts of Nubia.

He left Sennaar on the 5th of September, and arrived on the 3d of October at Chendi, which he quitted on the 20th, and travelled through the desert of Gooz, to which village he came on the 26th of October. On the 9th of November he left Gooz, and entered upon the most dreadful and dangerous part of his journey; the perils attending which he has related with a power of pencil not unworthy of the greatest masters. All his camels having perished, Mr Bruce was under the necessity of abandoning his baggage in the desert, and with the greatest difficulty reached Assouan upon the Nile on the 29th of November.

After some days rest, having procured fresh camels, he returned into the desert, and recovered his baggage, among which is particularly to be remarked a quadrant (of three feet radius) supplied by Louis XV. from the Military Academy at Marseilles; by means of which noble instrument, now deposited in the museum at Kinnaird, Mr Bruce was enabled with precision and accuracy to fix the relative situations of the several remote places he visited.

On the 10th of January 1773, after more than four years absence, he arrived at Cairo, where, by his manly and generous behaviour, he so won the heart of Mahomet Bey, that he obtained a firman, permitting the commanders of English vessels belonging to Bombay and Bengal to bring their ships and merchandise to Suez, a place far preferable in all respects to Jidda, to which they were formerly confined. Of this permission, which no European nation could ever before acquire, many English vessels have since availed themselves; and it has proved peculiarly useful both in public and private dispatches. Such was the worthy conclusion of his memorable journey through the desert; a journey which, after many hardships and dangers, terminated in obtaining this great national benefit.

At

(B) With regard to this oath, Mr Bruce says, that he hopes the difficulty of performing it extinguished the sin of breaking it; and that, at any rate, it being merely personal, his engagement to return ceased with the death of the king, of which he received intelligence during his stay at Sennaar.

Bruce.

At Cairo Mr Bruce's earthly career had nearly been concluded by a diforder in his leg, occafioned by a worm in the flefh. This accident kept him five weeks in extreme agony, and his health was not re-eftablifhed till a twelvemonth afterwards, at the baths of Porretta in Italy. On his return to Europe, Mr Bruce was received with all the admiration due to fo exalted a character. After paffing fome confiderable time in France, particularly at Montbard, with his friend the Comte de Buffon, by whom he was received with much hofpitality, and is mentioned with great applaufe, he at laft revifited his native country, from which he had been upwards of twelve years abfent.

It was now expected that he would take the earlieft opportunity of giving to the world a narrative of his travels, in which the public curiofity could not but be deeply interefted. But feveral circumftances contributed to delay the publication; and what thefe were will be beft related in his own words:

"My friends at home gave me up for dead; and as my death muft have happened in circumftances difficult to have been proved, my property became as it were a *hæreditas jacens*, without an owner, abandoned in common to thofe whofe original title extended no further than temporary poffeffion.

"A number of law-fuits were the inevitable confequences of this upon my return. To thefe difagreeable avocations, which took up much time, were added others ftill more unfortunate. The relentlefs ague, caught at Bengazi, maintained its ground, at times, for a fpace of more than 16 years, though every remedy had been ufed, but in vain; and what was worft of all, a lingering diftemper had ferioufly threatened the life of a moft near relation (his fecond wife), which, after nine years conftant alarm, where every duty bound me to attention and attendance, conducted her at laft, in very early life, to her grave."

Amidft the anxiety and the diftrefs thus occafioned, Mr Bruce was by no means neglectful of his private affairs. He confiderably improved his landed property, inclofing and cultivating the wafte grounds, and he highly embellifhed his paternal feat, making many additions to the houfe, one in particular of a noble mufeum, filled with the moft precious ftores of oriental literature, large collections of drawings made, and curious articles obtained, during his far extended peregrinations. An excellent ftratum of coal at Kinnaird drew much of his attention; he erected fteam engines of the moft approved conftruction; and placed his coalliery on fuch a footing that, at the period of his deceafe, it produced about 2000l. a-year.

The termination of fome law-fuits, and of other bufinefs, which had occupied much of his time, having at length afforded leifure to Mr Bruce to put his materials in order, his greatly defired and long expected work made its appearance in 1790, in five large quarto volumes, embellifhed with plates and charts. It is unneceffary, and might be tedious, to enter at prefent into any critic or analyfis of this celebrated work. It is univerfally allowed to be replete with much curious and ufeful information; and to abound in narratives which at once excite our admiration and intereft our feelings. The very fingular and extraordinary picture which it gives of Abyffinian manners, ftartled the belief of fome; but thefe manners, though ftrange in the fight of an European, are little more than might be expected in fuch a barbarous country; and had an enlightened philofopher vifited Scotland in the times of our earlieft monarchs, he might perhaps have witneffed and related fcenes, different indeed from what Mr Bruce faw in Abyffinia, but which to us would have feemed equally ftrange.

A more ferious objection to the truth of Mr Bruce's narrative was ftarted by an anonymous, but able, critic,* in an Edinburgh newfpaper, foon after the publication, from the account of two aftronomical phenomena, which *could not poffibly have happened*, as Mr Bruce afferts. The firft of thefe is the appearance of the new moon at Furfhout, during Mr Bruce's ftay in that place, which he mentions to have been from the 25th December 1768 to the 7th of January 1769; and on a particular day in that interval afferts, that the new moon was feen by a fakir, and was found by the ephemerides to be three days old; whereas it is certain that the moon changed on the 8th of January 1769. The other phenomenon appears equally impoffible. At Teawa Mr Bruce fays he terrified the Shekh by foretelling that an eclipfe of the moon was to take place at four afternoon of the 17th of April 1772; that accordingly, foon after that hour, he faw the eclipfe was begun; and when the fhadow was half over, told the Shekh that in a little time the moon would be totally darkened. Now, by calculation, it is certain, that at Teawa this eclipfe muft have begun at 36 minutes paft four, and the moon have been totally covered at 33 minutes paft five; while the fun fet there a few minutes paft fix, before which time the moon, then in oppofition, could not have rifen: fo that as the moon rofe totally eclipfed, Mr Bruce could not fee the fhadow half over the difk, nor point it out to the Shekh. To thefe objections, which appear unfurmountable, Mr Bruce made no reply, though in converfation he faid he would do it in the fecond edition of his book.

* Suppofed to be Dr Rotheram, profeffor of natural philofophy in the univerfity of St Andrew's.

Thefe are miftakes which can hardly be accounted for by attributing them to the inaccuracy of his notes, or indeed to any caufe which we are inclined to name; and perhaps he has fallen into a miftake of the fame kind in his account of the enormous main-fail yard of the *canja*, in which he failed up the river Nile. To every man who has but dipped into the fcience of mechanics, it is known that a beam of wood 200 feet in length, muft be of proportional thicknefs, or it would fall in pieces by its own weight. This thicknefs muft be greatly increafed, to enable it to bear the ftrain occafioned by a prodigious fail filled with wind; and thofe only who have been at the Nile, and have feen the canjas, can fay, whether thefe veffels, or indeed any veffels which can be employed on the river, would not be overfet by yards,

———To equal which, the talleft pine
Hewn on Norwegian hills, to be the maft
Of fome great admiral, were but a wand.

The language of the work is in general harfh and unpolifhed, though fometimes animated. Too great a difplay of vanity runs through the whole, and the apparent facility with which the traveller gained the moft familiar accefs to the courts, and even to the harams of the fovereigns of the countries through which he paffed, is apt to create in readers fome doubts of the accuracy of of the narration. Yet there appears upon the whole ſuch an air of manly veracity, and circumſtances are mentioned with a minuteneſs ſo unlike deceit, that theſe doubts are overcome by the general impreſſion of truth, which the whole detail irreſiſtibly faſtens upon the mind. The character of Ras Michael has often ſtruck us, as containing very ſtrong internal evidence of its having been taken from nature; for it is ſuch a character, at once extraordinary and conſiſtent, as neither Mr Bruce, nor perhaps any writer ſince Shakeſpeare, had genius to feign.

The firſt impreſſion of the book being almoſt diſpoſed of, Mr Bruce had ſtipulated with an eminent bookſeller in London for a ſecond edition to be publiſhed, we think in 8vo; and he was buſy in preparing that edition for the preſs when death removed him from this tranſitory ſtage. On the 26th of April 1794 he entertained ſome company at Kinnaird-houſe with his uſual hoſpitality and elegance. About eight o'clock in the evening, when his gueſts were ready to depart, he was handing one of the ladies down ſtairs, when, having reached the ſeventh or eighth ſtep from the bottom, his foot ſlipped, and he fell down headlong. He was taken up ſpeechleſs; his face, particularly the forehead and temples, being ſeverely cut and bruiſed, and the bones of his hands broken. He continued in a ſtate of apparent inſenſibility for eight or nine hours, and expired on Sunday the 27th, in the 64th year of his age.

Mr Bruce's ſecond wife, whom he married on the 20th May 1776, was Mary, eldeſt daughter of Thomas Dundas, Eſq; of Carron-hall, by Lady Janet Maitland, daughter of Charles ſixth Earl of Lauderdale. By that lady, who, after a ſevere and lingering indiſpoſition, died in 1784, he had three children, of whom one ſon and one daughter ſurvive him.

Mr Bruce's perſon was large, his height exceeding ſix feet, his bulk being in proportion to his height; and at the period when he entered on his dangerous expedition, he was equally remarkable for ſtrength and for agility. To thoſe who never beheld him, the engraved medallion in the title pages of the firſt and third volumes of his Travels will convey ſome idea of his features. He excelled in all manly accompliſhments, being trained to exerciſe and fatigue of every kind. He was a hardy, practiſed, and indefatigable ſwimmer; and his long reſidence among the Arabs had given him a more than ordinary facility in managing the horſe. In the uſe of fire arms he was ſo unerring, that in innumerable inſtances he never failed to hit the mark; and his dexterity in handling the ſpear and lance on horſeback was alſo uncommonly great. He was maſter of moſt languages; and was ſo well ſkilled in oriental literature, that he reviſed the New Teſtament in the Ethiopic, Samaritan, Hebrew, and Syriac, making many uſeful notes and remarks on difficult paſſages. He had applied from early youth to mathematics, drawing, and aſtronomy, and had acquired ſome knowledge of phyſic and ſurgery. His memory was aſtoniſhingly retentive, and his mind vigorous. He was dexterous in negociation, a maſter of public buſineſs, and animated with the warmeſt zeal for the glory of his king and country. Such, at leaſt, is *his own* repreſentation of his character; and though an impartial judge would probably make conſiderable abatement for the natural bias of a man drawing his own portrait, yet it cannot be denied, that in perſonal accompliſhments Mr Bruce equalled, if not exceeded, moſt of his contemporaries.

Thus accompliſhed, he could not but be eminently fitted for an attempt ſo full of difficulty and danger as what he called the diſcovery of the ſources of the Nile: no one who peruſes his account of the expedition, can fail to pay an unfeigned tribute of admiration to his intrepidity, manlineſs, and uncommon dexterity, in extricating himſelf out of ſituations the moſt dangerous and alarming, in the courſe of his long and hazardous journey; not to mention his conduct during his reſidence in Abyſſinia, his behaviour at Maſuah, Teawa, and Sennaar, evinces the uncommon vigour of his mind: but it was chiefly during his paſſage through the Nubian deſert that his fortitude, courage, and prudence, appeared to the greateſt advantage. Of his learning and ſagacity, his delineation of the courſe of Solomon's fleet from Tarſhiſh to Ophir, his account of the cauſe of the inundations of the Nile, and his comprehenſive view of the Abyſſinian hiſtory, afford ample proofs. It muſt indeed be confeſſed, that in his account of the inundations of the Nile, as well as in his delineation of the courſe of Solomon's fleet, he has not the merit of originality; but on both theſe occaſions he has ſtated the hypotheſis which he maintains with greater clearneſs, and ſupported it with more plauſible arguments, than any other author whoſe writings have fallen into our hands; and it was ſurely to his honour, that as ſoon as he learned that his hypotheſis reſpecting Ophir and Tarſhiſh had been controverted by Dr Doig of Stirling, he earneſtly courted the acquaintance of that eminent ſcholar.

After his return to his own country, he reſided moſtly at Kinnaird; and till he became corpulent, ſpent much of his time in the various ſports of the field, in which he engaged with great ardour. Though ſtudious in youth, and at all times a ſtranger to intemperance and diſſipation, he read but little in his later years; and ſeemed to find his chief pleaſure in converſation, eſpecially the converſation of well-informed ladies. In his friendſhips he ſometimes appeared to be capricious, attaching himſelf to men in whoſe heads and hearts no other perſon could perceive a charm for a mind like his. Though in his own dealings he was always juſt and honourable, he was too ready to apprehend unfairneſs in others, and to expreſs ſuch apprehenſions with undue warmth. To ſtrangers he was often arrogant, and ſometimes inſolent; but in his own family he was an affectionate huſband, a kind father, an agreeable entertainer, and to his ſervants a maſter perhaps too indulgent. In converſation, as well as in his writings, he embraced every opportunity of expreſſing a deep and lively ſenſe of the care of a ſuperintending Providence, without which he was convinced that there could be no ſafety in human ſtrength or human foreſight. His belief of the Chriſtian religion reſted on the ſureſt grounds; and ſuch was his veneration for the ſacred writings, that for ſome years before his death they ſeemed to occupy all the time which he gave to ſtudy. He read no ſermons, however elegant; and diſſuaded others from ſuch reading. "Read the Bible (ſaid he), and you will ſoon perceive the emptineſs of the moſt applauded ſermons."

BRUNSWICK, a maritime county in Wilmington diſtrict, N. Carolina, containing 3071 inhabitants, of whom

whom 1511 are slaves. It is the most southerly county of the state, having S. Carolina on the S. W. and bounded by Cape Fear River on the E. Smithville is the seat of Justice.—*Morse.*

Brunswick, the chief town in the above county, situated on the W. side of Cape Fear River; it was formerly the best built in the whole state, and carried on the most extensive trade. It lies 30 miles above the capes, about 9 miles N. of Fort Johnson, 17 S. W. of Wilmington, and was formerly the seat of government. In 1780, it was burnt down by the British, and has now only 3 or 4 houses and an elegant church in ruins.—*ib.*

Brunswick, a township in Essex co. Vermont, on the W. bank of Connecticut River, opposite Stratford, in New-Hampshire.—*ib.*

Brunswick, a city in Middlesex co. New-Jersey, is situated on the S. W. bank of Rariton River, in a low situation; the most of the houses being built under a hill which rises W. of the town. It has between 200 and 300 houses, and about 2500 inhabitants, one half of whom are Dutch. Queen's College was in this city, but is now extinct as a place of instruction. There is a considerable inland-trade carried on here. One of the most elegant and expensive bridges in America, has been built over the river opposite this city. Brunswick is 18 miles N. E. of Princetown, 60 N. E. from Philadelphia, and 35 S. W. from New-York. N. lat. 40 30. W. long. 74. 30.—*ib.*

Brunswick, in Cumberland co. district of Maine, contains 1387 inhabitants, and lies N. E. of Portland 30 miles, and of Boston 151. It is in N. lat. 43. 52. on the S. side of Merry Meeting Bay, and partly on the S. western side of Androscoggin River. Bowdoin College is to be established in this town.—*ib.*

Brunswick, the chief town of Glynn co. Georgia, is situated at the mouth of Turtle River, where it empties into St Simon's sound, N. lat. 31. 10. It has a safe harbor, and sufficiently capacious to contain a large fleet. Although there is a bar at the entrance of the harbor, it has depth of water for the largest ship that swims. The town is regularly laid out, but not yet built. From its advantageous situation, and from the fertility of the back country, it promises to be one of the most commercial and flourishing places in the state. It lies 19 miles S. of Darien; 60 S. S. W. from Savannah, and 110 S. E. from Louisville. —*ib.*

Brunswick *Co.* in Virginia, lies between Nottaway and Meherrin rivers, and is about 38 miles long, and 35 broad, and contains 12,827 inhabitants, including 6776 slaves.—*ib.*

BUCK-wheat, a species of Polyganum (see that article *Encycl.*), was first introduced into Europe about the end of the 15th or the beginning of the 16th century. According to some botanists, who lived at that period, its native country is the northern parts of Asia, whence it was brought to Germany and France, where, about the year 1587, it was the common food of the poor.

A new species of this grain, or, to speak perhaps more properly, a variety of this species, has been for some time known under the name of *Siberian* buck-wheat, which appears to have considerable advantages over the former. It was sent from Tartary to St Petersburgh by the German botanists, who travelled thro' that country in the beginning of the present century; and it has thence been dispersed over all Europe. Linnæus received the first seeds of it in 1737 from Garber the botanist, and described the plant in his *Hortus Cliffortionus*. After this it was mentioned by Ammann in 1739: but it must have been earlier known in Germany; for in 1733 it was growing in the garden of Dr Ehrhart at Memmingen. In Siberia this plant sows itself for four or five years by the grains that drop; but at the end of that period the land becomes so full of tares that it is choaked, and must be sown afresh. Even in the economical gardens of Germany, it is propagated in the same manner; and in that country it is in some places found growing wild, though it is nowhere cultivated in the neighbourhood. In the United States it is cultivated very extensively and is found a valuable article, whether for manure, for sheltering young clover, or for a crop of grain, which is much used for bread and also for feeding cattle.

BUCKS *Co.* in Pennsylvania, lies S. W. from Philadelphia. It is separated from Jersey by Delaware River, on the S. E. and N. E. and has Northampton co. on the N. W. It contains 25,401 inhabitants, including 114 slaves. Bucks is a well cultivated county, containing 411,900 acres of land, and is divided into 27 townships, the chief of which is Newtown. It abounds with lime stone, and in some places are found iron and lead ore. There is a remarkable hill in the N. end of the county called Haycock, in the township of the same name. It is 15 miles in circumference, having a gradual ascent, and from its summit is a delightful prospect. The waters of Tohickon Creek wash it on all sides except the west.—*Morse.*

BULAM, or Bulama, as it is more usually called, forms part of the Archipelago, or cluster of islands, lying on the western or windward coast of Africa, and known by the name of the *Bissaos* or *Bissagos*, which are supposed to have been celebrated by the ancients under the appellation of the *Hesperides*. It is situated at the mouth of the Rio Grande, in 11° N. Lat. and 15° W. Long. from the meridian of London; and is between seventeen and eighteen leagues long, and from four to five broad.

This island has become an interesting object to the inhabitants of Great Britain, in consequence of its having been purchased in the year 1792 by a society instituted for the same humane purposes with those which gave rise to the Sierra-Leone company (see *Sierra-Leone*, Encycl.). The Bulam association was formed towards the latter end of the year 1791; and they were induced to pitch upon that island as the most eligible tract for their intended colony, in consequence of the flattering description given of its climate, soil, and harbours, by M. Brue, formerly director-general of the French African companies.

The gentlemen originally appointed as trustees for managing the concerns of the association at home were, *Paul Le Mesurier*, M. P.; *James Kirkpatrick*, Esq; *George Hartwell*, Esq; *Moses Ximenes*, Esq; *Sir John Riggs Miller*, Bart. and *David Scott*, Esq; M. P; and for establishing the colony, and conducting the affairs of the society abroad, the following gentlemen were nominated, viz. *Messrs H. H. Dalrymple*, *John Young*, *Sir William Halton*, Bart. *John King*, *Philip Beaver*, *Peter Clutterbuck*, Bulama. *Clutterbuck, Nicholas Bayly, Francis Brodie, Charles Drake, John Paiba, Richard Handcorne, Robert Dobbins,* and *Iſaac Ximenes.*

A ſum of L.9000 being quickly ſubſcribed for the eſtabliſhment of the intended colony, this committee failed from Spithead in three ſhips on the 11th of April 1792; and landing in due time at Bulama, they purchaſed that iſland from the kings of Canabac, who claimed it as their property. They purchaſed likewiſe from the kings of Ghinala the neighbouring iſland Arcas, and the adjacent land on the continent; and theſe ſeveral purchaſes being taken poſſeſſion of in the uſual form, a body of ſettlers, conſiſting of 49 men, 13 women, and 25 children, were left at Bulama under the ſuperintendance of Mr Beaver, with a temporary ſupply of proviſions, ſtores, plantation-tools, and merchandiſe, for trading with the neighbouring natives. It is from the diſpatches of theſe ſettlers, after having lived ſome time in Bulama, that the following account of the iſland was drawn up by Mr Johanſen.

" The climate, on the whole, may be deemed ſalubrious, and will become more ſo in proportion to the increaſe of cultivation. The mornings and evenings are temperate and pleaſant; the middle of the day is hot, but the fine ſea-breeze which then ſets in tends greatly to cool and refreſh the air. The heat of the ſun is not either ſo exceſſive or intolerable as has been generally ſuppoſed; indeed nature has moſt admirably adapted our mechanical and phyſical qualities to the exigencies of different regions; and man, who is the inhabitant of every climate, may, in ſome meaſure, render himſelf indigenous to every ſoil. Here the only danger ariſes from too ſudden an expoſure to the operation of the vertical rays of the ſun, or an exceſs of labour; both of which the firſt ſettlers ought moſt ſtudiouſly to avoid.

" It appears from Mr Beaver's obſervations at noon, between the 20th of July 1792, and the 28th of April 1793, that the thermometer, when loweſt, was at 74; the medium heat 85; and that it never exceeded 96, except at one time when it roſe to 100, during a calm that occurred in the interval between the north-eaſt breeze in the morning and the ſouth-weſt in the evening of the 19th of February 1793. The difference between the heat of noon and that of the morning and evening is from 20 to 30 degrees. On the 23d of October 1792, hail of the ſize of a pin's head fell during two minutes, although not a cloud was to be ſeen during this phenomenon. The mercury in the thermometer then ſtood at 85; the wind was at north-eaſt in the morning and ſouth-weſt in the evening.

" Immediately after ſun ſet a dew conſtantly begins to fall, which induces ſome to light a fire in their houſes; they at the ſame time put on warmer clothing. There is little or no twilight; and night and day are nearly equal: the earth has therefore time to cool during twelve hours abſence of the ſun.

" None of thoſe terrible and deſtructive hurricanes ſo frequently experienced in the Weſt Indies are to be met with here. The *tornadoes*, which ariſe chiefly from the eaſtern point of the compaſs, are but of ſhort duration, ſeldom laſting above an hour, and may be readily foreſeen ſome time previouſly to their commencement. They occur at the beginning and cloſe of the wet ſeaſon, and are highly beneficial, as they purify the air, and diſpel the noxious vapours with which it would otherwiſe abound. Bulama.

" The rains ſet in about the latter end of May or the beginning of June, and diſcontinue in October or November. They do not fall every day, for there is often a conſiderable interval of clear weather, during which the atmoſphere is beautifully ſerene; the ſhowers in the firſt and laſt month occur but ſeldom, and are far from being violent; while on the other hand, they ſometimes reſemble torrents, more eſpecially towards the middle of the ſeaſon. During the whole of this period, Europeans ſhould, if poſſible, confine themſelves to their habitations, as the rains prove injurious to health, more eſpecially if thoſe expoſed to them neglect to wipe their bodies dry, and to change their clothes immediately on their return home. It is deemed prudent alſo not to dig the earth until the expiration of a month after the return of fair weather, as this is conſidered to be unhealthy.

" During the continuance of the dry ſeaſon, a dew falls during the night, in ſufficient quantity to anſwer all the purpoſes of vegetation.

" Every ſtranger is generally here, as well as in the Weſt Indies, ſubject to a fever or *ſeaſoning*, on his arrival. This is not infectious; it proceeds perhaps from an increaſed perſpiration and a ſudden extenſion of the pores of the human body, in conſequence of the heat, by which means it is rendered more liable to imbibe the abundant exhalations that ariſe from the animal, vegetable, and mineral kingdoms; but even this, ſlight as it is, might doubtleſs be avoided by means of a proper regimen, and a ſhort ſecluſion from the full action of the open air, more eſpecially at noon, and during the evening, until the climate has been rendered familiar.

" Bulama is admirably adapted for all the purpoſes of an extenſive commerce, being not only happily ſituated at the mouth of the Rio Grande, but in the vicinity of ſeveral other navigable rivers; ſo that a trade with the internal parts of Africa is thereby greatly facilitated. The landing is remarkably eaſy and ſafe, there being no ſurge; the ebb and flow is regular, and there is an increaſe of 16 feet of water at ſpring tide. The bay oppoſite the Great Bulama is adorned with a number of iſlands, covered with trees, and forms a moſt excellent harbour, ſufficiently capacious to contain the whole navy of Great Britain, which might ride there in ſafety. The ſettlement in general is well ſupplied with water. A number of ſprings have been lately diſcovered in different places; and beſides a draw-well in the fort, which was erected for the defence of the colony, there is a ſmall ſtream, which runs into Elewſis Bay, near the new ſettlement called Heſper Elewſis: this is admirably ſituated for the ſupply of ſhipping.

" The iſland is beautifully ſurrounded, and interſperſed with woods: lofty fruit and foreſt trees, moſtly free from underwood and brambles, form a verdant belt, in ſome places two or three miles broad, which entirely encircles it, in ſuch a manner as to repreſent a plantation artificially formed around a park. Within this the fields are regularly divided by trees, ſo as to reſemble the hedge rows in England. The beach has in ſome places the appearance of gravel walks; it is fringed with mangrove trees, which forming a line with the high-water mark, dip their branches into the ſea, and thus afford nouriſhment to the oyſters that often adhere to their extremities.

Several parts of Bulama have been occaſionally cultivated by the neighbouring blacks, though they did not conſtantly reſide on it.

"The land in general riſes gradually towards the middle of the iſland, where the higheſt ſpot is from 60 to 100 feet above the level of the ſea. The ſmall hill on which the fort is ſituated is nearly of the ſame altitude.

"The ſoil is abundantly rich and deep; ſtones do not here impede the labours of the farmer; and indeed none have hitherto been diſcovered, but a ſmall ſort, reſembling pieces of ore, which are to be met with on the ſhore. There are many *ſavannahs* or natural meadows, ſo extenſive that the eye can ſcarcely deſcry their boundaries. Theſe are admirably adapted for the rearing of ſtock and feeding of cattle of every kind.

"Cotton, indigo, rice, and coffee, grow ſpontaneouſly on this coaſt; the ſugar-cane is indigenous to many parts of Africa, and might be cultivated here by the labour of freemen, in equal perfection, and to much greater advantage, than in the exhauſted iſlands of the Weſt Indies. All kinds of tropical productions, ſuch as pine-apples, limes, oranges, grapes, plums, caſſada, guava, Indian wheat, the papaw, water-melon, muſk-melon, the pumkin, tamarind, banana, and numbers of other delicious fruits, alſo flouriſh here. The adjoining territories produce many valuable ſorts of ſpices, gums, and materials for dying; all of which, it is but fair to ſuppoſe, might be readily cultivated in a kindred climate and a congenial ſoil.

"The neighbouring ſeas abound with a variety of fiſh, highly agreeable to the palate. The lion, tyger, jackall, &c. are natives of the continent; but in Bulama no animals have been diſcovered, the wolf, ſome buffaloes, a few elephants, and a ſpecies of the deer excepted.

"The woods abound with doves, guinea fowls, and a variety of birds, celebrated for the beauty of their plumage.

"The natives of this part of Africa, like all ſavages, are entirely under the dominion of their paſſions: hence the violence of their attachment to their friends, and the exceſs of their reſentment againſt their enemies. Their notions of property are very obſcure and confuſed: they have no idea of any right ariſing from occupancy or improvement. What they want, they either receive or take wherever they may happen to meet with it, and they permit others to do the ſame. They have been taught by experience, that the Europeans will not agree to this: againſt them therefore they employ every artifice that it is in the power of cunning to ſuggeſt.

"The coloniſts need not fear any attack on the part of the negroes, provided their own conduct be juſt and peaceable: for Mr Beaver, who was indeed admirably calculated by nature and habit for the ſtation he occupied, could inſure both ſafety and reſpect when the ſettlers under him were reduced to four white men, although the neighbouring nations knew that he was in poſſeſſion of commodities, for the acquiſition of which many of them had become day-labourers. He often kept from twenty to forty gromittos, or black cultivators in pay, at that very period, at about four or five bars (A) each per month. Theſe are eaſy to be procured, to almoſt any number that can poſſibly be wanted.

"Until a ſufficient quantity of ſtock and proviſions can be raiſed in the company's ſettlements, the adjacent iſlands will furniſh abundance of cattle, hogs, fowls, &c. at a very cheap rate. A horſe may be purchaſed at Goree for 1 l. 10 s. a bullock may be had from 12 s. to 18 s. ſterling: proviſions of all kinds are equally reaſonable. Honey is alſo to be procured in great plenty, and bees wax may be rendered an advantageous object of commercial ſpeculation.

"In ſhort, the acquiſition of Bulama, Arcas, and the adjacent territories, preſents the faireſt opportunity of furniſhing Europe with many valuable articles that have hitherto been brought from more remote countries, with much greater hazard, and at an increaſed expence. The intercourſe with England is eaſy, ſafe, and expeditious; for the voyage may be performed in the ſpace of three or four weeks: and by the terms of the firſt ſubſcription, a ſettler on Bulama might purchaſe 500 acres of land for L. 30 ſterling; by the terms of the ſecond, which we ſuppoſe are the terms at preſent, he might purchaſe on the iſlands of Bulama and Arcas, or on that part of the adjacent coaſt which was ceded to the ſociety by the kings of Ghinala, 200 acres for L. 50 ſterling.

"The colonization of Africa opens a noble and extenſive field to nations and to individuals. To people thoſe fertile territories, deſpoiled of their inhabitants by the ſlave-trade; to rear the productions of the climes between the tropics, by the aſſiſtance of free men; to give ample ſcope to the induſtry and exertions of thoſe who may be inclined to remove from Great Britain; and to extend the commerce and the manufactures of our native country—theſe are ſubjects which have excited the attention of the Bulama aſſociation, and now claim the aſſiſtance of the ingenious, the ſupport of the rich, and the concurrence and good wiſhes of all.

BUNCOMB, the largeſt and moſt weſtern county of North Carolina, and perhaps the moſt mountainous and hilly in the United States. It is in Morgan diſtrict, bounded W. by the ſtate of Tenneſſee; and S. by the ſtate of South Carolina. The Blue Ridge paſſes through Buncomb, and gives riſe to many large rivers, as Catabaw, Wateree, Broad River and Pacolet.—*Morse.*

BUNTING, is a bird which has been deſcribed under its generic name Emberiza *(Encycl.)*; but there is one ſpecies, the *orange-ſhouldered bunting* of Latham, of which M. Vaillant relates ſome particulars certainly not unworthy of notice in this place.

"The female of this beautiful bird (ſays he) has the ſimple colours of the ſky lark, and a ſhort horizontal tail, like that of almoſt all other birds: the male, on the contrary, is wholly black except at the ſhoulder of the wing, where there is a large red patch; and his tail is long, ample, and vertical, like that of the common cock. But this brilliant plumage and fine vertical tail ſubſiſt only during the ſeaſon of love, which continues ſix

(A) A bar is about the value of three ſhillings and ſixpence.

fix months. This period over, he lays afide his fplendid habiliments, and affumes the more modeft drefs of his mate. The moft extraordinary circumftance is, that the vertical tail alfo changes to a horizontal one, and the male fo exactly refembles the female, that it is not poffible to diftinguifh them from each other.

"The female has her turn. When fhe reaches a certain age, and has loft the faculty of propagating the fpecies, fhe clothes herfelf for the remainder of her days in the garb which the male had temporarily affumed; her tail, like his at that period, grows long, and, like his alfo, from horizontal becomes vertical.

"The birds of this fpecies affociate together, live in a fort of republic, and build their nefts near to each other. The fociety ufually confifts of about fourfcore females; but whether, by a particular law of nature, more females are produced than males, or for any other reafon of which I am ignorant, there are never more than twelve or fifteen males to this number of females, who have them in common."

According to our author, this tranfmutation is by no means confined to this particular fpecies of bunting. Many females of the feathered creation, when they grow fo old as to ceafe laying eggs, affume the more fplendid colours of the male, which they retain during the remainder of their lives. This fact is ftrikingly perceptible in thofe fpecies in which the male and female very much differ in colour, as the golden pheafant of China, for inftance. In fome fpecies, and thofe not a few, the male alone regularly changes his colour, and affumes once in a year the plumage of the female; fo that at a certain period all the birds of that fpecies appear females. "I have in my poffeffion (fays our author) fpecimens of more than fifty of thofe changing fpecies, in all their tranfitions from one hue to another; and the change is fometimes fo great, that a perfon would fuppofe himfelf to fee individuals totally different. A clofet-naturalift, for inftance, fhewed me four birds as fo many different fpecies, and even as not belonging to the fame genus, with which I was well acquainted, and which I knew to be the fame bird, only of different ages."

Such changes as thefe, could they be proved to take place occafionally among domeftic fowls, would in fome meafure account for ftrange ftories of cocks laying eggs, which we have heard related by perfons whofe general veracity was never queftioned.

BURKE (Edmund), was born in the city of Dublin on the 1ft of January 1730. His father was an attorney of confiderable knowledge in his profeffion, and of extenfive practice; and the family from which he fprung was ancient and honourable. He received the rudiments of his claffical education under Abraham Shackleton, a Quaker, who kept a private fchool or academy, as it has been called, at Bellytore, near Carlow, and is faid to have been a very fkilful and fuccefsful teacher.

Under the tuition of this mafter Burke devoted himfelf with great ardour, induftry, and perfeverance, to his ftudies; and manifefted, even from his boyifh days, a diftinguifhed fuperiority over his contemporaries. He was the pride of his preceptor, who prognofticated every thing great from his genius, and who was, in return, treated by his illuftrious pupil, for forty years, with refpect and gratitude.

From fchool Burke was fent to Trinity-college, Dublin, where it was afferted by Goldfmith and others his contemporaries, that he difplayed no particular eminence in the performance of his exercifes. Like Swift, he defpifed the logic of the fchools; and like him too, he devoted his time and his talents to more ufeful purfuits. Johnfon, though proud of being an Oxonian, did not much employ himfelf in academical exercifes; and Dryden and Milton, who ftudied at Cambridge, were neither of them ambitious of college diftinctions. Let not, however, the example of a Burke, a Johnfon, a Dryden, or a Milton, feduce into by-paths the ordinary ftudent; for though great genius either finds or makes its own way, common minds muft be content to purfue the beaten track. Shakefpeare, with very little learning, was the greateft dramatic poet that ever wrote; but how abfurd would it be to infer from this fact, that every illiterate man may excel in dramatic poetry?

Whilft at college Burke applied himfelf with fufficient diligence to thofe branches of mathematical and phyfical fcience which are moft fubfervient to the purpofes of life; and though he neglected the fyllogiftic logic of Ariftotle, he cultivated the method of induction pointed out by Bacon. Pneumatology, likewife, and ethics, occupied a confiderable portion of his attention; and whilft attending to the acquifition of knowledge, he did not neglect the means of communicating it. He ftudied rhetoric and the art of compofition, as well as logic, phyfics, hiftory, and moral philofophy; and had at an early period of his life, fays Dr Biffet, planned a confutation of the metaphyfical theories of Berkeley and Hume.

For fuch a tafk as this, we do not think that nature intended him. Through the ever-active mind of Burke ideas feem to have flowed with too great rapidity to permit him to give that patient attention to minute diftinctions, without which it is vain to attempt a confutation of the fubtleties of Berkeley and Hume. The ableft antagonift of thefe two philofophers was remarkable for patient thinking, and even *apparent* flownefs of apprehenfion; and we have not a doubt, but that if he had poffeffed the rapidity of thought which charactefifed Burke, his confutation of Hume and Berkeley would have been far from conclufive: It might have been equal to the *Effay on the Nature and Immutability of Truth*, but would not have been what we find it in *The Inquiry into the Human Mind on the Principles of Common Senfe*, and in *The Effays on the Intellectual and Active Powers of Man*.

A tafk much better fuited to Burke's talents than the writing of metaphyfical difquifitions on the fubftratum of body, prefented itfelf to him in the year 1749, and a tafk which was likewife more immediately ufeful. At that period one Lucas, a democratic apothecary, wrote a number of very daring papers againft government, and acquired by them as great popularity at Dublin as Mr Wilkes afterwards obtained by his North Briton in London. Burke, though a boy, perceived, almoft intuitively, the pernicious tendency of fuch levelling doctrines, and refolved to counteract it. He wrote feveral effays in the ftyle of Lucas, imitating it fo exactly as to deceive the public; purfuing his principles to confequences neceffarily refulting from them, and fhewing at the fame time their abfurdity and their danger.

Burke. danger. Thus was his firſt literary effort, like his laſt, calculated to guard his country againſt anarchical innovations.

Whilſt employed in treaſuring up knowledge, which at a future period was to command the admiration of liſtening ſenates, he did not neglect the means neceſſary to render himſelf agreeable in the varied intercourſe of private life. To the learning of a ſcholar he added the manners of a gentleman. His company was ſought among the gay and the faſhionable, for his pleaſing converſation and eaſy deportment; as much as among the learned, for the force and brilliancy of his genius, and the extent and depth of his knowledge. But though the object of very general regard in his native country, he had hardly any proſpect of obtaining in it an independent ſettlement. He therefore applied, ſome time after the publication of his letters expoſing the doctrines of Lucas, for the profeſſorſhip of logic, which had then become vacant in the univerſity of Glaſgow: but whether that application was made too late, or that the univerſity was unwilling to receive a ſtranger, certain it is that the vacant chair was filled by another, and that Burke was diſappointed of an office in which he was eminently qualified to excel. For many years very little attention has been paid in the univerſities of Scotland, perhaps even too little, to the Ariſtotelian logic; and the profeſſors, inſtead of employing their time in the analyſing of ſyllogiſms, deliver lectures on rhetoric and the principles of compoſition—lectures which no man was more capable of giving than the unſucceſsful candidate for the profeſſorſhip in Glaſgow.

Diſappointment of early views has frequently been the means of future advancement. Had Johnſon become maſter of the Staffordſhire ſchool, talents might have been conſumed in the tuition of boys which Providence formed for the inſtruction of men; and had Burke obtained the profeſſorſhip of logic in Glaſgow, he would have been the moſt eloquent lecturer in that univerſity, inſtead of the moſt brilliant ſpeaker in the Britiſh ſenate: but whether his talents might not have been as uſefully employed in the univerſity as in the ſenate, may perhaps be a queſtion, though there can be no queſtion whether they would have inveſted himſelf with an equal blaze of ſplendour.

Diſappointed in Glaſgow, he went to London, where he immediately entered himſelf of the Temple; and as there is reaſon to believe that he was in ſtraitened circumſtances, he ſubmitted to the drudgery of regularly writing for daily, weekly, and monthly publications, eſſays on general literature and particular politics. The profits ariſing from ſuch writings were at firſt ſmall; but they were ſo neceſſary to their author, that the intenſe application which they required gradually impaired his health, till at laſt a dangerous illneſs enſued, when he reſorted for medical advice to Dr Nugent, a phyſician whoſe ſkill in his profeſſion was equalled only by the benevolence of his heart. The Doctor, conſidering that the noiſe, and various diſturbances incidental to chambers, muſt retard the recovery of his patient, furniſhed him with apartments in his own houſe, where the attention of every member of the family contributed more than medicines to the reſtoration of his health. It was during this period that the amiable manners of Miſs Nugent, the Doctor's daughter, made a deep impreſſion on the heart of Burke; and as ſhe could not be inſenſible to ſuch merit as his, they felt for each other a mutual attachment, and were married ſoon after his recovery. Burke.

Hitherto his mental powers and acquirements were known in their full extent only to his friends and more intimate companions; but they were now made public in his firſt acknowledged work, intitled, *A Vindication of Natural Society*. The object of this performance was to expoſe the dangerous tendency of Lord Bolingbroke's philoſophy. By the admirers of that nobleman his principles were deemed inimical only to revealed religion and national churches, which they would have been glad to ſee overturned, provided our civil eſtabliſhment had been preſerved; and to the civil eſtabliſhment they perceived no danger in the writings of the author of *The Patriot King*. Mr Burke thought very differently; and endeavoured to convince them, that if his Lordſhip's philoſophy ſhould become general, it would ultimately deſtroy their rank, their conſequence, and their property, and involve the church and ſtate in one common ruin. In his ironical attack upon artificial ſociety, he makes uſe of the ſame common-place mode of unfair reaſoning which his noble antagoniſt had employed againſt religion and religious eſtabliſhments. He argues, from the incidental abuſes of political ſociety, that political ſociety muſt itſelf be evil; he goes over every form of civil polity, pointing out its defects in the moſt forcible language; and, in perfect imitation of the ſceptical philoſophy, he pulls them all down, one after another, without propoſing any thing in their ſtead. So complete is the irony, that to many not acquainted with ſuch diſquiſitions, he would appear to be ſeriouſly inveighing againſt civil government: and we have actually heard ſome of the advocates for modern innovation mention this work as a proof how different Mr Burke's opinions in politics once were from what they appear to have been when he wrote his *Reflections on the French Revolution*.

The truth, however, is, that there is no inconſiſtency between *The Vindication of Natural Society* and the lateſt publications of its illuſtrious author. At the period when that work was publiſhed, infidelity had infected only the higher orders of men, and ſuch of the lower as had got the rudiments of a liberal education. Of theſe we believe a ſingle individual was not then to be found, who ſuppoſed that ſociety could ſubſiſt both without government and without religion; and therefore whilſt they laboured to overturn the church, and to prove that Chriſtianity itſelf is an impoſture, they all pretended to be zealouſly attached to the civil government as eſtabliſhed in king, lords, and commons. Except the clergy of the eſtabliſhed church, there was no order of men whom they indiſcriminately reviled. Hence it was that not Burke only, but Warburton, and almoſt every other opponent of Lord Bolingbroke, began their defences of revelation, by ſhewing the indiſſoluble connection between the civil and eccleſiaſtical eſtabliſhments, and all the difference was, that he did, through the medium of the moſt refined irony, the very ſame thing which they had done by ſerious reaſoning.

Soon after his *Vindication of Natural Society*, Burke publiſhed *A Philoſophical Enquiry into the Origin of our Ideas of the Sublime and Beautiful*; a work which ſoon made its author univerſally known and admired, and which has been ſtudied by every Engliſh reader of taſte.

It

Burke.

It is therefore needlefs for us to hazard any opinion either of its general merit or its particular defects. In one of the literary journals of that day, Mr Murphy urged objections againft fome of its fundamental principles, which, in our opinion, it would be very difficult to anfwer; whilft Johnfon, who was certainly a fevere judge, confidered it as a model of philofophical criticifm. "We have (faid he) an example of true criticifm in Burke's Effay on the Sublime and Beautiful. There is no great merit in fhewing how many plays have ghofts in them, or how this ghoft is better than that; you muft fhew how terror is impreffed on the mind."

In confequence of this manifeftation of Burke's intellectual powers, his acquaintance was courted by men of diftinguifhed talents, and, among others, by Johnfon and Sir Jofhua Reynolds. The literary club, which has been mentioned *(Encycl.)* in the life of Johnson, was inftituted for their entertainment and inftruction, and confifted at firft of Johnfon, Burke, Reynolds, Goldfmith, Dr Nugent, Mr Topham, Beauclerc, Sir John Hawkins, Mr Chamier, and Mr Bennet Langton, who were all men of letters and general information, though far above the reft ftood Burke and Johnfon. Of Burke indeed, Johnfon declared, upon all occafions, that he was the greateft man living; whilft Burke, on a very folemn occafion, faid of Johnfon, "He has made a chafm, which not only nothing can fill up, but which nothing has a tendency to fill up. Johnfon is dead. Let us go to the next beft—There is nobody—No man can be faid to put you in mind of Johnfon." Nor was the opinion which thefe two illuftrious men held of each other's powers peculiar to themfelves alone: all the members of the club obferved, that, in colloquial talents, they were nearly matched, and that Johnfon never difcourfed with fuch animation and energy as when his powers were called forth by thofe of Burke.

Some years before the inftitution of this club, Burke, who had devoted much of his time to the ftudy of hiftory and politics, propofed to Mr Dodfley, an eminent bookfeller, a plan of an Annual Register of the civil, political, and literary tranfactions of the times; and the propofal being acceded to, the work was begun and carried on for many years, either by Burke himfelf, or under his immediate infpection. It bears indeed internal marks of his genius, his learning, and his candour, being by much the moft elegant and impartial periodical hiftory which has perhaps appeared in any age or nation. Even when the heat of oppofition made him, in his fpeeches, fometimes mifreprefent the conduct of adminiftration, the Annual Regifter, under his management, continued to render juftice to all parties.

He ftill continued to write occafionally political effays for other publications than the Annual Regifter; and fome of thefe effays in the *Public Advertifer* having attracted the notice of the Marquis of Rockingham, that nobleman fought the acquaintance of their author. It was in the year 1765 that the firft interview took place between them; and the Marquis, who was then at the head of the treafury, offering to make Burke his own fecretary, the offer was readily accepted. On this occafion he gave a remarkable proof of difintereftednefs and delicate integrity. Through the influence of Mr Hamilton, known by the appellation of *Single-Speech* Hamilton, and long fufpected to be the author of *Junius's Letters*, he had fome time before obtained a penfion of L. 300 a year on the Irifh eftablifhment; but this penfion he now thought it incumbent upon him to refign, becaufe he had connected himfelf with a party oppofite in many things to the party whofe meafures were fupported by his friend.

During the Rockingham adminiftration he was chofen member of parliament for the borough of Wendover in the county of Bucks; and he prepared himfelf for becoming a public fpeaker, by ftudying, ftill more clofely than he had yet done, hiftory, poetry, and philofophy; and by ftoring his mind with facts, images, reafonings, and fentiments. He paid great attention likewife to parliamentary ufage; and was at much pains to become acquainted with old records, patents, and precedents, fo as to render himfelf complete mafter of the bufinefs of office. That he might communicate without embarraffment the knowledge which he had thus laborioufly acquired, he frequented, with many other men of eminence, the Robin Hood Society, where he practifed the replies and contentions of eloquence; and to acquire a graceful action, with the proper management of his voice, he was a very diligent obferver of Garric in Drury-Lane theatre. He procured his feat in 1765, and in the enfuing feffion delivered his maiden fpeech; which was fuch a difplay of eloquence as excited the admiration of the Houfe, and drew very high praife from its moft diftinguifhed member Mr Pitt, afterwards Earl of Chatham.

The principal objects which engaged the attention of the Rockingham adminiftration were the ferments in America, which was then in a ftate little fhort of rebellion, on account of the famous ftamp-act. Parliament was divided in opinion refpecting that meafure. Whilft Mr Grenville and his party (under whofe aufpices the ftamp-act had paffed into a law) were for enforcing obedience to it by coercive meafures, Mr Pitt and his followers denied that the parliament of Great Britain had a right to tax the Americans; and the marquis of Rockingham, who was hardly able to carry any meafure in oppofition to both thefe parties, had to confider, on this occafion, whofe fentiments he would adopt. By the advice, it is faid of Mr Burke, he chofe a middle courfe between the two oppofite extremes. To gratify the Americans, he repealed the ftamp-act; and to vindicate the honour of Britain, he got a law paffed declaratory of her right to legiflate for America in taxation as in every other cafe.

This meafure, whoever was its author, was certainly not the offspring either of wifdom or vigour. If the mother country had a right to legiflate in all cafes for America, obedience to the ftamp-act fhould certainly have been enforced; and the miniftry which relinquifhed an acknowledged right, to gratify the difpofition of diftant colonies, was confidered as unfit to guide the helm of a great empire. Lord Rockingham and his friends were accordingly difmiffed from office; and a new adminiftration was formed under the aufpices of Mr Pitt, now created Earl of Chatham.

Burke, in the mean time, wrote in defence of the party with which he was connected; and affumed great credit to it for compofing the diftractions of the Britifh empire by the repeal of the American ftamp-act, whilft the conftitutional fuperiority of Great Britain was preferved by the act for fecuring the dependence of

Burke. of the colonies. After defending his friends, he proceeds to attack thofe who had fucceeded them in office. Of Lord Chatham he fays—"He has once more deigned to take the reins of government into his own hand, and will, no doubt, drive with his wonted fpeed, and raife a deal of duft around him. His horfes are all matched to his mind; but as fome of them are young and fkittifh, it is faid he has adopted the new contrivance lately exhibited by Sir Francis Delaval on Weftminfter bridge: whenever they begin to fnort and tofs up their heads, he touches the fpring, throws them loofe, and away they go, leaving his lordfhip fafe and fnug, and as much at his eafe as if he fat on a woolpack."

The letter, of which this is an extract, was printed in the Public Advertifer; and is faid to have contributed, in no fmall degree, to leffen the popularity of the illuftrious ftatefman againft whom it was written. The miniftry, indeed, which he had formed, confifted of very heterogeneous materials, and was not heartily approved of by the nation. It therefore foon fell in pieces by its own difcord, and Lord Chatham retired in difguft.

The parliament being diffolved in 1768, Burke was re-elected for Wendover, and took his feat, when the houfe met, in November. The duke of Grafton was now prime minifter, and was oppofed by two powerful parties in parliament; that of the marquis of Rockingham, and that of which Mr Grenville was confidered as the leader. Thefe two parties, however, differed widely between themfelves. Mr Grenville had publifhed a pamphlet, intitled, *The Prefent State of the Nation;* in which he very ably vindicated his own meafures, and of courfe condemned the meafures of thofe who had fucceeded him; and Burke replied to him, with greater eloquence, but, perhaps, with lefs of argument, in a tract, intitled *Obfervations on the Prefent State of the Nation*, in which he makes a very high panegyric on his own patron, and the connections of the party, and animadverts with cutting feverity on their fucceffors in office.

About this period commenced the national frenzy which was excited by the expulfion of Wilkes from the houfe of commons, *for having printed and publifhed a feditious libel, and three obfcene and impious libels.* In the controverfy to which this tranfaction gave rife, Burke and Johnfon took oppofite fides. Johnfon, in his *Falfe Alarm*, contends, with great ability, that the expulfion of a member from the houfe of commons for the commiffion of a crime, amounts to a difqualification of that member from fitting in the parliament from which he is expelled; whilft Burke, though he difapproved of the conduct of Wilkes as much as his friend, laboured to prove, that nothing but an act of the legiflature can difqualify any perfon from fitting in parliament who is regularly chofen, by a majority of electors, to fill a vacant feat. It does not appear that this difference of opinion produced the fmalleft abatement of mutual regard between him and Johnfon. They both attended the weekly club, and were as much pleafed with each other as formerly.

The proceedings of the Grafton adminiftration, refpecting Wilkes and other fubjects, gave rife to the celebrated *Letters of Junius*. That thofe compofitions were, in clearnefs, neatnefs, and precifion of ftyle, infinitely fuperior to perhaps every other feries of newfpaper invectives, has never been controverted; and that they difplay a vaft extent of hiftorical and political information, is known to all who are not themfelves ftrangers to the hiftory of Great Britain. Unclaimed by any author, and fuperior to the productions of moft authors, they have been given to Burke, to his brother Richard, a man likewife of very bright talents, to Mr Hamilton, and to Lord George Germaine. We fhould hardly hefitate to adopt the opinion of thofe who afcribe them to Burke, had he not difavowed them to his friend Johnfon. "I fhould have believed Burke to be Junius (faid Johnfon), becaufe I know no man but Burke who is capable of writing thefe letters; but Burke *fpontaneoufly* denied it to me. The cafe would have been different had I *afked* him if he was the author. A man may think he has a right to deny when fo queftioned as to an anonymous publication." The difference between the ftyle of thefe letters and that of Burke's acknowledged writings, would have had no weight with us; becaufe fuch was his command of language, that he could affume, and occafionally did affume, any ftyle which he chofe to imitate. He had already fo clofely imitated the very different ftyles of Lucas and Bolingbroke as to deceive the public; and what was to hinder him from imitating the ftyle of Lord George Germaine, which certainly has a ftrong refemblance to that of Junius? We think, however, with Johnfon, that his *fpontaneous difavowal* of thefe letters ought to be held as fufficient proof that he was not their author.

Burke had now gotten a very pleafant villa near Beaconsfield in Buckinghamfhire; and being one of the freeholders of the county, he drew up a petition to the king, complaining of the conduct of the houfe of commons refpecting the Middlefex election, and praying for a diffolution of the parliament. The petition, though explicit and firm, was temperate and decorous, and as unlike to one on the fame fubject from the livery of London, as the principles of a moderate Whig are to thofe of a turbulent democrate.

About this period he ftated very clearly his own political principles in a pamphlet intitled, "Thoughts on the Caufes of the Prefent Difcontents;" and his plan for removing thefe difcontents had not a grain of democracy in its compofition. He propofed to place the government in the hands of an open ariftocracy of talents, virtue, property, and rank, combined together on avowed principles, and fupported by the approbation and confidence of the people; and the ariftocracy which he thought fitteft for this great truft, was a combination of thofe Whig families which had moft powerfully fupported the revolution and confequent eftablifhments. He expreffed, in ftrong terms, his difapprobation of any change in the conftitution and duration of parliament; and declared himfelf as averfe from an adminiftration which fhould have no other fupport than popular favour, as from one brought forward merely by the influence of the court.

In this plan there is not that wifdom or liberality which might have been expected from a man of Burke's cultivated mind and extenfive reading. The Whigs, when in power, had been as venal as the Tories; and the imprifonment of Lord Oxford, the banifhment of Atterbury bifhop of Rochefter, and the refolution of the

the houſe of commons to ſit for ſeven years, when it had been choſen by its conſtituents for no more than three, were certainly greater violations of the conſtitution than the diſqualification of Wilkes, or any other meaſure that had been carried by the court during the adminiſtrations of Grenville and the duke of Grafton. Burke ſhewed himſelf in this publication to be indeed no republican; but every ſentence of it breathed the ſpirit of party.

Lord North was now prime miniſter; and in order to tranquillize America, he propoſed, in the beginning of his adminiſtration, to repeal the obnoxious laws of his predeceſſors in office, and to reſerve the duty on tea merely to maintain the authority of parliament. The conſequences of this conduct we have detailed elſewhere (ſee Britain, *Encycl.*); and they are too well known to all our readers. The part which Burke acted during his adminiſtration will not, in our opinion, admit of any plauſible defence. It was not indeed the part of a democrate, but of a man determined to oppoſe every meaſure of thoſe in power. In the beginning of the conteſt, he certainly diſplayed more wiſdom and patriotiſm than the miniſter; for, without entering directly into the queſtion Whether the mother-country had or had not a right to tax the colonies? he contented himſelf with warning the houſe againſt dangerous innovations. "The Americans (ſaid he) have been very ſerviceable to Britain under the old ſyſtem: do not, therefore, let us enter raſhly upon new meaſures. Our commercial intereſts have been hitherto greatly promoted by our friendly intercourſe with the colonies; do not let us endanger poſſeſſion for contingency; do not let us ſubſtitute untried theories for a ſyſtem experimentally aſcertained to be uſeful."

This was undoubtedly ſound reaſoning, and everyway becoming a lover of his country: but his continued oppoſition to government, after all Europe had leagued againſt Great Britain, was a conduct which will admit of no vindication, and for which the only poſſible apology muſt be found in that ardour of temper which made his friend Hamilton ſay, on another occaſion, "Whatever opinion Burke, from any motive, ſupports, ſo ductile is his imagination, that he ſoon conceives it to be right." In his moſt violent oppoſition, however, though his expreſſions were often extravagant and indecent, he never for a moment gave his ſupport to the metaphyſical doctrine of the *impreſcriptible rights of man*, or to the actual innovations which ſome meant to introduce on the baſis of that doctrine. His upright mind was indeed ſufficiently guarded againſt theſe novelties by what he had obſerved in France during the year 1772. Whilſt he remained in that country, his literary and political eminence made him courted by all the anti-monarchical and infidel philoſophers of the time; and in the religious ſcepticiſm and political theories of Voltaire, Helvetius, Rouſſeau, and D'Alembert, he ſaw, even at that period, the probable overthrow of religion and government. His ſentiments on this ſubject he took occaſion, immediately on his return, to communicate to the houſe of commons; and to point out the conſpiracy of atheiſm to the watchful policy of every government. He profeſſed, that he was not over fond of calling in the aid of the ſecular arm to ſuppreſs doctrines and opinions; but he recommended a grand alliance among all believers againſt thoſe miniſters of rebellious darkneſs, who were endeavouring to ſhake all the works of God eſtabliſhed in beauty and in order.

The American war proving unſucceſsful, though Great Britain never made a more glorious ſtand, Lord North and his friends retired from office; and, in February 1782, a new miniſtry was formed, at the head of which was placed the marquis of Rockingham; Lord Shelburne and Mr Fox were the ſecretaries of ſtate; and Mr Burke, who was appointed pay-maſter to the forces, exulted, rather childiſhly, in the houſe of commons, on the happineſs which was to accrue, both to the king and to the people, from the able and upright conduct of the new miniſters. The time in which the greater part of them continued in office was too ſhort to permit them to do either much good or much evil.

On the 1ſt of July the marquis of Rockingham died; and the earl of Shelburne being placed at the head of the treaſury, Fox and Burke reſigned in diſguſt, and, to the aſtoniſhment of the nation, formed the famous coalition with Lord North, whoſe meaſures they had ſo long, and ſo vehemently oppoſed. In the coalition of North and Burke there would have been nothing wonderful. In the intercourſe of private life, theſe two ſtateſmen had always met on terms of friendſhip and mutual regard; they had the ſame ideas of the excellence of the conſtitution, and the ſame averſion to innovation under the name of reform; even their ſtudies and amuſements were very ſimilar, being both men of taſte and claſſical learning; and though Burke oppoſed the taxation of America by the Britiſh parliament, his oppoſition proceeded rather from motives of prudence and expediency than from any ſettled conviction that the meaſure was unconſtitutional. But the political enmity of Fox and North had proceeded, not only to perſonal abuſe, but to profeſſions of mutual abhorrence; and perhaps there was hardly an unprejudiced perſon in the kingdom who entertained not ſuſpicions, that the unexpected union of ſuch enemies was cemented by a principle leſs pure than patriotiſm.

Mr Pitt was now chancellor of the exchequer; and when he announced to the houſe of commons the peace which was concluded in January 1783, he found the terms on which it had been made ſeverely condemned by North, Fox, Burke, and all their friends. The cenſure paſſed on it by Lord North and his followers was perfectly conſiſtent with their former conduct, and with the opinions which they had uniformly maintained; but it was with no good grace that Fox and Burke, who had offered an unconditional peace to the Dutch, and ſo frequently propoſed to recognize the independence of America, condemned the peace which had been concluded by Lord Shelburne. On this, as on many other occaſions, they acted, not as enlightened politicians, but as the rancorous leaders of a party.

In conſequence of a vote of cenſure paſſed by the commons, the miniſters reſigned their employments, and were ſucceeded by the duke of Portland, Lord North, Mr Fox, Mr Burke, and their friends. Burke had his former employment of pay-maſter to the forces; Lord North and Mr Fox were ſecretaries of ſtate, and the duke of Portland was firſt lord of the treaſury. To many perſons this miniſtry had the appearance of greater ſtrength than any that had governed the kingdom ſince the time of Sir Robert Walpole; but its duration was not longer than that of the preceding. On the

the 18th of November, Mr Fox introduced his famous India-bill, into the merits of which it is foreign from our purpofe to enter: fuffice it to fay, that after being ftrongly fupported by Burke, and ably oppofed by Pitt and Dundas, it paffed the houfe of commons by a very great majority; but was loft in the houfe of peers, and viewed by the king in fuch a light, that he determined on an entire change of adminiftration.

Mr Pitt was now placed at the head of the treafury, where he has remained ever fince, notwithftanding the violent and powerful oppofition which he met with at firft from North and Fox and their coalefced friends: the voice of the nation has been on his fide; and that voice will always drown the bellowings of patriotifm.

The principal events in which Burke fignalized himfelf, fince the year 1784, were the trial of Haftings, the deliberations of the houfe on the propofed regency during the lamented illnefs of the king, and the French revolution; and on each of thefe occafions he difplayed talents which aftonifhed the nation. He has, indeed, been feverely blamed for the pertinacity with which he profecuted Mr Haftings, and his conduct has been attributed to very unworthy motives; but of this there is neither proof nor probability. The temperament of his mind was fuch, that, into whatever meafure he entered, he entered with a degree of ardour of which cooler heads can hardly form a conception. Burke was but one member of a committee which found, or thought it found, evidences of the guilt of Haftings; and, in forming his opinion, it is little likely that he fhould have been biaffed by intereft or refentment, whofe delicate fenfe of rectitude would not permit him to retain a penfion when he could no longer fupport the party of that friend who had obtained it for him.

When the eftablifhment of a regency was thought neceffary, he took the part, as it was called, of the prince of Wales, in oppofition to the plan propofed by Lord Thurlow and the minifter; and we doubt not but he was actuated by the pureft principles: but the language which he ufed in the houfe was vehement, and fome of his expreffions were highly indecent. Our regard for his memory makes us wifh to forget them.

Soon after the recovery of the king, the attention of Burke was attracted to the moft momentous event of modern times;—an event which has convulfed all Europe, and of which, from the very firft, his fagacity forefaw the confequences. Many of his friends in parliament, as well as numbers of wife and good men out of it, augured, from the meeting of the ftates general of France, great benefit to that nation, of which the government was confidered as defpotic and oppreffive; and fome were fanguine enough to prognofticate a new and happy order of things to all the nations connected with France, when its government fhould become more free. Burke thought very differently: He was well acquainted with the genius of the French people, and with the principles of thofe philofophers, as they called themfelves, by whom a total revolution in church and ftate had long been projected; and from the commencement of their career in the conftituent affembly, when they eftablifhed, as the foundation of all legal government, the metaphyfical doctrine of *the rights of man*, he predicted that torrent of anarchy and irreligion which they have fince attempted to pour over all Europe. Fox and fome of the other leading men in oppofition affected to confider this as a vain fear; and a coolnefs took place between them and Burke, though they ftill acted together in parliament. At laft, perceiving the French doctrines of liberty and equality and atheifm, fpreading through this nation, not only among thofe who had talents for fuch difquifitions, but in clubs and focieties, of which the members could be no judges of metaphyfical reafonings, he expreffed his apprehenfion of the confequences in the houfe of commons. This brought on a violent altercation between him and Fox, who was fupported by Sheridan; and a rupture took place between thefe old friends which was never healed. He no more attended the meetings of the oppofition members; and in 1790 he publifhed his celebrated *Reflections on the French Revolution*.

By the friends of government this work was admired as the moft feafonable, as well as one of the ableft, defences of the Britifh conftitution that ever was written; whilft Fox and his friends, with the great body of Englifh diffenters, though they admitted it to be the offfpring of uncommon genius, affected to confider it as declamatory rather than argumentative, and as inconfiftent with the principles which its author had hitherto uniformly maintained. Many anfwers were written to it; of which the moft confpicuous were *Vindiciæ Gallicæ* by Mr Mac Intofh, and *The Rights of Man* by Thomas Paine. To thefe Burke deigned not to make a direct reply. He vindicated his general principles, as well as fome of his particular reafonings, in *A Letter to a Member of the National Affembly*; and he very completely evinced the confiftency of his principles in his *Appeal from the New to the Old Whigs*.

Of this great work, for great it undoubtedly is, the merits as well as the demerits have been much exaggerated; and fome have made it a queftion, Whether it has on the whole been productive of good or of harm? By the enemies of the author, it is reprefented as having given rife to the fpirit of difcontent, by exciting fuch writers as Paine and his adherents, who, but for the provocation given by *The Reflections*, might have remained in filence and obfcurity. This was from the firft a very improbable fuppofition; for the fpirit of democracy has at all times been reftlefs: but fince the appearance of Profeffor Robifon's *Proofs of a confpiracy*, and Barruel's *Hiftory of Jacobinifm*, it muft be known to every reader to be a fuppofition contrary to fact. The confpirators were bufy long before Burke wrote his *Reflections*; and the friends of order and religion are his debtors, for having fo forcibly roufed them from their flumber, and put them on their guard. With refpect to compofition, it is certainly neither fo energetic nor fo argumentative as the political tracts of Johnfon, to which fome have affected to confider it as fuperior; but it is more poetical, gives fcope for a greater difplay of the knowledge of human nature; and being written on a more interefting fubject, it has had a much greater number of readers than thofe unrivalled pieces of political controverfy.

Burke being now affociated with Mr Pitt, continued to write from time to time memorials and remarks on the ftate of France, and the alliance that was formed againft the new order of things in that diftracted country, of which fome have been publifhed fince his death; and having refolved to quit the buftle of public life as foon as the trial of Mr Haftings fhould be concluded, he

Burke. he vacated his feat when that gentleman was acquitted, and retired to his villa at Beaconsfield, where on the 2d of Auguft 1794 he met with a heavy domeftic lofs in the death of his only fon. In the beginning of the fame year he had loft his brother Richard, whom he tenderly loved: but though this reiterated ftroke of death deeply affected him, it never relaxed the vigour of his mind, nor leffened the intereft which he took in the public weal.

In this retreat, while he was labouring for the good of all around him, he was difturbed by a very unprovoked attack upon his character by fome diftinguifhed fpeakers in the houfe of peers. Soon after the death of his fon the king was gracioufly pleafed to beftow a penfion on him and Mrs Burke; and this thofe noble lords were pleafed to reprefent as the reward of what they termed the change of his principles and the defertion of his friends. The injuftice of this charge muft be obvious to every impartial mind, fince the penfion was given after he had retired from parliament, and could not by his eloquence either fupport the miniftry or gall the oppofition. He was not a man to fubmit tamely to fuch an infult. He publifhed a letter on the occafion, addreffed to a noble lord (Earl Fitzwilliam), in which he repels the attack on his character, and retaliates on thofe by whom it was made, in terms of fuch eloquent and keen farcafm, as will be read with admiration as long as the language of the letter fhall be underftood.

Burke having employed every effort which benevolence and wifdom could devife to ftimulate civilized governments to unite in oppofition to the impiety and anarchy of France, laboured likewife in private to relieve thofe who had fuffered exile and profcription from the direful fyftem. Through his influence a fchool was eftablifhed in his neighbourhood for the education of thofe whofe parents, for their adherence to principle, were rendered unable to afford to their children ufeful inftruction; and that fchool, which on his deathbed he recommended to Mr Pitt, continues to flourifh under his powerful protection.

When the appearance of melioration in the principles and government of France induced our fovereign to make overtures of peace to the French directory, Burke refumed his pen; and in a feries of letters, intitled, *Thoughts on the Profpect of a Regicide Peace*, difplayed a force of genius which is certainly not furpaffed, and perhaps not equalled, even in his far famed *Reflections on the French Revolution*. This was his laft work, and was confidered by himfelf as in its nature teftamentary.

From the beginning of June 1797 his health rapidly declined; but his underftanding exerted itfelf with undiminifhed force and uncontracted range; and his difpofitions retained all their amiable fweetnefs. On the 7th of July, when the French revolution was mentioned, he fpoke with pleafure of the confcious rectitude of his own intentions in what he had done and written refpecting it; intreated thofe about him to believe, that if any unguarded expreffion of his on the fubject had offended any of his former friends, no offence was by him intended; and he declared his unfeigned forgivenefs of all who had on account of his writings, or for any other caufe, endeavoured to do him an injury. On the day following he defired to be carried to another room; and whilft one of his friends, affifted by fome fervants, was complying with his requeft, Mr Burke faintly uttering, "God blefs you," fell back and expired in the 68th year of his age.

Burke || Burlington.

From this detail, we truft that our readers are already fufficiently acquainted with his general character. In genius, variety of knowledge, and readinefs of expreffion, Johnfon alone of all his contemporaries could be confidered as his rival; and, like that great man, he took every opportunity, efpecially during his laft illnefs, to declare his unfhaken belief of the Chriftian religion, his veneration for fincere Chriftians of all perfuafions, and his own preference of the church of England. On the worfhip of that church he had indeed through the whole of his life been a regular and devout attendant; and the tears which the poor, in the neighbourhood of his villa, fhed at his funeral, gave fufficient evidence that his faith had been productive of charity. In his public conduct, the irritability of his temper, and the ardour of his imagination, fometimes hurried him into the exceffes of a mere party-man; but we believe that his great religious and political principles never varied. He has himfelf characterifed his public conduct in the conclufion of his Reflections on the French Revolution, when he fays, that "they come from one who has been no tool of power, no flatterer of greatnefs, and who in his laft acts does not wifh to belie the tenor of his life; from one who wifhes to preserve confiftency, but who would preserve confiftency by varying his means to fecure the unity of his end; and when the equipoife of the veffel in which he fails may be endangered by overloading it upon one fide, is defirous of carrying the fmall weight of his reafons to that which may preferve the equipoife."

BURKE *Co.* in Morgan diftrict, N. Carolina, has 8118 inhabitants, including 595 flaves. Its capital is Morgantown.—*Morse.*

BURKE *Co.* in the Lower diftrict of Georgia, contains 9467 inhabitants, including 595 flaves. Its chief towns are Louifville, and Waynefborough.—*ib.*

BURKE, a townfhip in Caledonia co. in Vermont; diftant from Bennington, 134 miles N. E.—*ib.*

BURLINGTON, is a pleafant townfhip, the chief in Chittendon co. Vermont, fituated on the S. fide of Onion River, on the E. bank of Lake Champlain. It has 332 inhabitants. It is in this healthy and agreeable fituation, that the governor and patrons of the college of Vermont, intend to found a feminary of learning, where youth of all denominations may receive an education.

In digging a well about 15 rods from the bank of the river, frogs have been found, at the depth of 25 feet, where no cavities or communication with the water appeared, through which they might have paffed; and when expofed to the heat of the fun they became full of life and activity. Here ftumps of trees are found 40 feet deep. It is conjectured that thefe animals muft have been covered up fome hundred years ago, by fome inundation of the river. Burlington is 22 miles northerly of Vergennes, 122 from Bennington, and 332 in the fame direction from New-York city, N. lat. 44. 30.—*ib.*

BURLINGTON, or *Ouineafkea Bay*, on the E. fide of Lake Champlain, about 34 miles N. by E. from Crown Point,

Point, 69 S. E. from Lake St Francis in St Lawrence River, and 70 foutherly from St John's. N. lat. 44. 22.—*ib.*

Burlington *Co.* in New-Jerfey, extends acrofs from the Atlantic ocean on the S. E. to Delaware River, and part of Huntingdon co. on the N. W. in length about 60 miles. A great proportion of it is barren; about ⅛ths of it, however, is under good cultivation, and is generally level, and is pretty well watered. It has 18,095 inhabitants, including 227 flaves.—*ib.*

Burlington, city, the chief town of the above co. is under the government of a mayor, aldermen, and common council. The extent of the townfhip is 3 miles along the Delaware, and a mile back; being about 18 miles N. E. of Philadelphia, and 11 from Trenton. The ifland, which is the moft populous part, is about a mile each way. It has 4 entrances over bridges, and caufeways, and a quantity of bank meadow adjoining. On the ifland are about 160 houfes, 1000 white, and 140 black inhabitants; few of the laft are flaves. The main ftreets are conveniently fpacious, and moftly ornamented with rows of trees. The town is oppofite Briftol in Pennfylvania, where the river is about a mile wide. Under the fhelter of Mittinicunk and Burlington iflands, is a fafe harbor, commodioufly fituated for trade; but too near the opulent city of Philadelphia to admit of any confiderable increafe of foreign commerce. Burlington was firft fettled in 1677, and has an academy and free fchool. Mittinicunk Ifland belongs to the latter, and yields a yearly profit of £180. Burlington has a place of public worfhip for the Friends, and another for the Epifcopalians; the former denomination of chriftians are the moft numerous. Here is a market houfe and the beft goal in the ftate, excepting the new ftate prifon near Trenton. There is likewife a nail manufactory, and an excellent diftillery. N. lat. 40. 8.—*ib.*

Burlington, a townfhip on the eaftern fide of Unadilla River, in Otfego co. New-York, is 11 miles W. of Cooperftown. By the ftate cenfus of 1796, 438 of its inhabitants are electors.—*ib.*

BURNS (Robert), was a native of Ayrfhire, one of the weftern counties of Scotland. He was the fon of humble parents; and his father paffed through life in the condition of a hired labourer, or of a fmall farmer. Even in this fituation, however, it was not hard for him to fend his children to the parifh fchool, to receive the ordinary inftruction in reading, writing, arithmetic, and the principles of religion. By this courfe of education young Robert profited to a degree that might have encouraged his friends to deftine him to one of the liberal profeffions, had not his father's poverty made it neceffary to remove him from fchool, as foon as he had grown up, to earn for himfelf the means of fupport as a hired ploughboy or fhepherd.

The expence of education in the parifh-fchools of Scotland is fo fmall, that hardly any parents who are able to labour want the means of giving to their children at leaft fuch education as young Burns received. From the fpring labours of a ploughboy, from the fummer employment of a fhepherd, the peafant-youth often returns for a few months, eagerly to purfue his education at the parifh-fchool.

It was fo with Burns; he returned from labour to learning, and from learning went again to labour, till his mind began to open to the charms of tafte and knowledge; till he began to feel a paffion for books, and for the fubjects of books, which was to give a colour to the whole thread of his future life. On nature he foon began to gaze with new difcernment and with new enthufiafm: his mind's eye opened to perceive affecting beauty and fublimity, where, by the mere grofs peafant, there was nought to be feen but water, earth, and fky—but animals, plants, and foil.

What might perhaps firft contribute to difpofe his mind to poetical efforts is one particular in the devotional piety of the Scottifh peafantry; it is ftill common for them to make their children get by heart the Pfalms of David, in that verfion of homely rhymes which is ufed in their churches. In the morning and in the evening of every day, or at leaft on the evening of every Saturday and Sunday, thefe Pfalms are fung in folemn family-devotion, a chapter of the Bible is read, and extemporary prayer is fervently uttered. The whole books of the Sacred Scriptures are thus continually in the hands of almoft every peafant. And it is impoffible that there fhould not be occafionally fome fouls among them, awakened to the divine emotions of genius by that rich affemblage which thofe books prefent, of almoft all that is interefting in incidents, or picturefque in imagery, or affectingly fublime or tender in fentiments and character. It is impoffible that thofe rude rhymes, and the fimple artlefs mufic with which they are accompanied, fhould not occafionally excite fome ear to a fond perception of the melody of verfe. That Burns had felt thefe impulfes, will appear undeniably certain to whoever fhall carefully perufe his *Cottar's Saturday's Night;* or fhall remark, with nice obfervation, the various fragments of Scripture fentiment, of Scripture imagery, of Scripture language, which are fcattered throughout his works.

Still more interefting to the young peafantry are thofe ancient ballads of love and war, of which a great number are, in the fouth of Scotland, yet popularly known, and often fung by the ruftic maid or matron at her fpinning-wheel. They are liftened to with ravifhed ears by old and young. Their rude melody; that mingled curiofity and awe which are naturally excited by the very idea of their antiquity; the exquifitely tender and natural complaints fometimes poured forth in them; the gallant deeds of knightly heroifm, which they fometimes celebrate; their wild tales of demons, ghofts, and fairies, in whofe exiftence fuperftition alone has believed; the manners which they reprefent; the abfolute yet picturefque and expreffive, language in which they are often clothed—give them wonderful power to tranfport every imagination, and to agitate every heart. To the foul of Burns they were like a happy breeze touching the wires of an Æolian harp, and calling forth the moft ravifhing melody.

Befide all this, the Gentle Shepherd, and the other poems of Allan Ramfay, have long been highly popular in Scotland. They fell early into the hands of Burns; and while the fond applaufe which they received drew his emulation, they prefented to him likewife treafures of phrafeology and models of verfification. He got acquainted at the fame time with the poetry of Robert Fergufon, written chiefly in the Scottifh dialect, and exhibiting many fpecimens of uncommon poetical excellence. The Seafons of Thomfon too,

too, the Grave of Blair, the far-famed Elegy of Gray, the Paradife Loft of Milton, perhaps the Minftrel of Beattie, were fo commonly read, even among thofe with whom Burns would naturally affociate, that poetical curiofity, although even lefs ardent than his, could in fuch circumftances have little difficulty in procuring them.

With fuch means to give his imagination a poetical bias, and to favour the culture of his tafte and genius, Burns gradually became a poet. He was not, however, one of thofe forward children who, from a miftaken impulfe, begin prematurely to write and to rhyme, and hence never attain to excellence. Converfing familiarly for a long while with the works of thofe poets who were known to him; contemplating the afpect of nature in a diftrict which exhibits an uncommon affemblage of the beautiful and the ruggedly grand, of the cultivated and the wild; looking upon human life with an eye quick and keen, to remark as well the ftronger and leading, as the nicer and fubordinate, features of character; to difcriminate the generous, the honourable, the manly, in conduct, from the ridiculous, the bafe, and the mean—he was diftinguifhed among his fellows for extraordinary intelligence, good fenfe, and penetration, long before others, or perhaps even himfelf, fufpected him to be capable of writing verfes. His mind was mature, and well ftored with fuch knowledge as lay within his fearch: he had made himfelf mafter of powers of language, fuperior to thofe of almoft any former writer in the Scottifh dialect, before he conceived the idea of furpaffing Ramfay and Fergufon.

Hitherto he had converfed intimately only with peafants on his own level; but having got admiffion into the fraternity of free-mafons, he had the fortune, whether good or bad, to attract in the lodges the notice of gentlemen better qualified than his more youthful companions to call forth the powers of his mind, and to fhow him that he was indeed a poet. A mafonic fong, a fatirical epigram, a rhyming epiftle to a friend, attempted with fuccefs, taught him to know his own powers, and gave him confidence to try tafks more arduous, and which fhould command ftill higher burfts of applaufe.

The annual celebration of the facrament of the Lord's Supper, in the rural parifhes of Scotland, has much in it of thofe old popifh feftivals, in which fuperftition, traffic, and amufement, ufed to be ftrangely intermingled. Burns faw, and feized in it one of the happieft of all fubjects, to afford fcope for the difplay of that ftrong and piercing fagacity by which he could almoft intuitively diftinguifh the reafonable from the abfurd, and the becoming from the ridiculous; of that picturefque power of fancy, which enabled him to reprefent fcenes, and perfons, and groupes, and looks, attitude, and geftures, in a manner almoft as lively and impreffive, even in words, as if all the artifices and energies of the pencil had been employed; of that knowledge which he had neceffarily acquired of the manners, paffions, and prejudices of the ruftics around him, of whatever was ridiculous, no lefs than of whatever was affectingly beautiful in rural life.

A thoufand prejudices of Popifh, and perhaps too of ruder Pagan fuperftition, have from time immemorial been connected in the minds of the Scottifh peafantry, with the annual recurrence of the Eve of the Feftival of all the Saints or Halloween. Thefe were all intimately known to Burns, and had made a powerful impreffion upon his imagination and feelings. He chofe them for the fubject of a poem, and produced a piece which is almoft to frenzy the delight of thofe who are beft acquainted with its fubject; and which will not fail to preferve the memory of the prejudices and ufages which it defcribes, when they fhall perhaps have ceafed to give one merry evening in the year to the cottage firefide.

The fimple joys, the honeft love, the fincere friendfhip, the ardent devotion of the cottage; whatever in the more folemn part of the ruftic's life is humble and artlefs, without being mean or unfeemly—or tender and dignified, without afpiring to ftilted grandeur—or to unnatural, bufkined pathos, had deeply impreffed the imagination of the rifing poet; had, in fome fort, wrought itfelf into the very texture of the fibres of his foul. He tried to exprefs in verfe what he moft tenderly felt, what he moft enthufiaftically imagined; and produced the *Cottar's Saturday's Night*.

Thefe pieces, the true effufions of genius, informed by reading and obfervation, and prompted by its own native ardour, as well as by friendly applaufe, were foon handed about among the moft difcerning of Burns's acquaintance; and were by every new reader perufed and reperufed, with an eagernefs of delight and approbation which would not fuffer their author long to withhold them from the prefs. A fubfcription was propofed, was earneftly promoted by fome gentlemen, who were glad to intereft themfelves in behalf of fuch fignal poetical merit; was foon crowded with the names of a confiderable number of the inhabitants of Ayrfhire, who in the proffered purchafe fought not lefs to gratify their own paffion for Scottifh poefy, than to encourage the wonderful ploughman. At Kilmarnock were the poems of Burns for the firft time printed. The whole edition was quickly diftributed over the country.

It is hardly poffible to exprefs with what eager admiration and delight they were every where received.—They eminently poffeffed all thofe qualities which the moft invariably contribute to render any literary work quickly and permanently popular. They were written in a phrafeology, of which all the powers were univerfally felt; and which being at once antique, familiar, and now rarely written, was hence fitted to ferve all the dignified and picturefque ufes of poetry, without making it unintelligible. The imagery, the fentiments, were at once faithfully natural, and irrefiftibly impreffive and interefting. Thofe topics of fatire and fcandal in which the ruftic delights; that humorous imitation of character, and that witty affociation of ideas familiar and ftriking, yet not naturally allied to one another, which has force to fhake his fides with laughter; thofe fancies of fuperftition, at which he ftill wonders and trembles; thofe affecting fentiments and images of true religion, which are at once dear and awful to his heart, were all reprefented by Burns with all a poet's magic power. Old and young, high and low, grave and gay, learned or ignorant, all were alike delighted, agitated, tranfported.

In the mean time, fome few copies of thefe fafcinating poems found their way to Edinburgh; and having been read to Dr Blacklock, they obtained his warmeft approbation. In the beginning of the winter 1786-7 Burns

Burns. Burns went to Edinburgh, where he was received by Dr Blacklock with the most flattering kindness, and introduced to every man of generosity and taste among that good man's friends. Multitudes now vied with each other in patronizing the rustic poet. Those who possessed at once true taste and ardent philanthrophy were soon earnestly united in his praise; they who were disposed to favour any good thing belonging to Scotland, purely because it was Scottish, gladly joined the cry; those who had hearts and understanding to be charmed, without knowing why, when they saw their native customs, manners, and language, made the subjects and the materials of poesy, could not suppress that voice of feeling which struggled to declare itself for Burns: for the dissipated, the licentious, the malignant wits, and the freethinkers, he was so unfortunate as to have satire, and obscenity, and ridicule of things sacred, sufficient to captivate their fancies; even for the pious he had passages in which the inspired language of devotion might seem to come mended from his pen.

Thus did Burns, ere he had been many weeks in Edinburgh, find himself the object of universal curiosity, favour, admiration, and fondness. He was sought after, courted with attentions the most respectful and assiduous, feasted, flattered, caressed, treated by all ranks as the first boast of his country, whom it was scarcely possible to honour and reward to a degree equal to his merits. In comparison with the general favour which now promised to more than crown his most sanguine hopes, it could hardly be called praise at all which he had obtained in Ayrshire.

In this posture of our poet's affairs a new edition of his poems was earnestly called for. He sold the copyright for one hundred pounds; but his friends at the same time suggested, and actively promoted a subscription for an edition, to be published for the benefit of the author, ere the bookseller's right should commence. Those gentlemen who had formerly entertained the public of Edinburgh with the periodical publication of the papers of the *Mirror*, having again combined their talents in producing the *Lounger*, were at this time about to conclude this last series of papers; yet before the Lounger relinquished his pen, he dedicated a number to a commendatory criticism of the poems of the Ayrshire bard.

The subscription-papers were rapidly filled; and it was supposed that the poet might derive from the subscription and the sale of his copy-right a clear profit of at least 700 pounds.

The conversation of even the most eminent authors is often found to be so unequal to the fame of their writings, that he who reads with admiration can listen with none but sentiments of the most profound contempt. But the conversation of Burns was in comparison with the formal and exterior circumstances of his education, perhaps even more wonderful than his poetry. He affected no soft air or graceful motions of politeness, which might have ill accorded with the rustic plainness of his native manners. Conscious superiority of mind taught him to associate with the great, the learned, and the gay, without being overawed into any such bashfulness as might have made him confused in thought, or hesitating in elocution. He possessed withal an extraordinary share of plain common sense or mother-wit, which prevented him from obtruding upon persons, of whatever rank with whom he was admitted to converse, any of those effusions of vanity, envy, or self-conceit, in which authors are exceedingly apt to indulge, who have lived remote from the general practice of life, and whose minds have been almost exclusively confined to contemplate their own studies and their own works. In conversation he displayed a sort of intuitive quickness and rectitude of judgment upon every subject that arose. The sensibility of his heart, and the vivacity of his fancy, gave a rich colouring to whatever reasoning he was disposed to advance; and his language in conversation was not at all less happy than in his writings. For these reasons, those who had met and conversed with him once, were pleased to meet and to converse with him again and again.

For some time he conversed only with the virtuous, the learned, and the wise; and the purity of his morals remained uncontaminated. But, alas! he fell, as others have fallen in similar circumstances. He suffered himself to be surrounded by a race of miserable beings, who were proud to tell that they had been in company with Burns, and had seen Burns as loose and as foolish as themselves. He was not yet irrecoverably lost to temperance and moderation; but he was already almost too much captivated with their wanton rivals, to be ever more won back to a faithful attachment to their more sober charms. He now also began to contract something of new arrogance in conversation. Accustomed to be among his favourite associates what is vulgarly but expressively called *the cock of the company*, he could scarcely refrain from indulging in similar freedom and dictatorial decision of talk, even in the presence of persons who could less patiently endure his presumption.

The subscription edition of his poems, in the mean time, appeared; and although not enlarged beyond that which came from the Kilmarnock press by any new pieces of eminent merit, did not fail to give entire satisfaction to the subscribers. He was now to close accounts with his bookseller and his printer, to retire to the country with his profits in his pocket, and to fix upon a plan for his future life. He talked loudly of independence of spirit and simplicity of manners, and boasted his resolution to return to the plough; yet still he lingered in Edinburgh, week after week, and month after month, perhaps expecting that one or other of his noble patrons might procure him some permanent and competent annual income, which should set him above all necessity of future exertions to earn for himself the means of subsistence; perhaps unconsciously reluctant to quit the pleasures of that voluptuous town-life to which he had for some time too willingly accustomed himself. An accidental dislocation or fracture of an arm or a leg confining him for some weeks to his apartment, left him during this time leisure for serious reflection; and he determined to retire from the town without longer delay. None of all his patrons interposed to divert him from his purpose of returning to the plough, by the offer of any small pension, or any sinecure place of moderate emolument, such as might have given him competence without withdrawing him from his poetical studies. It seemed to be forgotten that a ploughman thus exalted into a man of letters was unfitted for his former toils, without being regularly qualified to enter the career of any new profession; and that it became incumbent

cumbent upon thofe patrons who had called him from the plough, not merely to make him their companion in the hour of riot, not fimply to fill his purfe with gold for a few tranfient expences, but to fecure him as far as was poffible from being ever overwhelmed in diftrefs in confequence of the favour which they had fhown him, and of the habits of life into which they had feduced him. Perhaps indeed the fame delufion of fancy betrayed both Burns and his patrons into the miftaken idea, that, after all which had paffed, it was ftill poffible for him to return in cheerful content to the homely joys and fimple toils of undiffipated rural life.

In this temper of Burns's mind, in this ftate of his fortune, a farm and the excife were the objects upon which his choice ultimately fixed for future employment and fupport. By the furgeon who attended him during his illnefs, he was recommended with effect to the commiffioners of excife; and Patrick Millar, Efq; of Dalfwinton, deceived, like Burns himfelf and Burns's other friends, into an idea that the poet and exciseman might yet be refpectable and happy as a farmer, generoufly propofed to eftablifh him in a farm, upon conditions of leafe which prudence and induftry might eafily render exceedingly advantageous. Burns eagerly accepted the offers of this benevolent patron. Two of the poet's friends from Ayrfhire were invited to furvey that farm in Dumfriesfhire which Mr Millar offered. A leafe was granted to the poetical farmer at that annual rent which his own friends declared that the due cultivation of his farm might eafily enable him to pay. What yet remained of the profits of his publication was laid out in the purchafe of farm-ftock; and Mr Millar might, for fome fhort time, pleafe himfelf with the perfuafion that he had approved himfelf the liberal patron of genius; had acquired a good tenant upon his eftate; and had placed a deferving man in the very fituation in which alone he himfelf defired to be placed, in order to be happy to his wifhes.

Burns, with his Jane, whom he now married, took up their refidence upon his farm. The neighbouring farmers and gentlemen, pleafed to obtain for an inmate among them the poet by whofe works they had been delighted, kindly fought his company, and invited him to their houfes. He found an inexpreffible charm in fitting down befide his wife, at his own firefide; in wandering over his own grounds; in once more putting his hand to the fpade and the plough; in forming his inclofures, and managing his cattle. For fome months he felt almoft all that felicity which fancy had taught him to expect in his new fituation. He had been for a time idle; but his mufcles were not yet unbraced for rural toil. He now feemed to find a joy in being the hufband of the miftrefs of his affections, in feeing himfelf the father of her children, fuch as might promife to attach him for ever to that modeft, humble, and domeftic life, in which alone he could hope to be permanently happy. Even his engagements in the fervice of the excife did not, at the very firft, threaten neceffarily to debafe him by affociation with the mean, the grofs, and the profligate, to contaminate the poet, or to ruin the farmer.

But it could not be: it was not poffible for Burns now to affume that fobernefs of fancy and paffions, that fedatenefs of feeling, thofe habits of earneft attention to grofs and vulgar cares, without which fuccefs in his new fituation was not to be expected. A thoufand difficulties were to be encountered and overcome, much money was to be expended, much weary toil was to be exercifed, before his farm could be brought into a ftate of cultivation, in which its produce might enrich the occupier. This was not a profpect encouraging to a man who had never loved labour, and who was at this time certainly not at all difpofed to enter into agriculture with the enthufiafm of a projector. The bufinefs of the excife too, as he began to be more and more employed in it, diftracted his mind from the care of his farm, led him into grofs and vulgar fociety, and expofed him to many unavoidable temptations to drunken excefs, fuch as he had no longer fufficient fortitude to refift. Amidft the anxieties, diftractions, and feducements which thus arofe to him, home became infenfibly lefs and lefs pleafing; even the endearments of his Jane's affection began to lofe their hold on his heart; he became every day lefs and lefs unwilling to forget in riot thofe gathering forrows which he knew not to fubdue.

Mr Millar and fome others of his friends would gladly have exerted an influence over his mind which might have preferved him in this fituation of his affairs, equally from defpondency and from diffipation; but Burns's temper fpurned all controul from his fuperiors in fortune. He refented, as an arrogant encroachment upon his independence, that tenor of conduct by which Mr Millar wifhed to turn him from diffolute conviviality, to that fteady attention to the bufinefs of his farm, without which it was impoffible to thrive in it. His croffes and difappointments drove him every day more and more into diffipation; and his diffipation tended to enhance whatever was difagreeable and perplexing in the ftate of his affairs. He funk, by degrees, into the boon companion of mere excifemen; and almoft every drunken fellow, who was willing to fpend his money lavifhly in the alehoufe, could eafily command the company of Burns. The care of his farm was thus neglected; wafte and loffes wholly confumed his little capital; he refigned his leafe into the hands of his landlord; and retired, with his family, to the town of Dumfries, determining to depend entirely for the means of future fupport upon his income as an excife-officer.

Yet during this unfortunate period of his life, which paffed between his departure from Edinburgh to fettle in Dumfriesfhire, and his leaving the country in order to take up his refidence in the town of Dumfries, the energy and activity of his intellectual powers appeared to have been not at all impaired. In a collection of Scottifh fongs, which were publifhed (the words with the mufic) by Mr Johnfon, engraver in Edinburgh, in 4 vols 8vo, Burns, in many inftances, accommodated new verfes to the old tunes with admirable felicity and fkill. He affifted in the temporary inftitution of a fmall fubfcription library, for the ufe of a number of the well-difpofed peafants in his neighbourhood. He readily aided, and by his knowledge of genuine Scottifh phrafeology and manners greatly enlightened, the antiquarian refearches of the late ingenious Captain Grofe. He ftill carried on an epiftolary correfpondence, fometimes gay, fportive, humorous, but always enlivened by bright flafhes of genius, with a number of his old friends, and on a very wide diverfity of topics. At times, as it fhould feem from his writings of this period, he reflected, with inexpreffible heart-bitternefs, on the

high

high hopes from which he had fallen; on the errors of moral conduct into which he had been hurried by the ardour of his ſoul; and in ſome meaſure by the very generoſity of his nature; on the diſgrace and wretchedneſs into which he ſaw himſelf rapidly ſinking; on the ſorrow with which his miſconduct oppreſſed the heart of his Jane; on the want and deſtitute miſery in which it ſeemed probable that he muſt leave her and their infants; nor amidſt theſe agonizing reflections did he fail to look, with an indignation half invidious, half contemptuous, on thoſe who, with moral habits not more excellent than his, with powers of intellect far inferior, yet baſked in the ſun-ſhine of fortune, and were loaded with the wealth and honours of the world, while his follies could not obtain pardon, nor his wants an honourable ſupply. His wit became from this time more gloomily ſarcaſtic; and his converſation and writings began to aſſume ſomething of a tone of miſanthropical malignity, by which they had not been before, in any eminent degree, diſtinguiſhed. But with all theſe failings, he was ſtill that exalted mind which had raiſed itſelf above the depreſſion of its original condition: with all the energy of the lion, pawing to ſet free his hinder limbs from the yet encumbering earth, he ſtill appeared *not leſs than archangel ruined!*

His morals were not mended by his removal from the country. In Dumfries his diſſipation became ſtill more deeply habitual; he was here more expoſed than in the country to be ſolicited to ſhare the riot of the diſſolute and the idle: fooliſh young men flocked eagerly about him, and from time to time preſſed him to drink with them, that they might enjoy his wicked wit. The Caledonian Club, too, and the Dumfriesſhire and Galloway Hunt, had occaſional meetings in Dumfries after Burns went to reſide there, and the poet was of courſe invited to ſhare their conviviality, and heſitated not to accept the invitation.

In the intervals between his different fits of intemperance, he ſuffered ſtill the keeneſt anguiſh of remorſe, and horribly afflictive foreſight. His Jane ſtill behaved with a degree of maternal and conjugal tenderneſs and prudence, which made him feel more bitterly the evil of his miſconduct, although they could not reclaim him. At laſt crippled, emaciated, having the very power of animation waſted by diſeaſe, quite broken-hearted by the ſenſe of his errors, and of the hopeleſs miſeries in which he ſaw himſelf and his family depreſſed; with his ſoul ſtill tremblingly alive to the ſenſe of ſhame, and to the love of virtue; yet even in the laſt feebleneſs, and amid the laſt agonies of expiring life, yielding readily to any temptation that offered the ſemblance of intemperate enjoyment, he died at Dumfries, in the ſummer of 1796, while he was yet three or four years under the age of forty, furniſhing a melancholy proof of the danger of *ſuddenly* elevating even the greateſt mind above its original level.

After his death it quickly appeared that his failings had not effaced from the minds of his more reſpectable acquaintance either the regard which had once been won by his ſocial qualities, or the reverence due to his intellectual talents. The circumſtances of want in which he left his family were noticed by the gentlemen of Dumfries with earneſt commiſeration. His funeral was celebrated by the care of his friends with a decent ſolemnity, and with a numerous attendance of mourners, ſufficiently honourable to his memory. Several copies of verſes were inſerted in different newſpapers upon the occaſion of his death. A contribution, by ſubſcription, was propoſed, for the purpoſe of raiſing a ſmall fund, for the decent ſupport of his widow, and the education of his infant children.

From the preceding detail of the particulars of this poet's life, the reader will naturally and juſtly infer him to have been an honeſt, proud, warm-hearted man; of high paſſions and ſound underſtanding, and a vigorous and excurſive imagination. He was never known to deſcend to any act of deliberate meanneſs. In Dumfries he retained many reſpectable friends even to the laſt; and it may be doubted whether any poet of the preſent age has exerciſed a greater power over the minds of his readers. Burns has not failed to command one remarkable ſort of homage, ſuch as is never paid but to great original genius; a crowd of poetaſters ſtarted up to imitate him, by writing verſes as he had done in the Scottiſh dialect; but, *O imitatores! ſervum pecus!* To write rugged rhymes, in antiquated phraſe, is not to imitate the poetry of Burns.

BURRAMPOOTER. See Sandpu, *Encycl.*

BUSHWICK, a ſmall, but pleaſant town, in King's co. Long Iſland, New-York. The inhabitants, 540 in number, are chiefly of Dutch extraction; 99 of theſe are electors.—*Morſe.*

BUTTER is a ſubſtance ſo well known, that it is needleſs to give here any definition of it. It is one of the three component parts of milk, the other two being *whey* and *cheeſe*. It is evident from the proceſſes by which butter and cheeſe are made, that theſe two parts are not completely diſſolved in the ſerum or whey, but only diffuſed through it like an emulſion. They may indeed be ſeparated from it by reſt alone, without any artificial preparation.

Butter, though uſed at preſent as food in moſt countries of Europe, was not known, or known very imperfectly, to the ancients. This, we think, is completely proved by Profeſſor Beckmann in the ſecond volume of his *Hiſtory of Inventions*. In our tranſlation of the Hebrew Scripture, there is indeed frequent mention made of butter at very early periods; but, as the Profeſſor well obſerves, the greateſt maſters of biblical criticiſm unanimouſly agree, that the word ſo tranſlated ſignifies milk or cream, or ſour thick milk, and cannot poſſibly mean what we call *butter*. The word plainly alludes to ſomething liquid which was uſed for waſhing the feet, which was drunk, and which had ſometimes the power of intoxicating; and we know that mare's milk may be ſo prepared as to produce the ſame effect. See Koumiss, *Encycl.*

The oldeſt mention of butter, the Profeſſor thinks, is in the account of the Scythians given by Herodotus (lib. iv. 2.), who ſays, that "theſe people pour the milk of their mares into wooden veſſels, cauſe it to be violently ſtirred or ſhaken by their blind ſlaves, and ſeparate the part which ariſes to the ſurface, as they conſider it as more valuable and delicious than what is collected below it." That this ſubſtance muſt have been a ſoft kind of butter, is well known; and Hippocrates gives a ſimilar account of Scythian butter, and calls it πικεριον, which Galen tranſlates by the word βουτυρον. The poet Anaxandrides, who lived ſoon after Hippocrates, deſcribing the marriage feaſt of Iphicrates, who married

married the daughter of Cotys king of Thrace, says, that the Thracians ate butter, which the Greeks at that time considered as a wonderful kind of food.

Dioscorides says, that good butter was prepared from the fattest milk, such as that of sheep or goats, by shaking it in a vessel till the fat was separated. To this butter he ascribes the same effects, when used externally, as those produced by our butter at present. He adds also, and he is the first writer who makes the observation, that fresh butter might be melted and poured over pulse and vegetables instead of oil, and that it might be employed in pastry in the room of other fat substances. A kind of soot likewise was at that time prepared from butter for external applications, which was used in curing inflammation of the eyes and other disorders. For this purpose the butter was put into a lamp, and when consumed the lamp was again filled till the desired quantity of soot was collected in a vessel placed over it.

Galen, who distinguishes and confirms in a more accurate manner the healing virtues of butter, expresly remarks, that cow's milk produces the fattest butter; that butter made from sheep's or goat's milk is less rich; and that ass's milk yields the poorest. He expresses his astonishment, therefore, that Dioscorides should say that butter was made from the milk of sheep and goats. He assures us that he had seen it made from cow's milk, and that he believes it had thence acquired its name. "Butter (says he) may be very properly employed for ointments; and when leather is besmeared with it, the same purpose is answered as when it is rubbed over with oil. In cold countries, which do not produce oil, butter is used in the baths; and that it is a real fat, may be readily perceived by its catching fire when poured over burning coals." What has been here said is sufficient to shew that butter must have been very little known to or used by the Greeks and the Romans in the time of Galen, that is, at the end of the second century.

The Professor having collected, in chronological order, every thing which he could find in the works of the ancients respecting butter, concludes, that it is not a Grecian, and much less a Roman, invention, but that the Greeks were made acquainted with it by the Scythians, the Thracians, and the Phrygians, and the Romans by the people of Germany. He is likewise decidedly of opinion, that when these two polished nations had learned the art of making it, they used it not as food, but only as an ointment, or sometimes as a medicine. "We never find it (says he) mentioned by Galen and others as a food, though they have spoken of it as applicable to other purposes. No notice is taken of it by Apicius; nor is there any thing said of it in that respect by the authors who treat on agriculture, though they have given us very particular information concerning milk, cheese, and oil."

The case, however, is now very different. It is, in this country at least, so general an article of food, that the proper methods of making and curing it have engaged the attention of some of our ablest writers on agriculture. In addition to what has been said on these subjects under the titles BUTTER and DAIRY *(Encyclopædia)*, our readers will probably be pleased with the following method of curing it, which is practised by some farmers in the parish of Udney, in the county of Aberdeen, and gives to their butter a great superiority above that of their neighbours.

Take two parts of the best common salt, one part of sugar, and one part of saltpetre; beat them up together, and blend the whole completely. Take one ounce of this composition for every sixteen ounces of butter, work it well into the mass, and close it up for use.

Dr James Anderson, from whose View of the Agriculture of the County of Aberdeen this receipt is taken, says, that he knows of no simple improvement in economics greater than this is, when compared with the usual mode of curing butter by means of common salt alone. "I have seen (continues he) the experiment fairly made, of one part of the butter made at one time being thus cured, and the other part cured with salt alone: the difference was inconceivable. I should suppose that, in any open market, the one would sell for 30 *per cent*, more than the other. The butter cured with the mixture appears of a rich marrowy consistence and fine colour, and never acquires a brittle hardness nor tastes salt; the other is comparatively hard and brittle, approaching more nearly to the appearance of tallow, and is much salter to the taste. I have ate butter cured with the above composition that had been kept three years, and it was as sweet as at first; but it must be noted, that butter thus cured requires to stand three weeks or a month before it is begun to be used. If it be sooner opened, the salts are not sufficiently blended with it; and sometimes the coolness of the nitre will then be perceived, which totally disappears afterwards."

The following observations respecting the proper method of keeping both milk and butter are by the same author, and we trust may prove useful. Speaking still of the county of Aberdeen, he says, "The pernicious practice of keeping milk in leaden vessels, and salting butter in stone jars, begins to gain ground among some of the fine ladies in this county, as well as elsewhere, from an idea of cleanliness. The fact is, it is just the reverse of cleanliness; for in the hands of a careful person nothing can be more cleanly than wooden dishes, but under the management of a slattern they discover the secret which stone dishes indeed do not.

"In return, these latter communicate to the butter and the milk, which has been kept in them, a poisonous quality, which inevitably proves destructive to the human constitution. To the prevalence of this practice I have no doubt we must attribute the frequency of palsies, which begin to prevail so much in this kingdom; for the well known effect of the poison of lead is bodily debility, palsy—death!"

BUTTERHILL, a high round hill, on the W. bank of Hudson river, at the northern entrance of the Highlands. In passing this hill, ascending the river, the passenger is presented with a charming view of New-Windsor and Newburgh.—*Morse.*

BUXTON, a township in York co. district of Maine, situated on Saco River; 16 miles N. westerly from Pepperelborough, at the mouth of that river, and 118 miles N. E. of Boston; containing 1564 inhabitants. —*ib.*

BYEFIELD, a parish in Newbury, Essex co. Massachusetts. In a quarry of lime stone here, is found the *asbestos*, or incorruptible cotton, as it is sometimes called.

 called. Beautifully variegated marble, which admits a good polish, has likewise been found in the same vicinity. Here is also a flourishing woollen manufactory established on a liberal scale; and machinery for cutting nails.—*ib.*

BYRD, FORT, lies on the eastern bank of Monongahela River; on the S. side of the mouth of Red-Stone Creek; 35 miles S. from Pittsburg, and about 29 N. W. from Ohiopyle Falls. On or near this spot stands the compact part of the town of Brownsville. N. lat. 39. 58. W. long. 81. 12.—*ib.*

BYSAK, the first month of the Bengal year, beginning in April.

C.

CABARRUS, a new county in the district of Salisbury, North-Carolina.—*Morse.*

CABIN *Point*, a small post-town in Surry co. Virginia, situated on Upper Chipoak creek, 26 miles E. S. E. of Petersburg, 87 from Portsmouth, and 329 S. S. W. of Philadelphia. N. lat. 37.—*ib.*

CACAPEHON, a river of Virginia, which runs about 70 miles N. easterly along the western side of North Ridge, and empties into Potowmack River, 30 miles N. from Frederickstown.—*ib.*

CADIZ, a town on the N. side of the island of Cuba, near 160 miles E. of Havannah, and 50 N. from Spiritu Santo.—*ib.*

CÆSARIA *River*, or *Cohansie Creek*, in New-Jersey, empties into Delaware Bay, after a S. westerly course of about 30 miles. It is navigable for vessels of 100 tons as far as Bridgetown, 20 miles from its mouth.—*ib.*

CAFFRES, the inhabitants of Caffraria, are generally confounded with the Hottentots; but, according to M. Vaillant, there is a considerable difference between the manners, customs, and even appearance of these two nations.

The Caffres, says he, are generally taller than the Hottentots, more robust, more fierce, and much bolder. Their figure is likewise more agreeable, and their countenances have not that narrowness at the bottom, nor their cheeks those prominences, which are so disagreeable among the Hottentots. A round figure, a nose not too flat, a broad forehead, and large eyes, give them an open and lively air; and if prejudice can overlook the colour of the skin, there are some Caffre women who, even in Europe, would be accounted pretty. These people do not make their faces ridiculous, by pulling out their eye-brows like the Hottentots; they tattoo themselves much, and particularly their bodies; their hair, which is frizzled very much, is never greased, but their bodies are liberally anointed, merely with a view to preserve their vigour and agility.

The men generally bestow more attention on their dress than the women, and are remarkably fond of beads and copper rings. The women wear hardly any of the ornaments in which the other savages in Africa take such delight. They do not even wear copper bracelets; but their small aprons, which are still shorter than those of the Hottentots, are bordered with a few rows of glass-beads; and in this all their luxury consists. It would appear that the Caffres are not so chaste as the Hottentots, because the men do not use a jackal to vail what nature teaches other men, even savages, to conceal. A small cowl, which covers only the glans, instead of displaying modesty, seems to announce the greatest indecency. This small covering adheres to a thong, which is fastened round their girdles, merely that it may not be lost; for a Caffre, if he be not afraid of being hurt or stung by insects, cares very little whether his cowl be in its place or not. Our author saw one Caffre, who, instead of a cowl, wore a case made of wood, and ornamented with sculpture. This was a new and ridiculous fashion, which he had borrowed from a nation of black people who lived at a great distance from Caffraria.

In the hot season the Caffres go always naked, and retain nothing but their ornaments. In cold weather they wear krosses made of calves or oxen's hides, which reach down to the ground; but whatever the weather be, both sexes go bare-headed, except that they sometimes, though rarely, fix a plume of feathers in their hair.

The Caffre huts are more spacious and higher than those of the Hottentots, and have also a more regular form. The frames of them are constructed of wooden work, well put together, and very solid, being intended to last for a long time: for the Caffres, applying to agriculture, which the free Hottentots do not, remain fixed to one spot, unless something unexpected interrupt their repose.

A more perceptible industry, an acquaintance with some of the most necessary arts of life, a little knowledge of agriculture, and a few religious dogmas, seem to announce that the Caffres approach much nearer to civilization than the Hottentots. They entertain a tolerably exalted idea of the Supreme Being and his power; they believe that the good will be rewarded, and the wicked punished, in a future state; but they have no notion of creation, which indeed was not admitted by the sages of Greece and Rome. They practise circumcision, but can give no account of its origin among them, or of the purpose for which the practice is continued.

Polygamy is used among the Caffres; and on the death of a father the male children and their mothers share the succession among them. The girls remain with

with their mothers without property of any kind until they can procure husbands. One very singular custom of the Caffres is, that they do not, in general, inter their dead, but transport them from the kraal to an open ditch, which is common to the whole horde. At this ditch savage animals feed at their leisure on the multitude of carcases which are heaped together. Funeral honours are due only to kings and the chiefs of each horde, whose bodies are covered with a heap of stones collected into the form of a dome.

This nation is governed by a general, chief, or king, whose power is very limited. He appoints, however, the subordinate chiefs over the different hordes, and through them communicates his directions or orders. The arms of the Caffre are a *club*, two feet and a half in length, and where thickest three inches in diameter, and a plain lance or *assagey*. He despises poisoned arrows, which are so much used by some of the neighbouring nations; and with his two simple weapons seeks always to meet his enemy face to face in the field. The Hottentot, on the contrary, concealed under a rock or behind a bush, deals out destruction, without being exposed to danger. The one is a perfidious tyger, which rushes treacherously on his prey; the other is a generous lion, which, having given warning of his approach, makes his attack boldly, and perishes if he prevail not against his antagonist.

CAGHNEWAGA, a tribe of Indians in Lower Canada, some of whom inhabit near Montreal.—*Morse.*

CALCAYLARES, a jurisdiction in S. America, and empire of Peru, subject to the bishop of Cusco, about 4 leagues W. of that city; exuberant in all kinds of grain and fruits, and sugar equal to any of the refined sugar of Europe. Formerly it produced 80,000 arobas; but the quantity is now said to be much less. —*ib.*

CALCULUS, in mathematics, denotes a certain way of performing investigations and resolutions, which occur on many occasions, particularly in mechanical philosophy. Thus we say, the *antecedental* calculus, the *algebraical* calculus, the *arithmetical* calculus, the *differential* calculus, the *exponential* calculus, the *fluxional* calculus, and the *integral* calculus. Of by much the greater part of these calculi some account has been given in the Encyclopædia; but there is one of them, of which no notice has been taken in that work. It is,

The Antecedental CALCULUS, a geometrical method of reasoning, without any consideration of motion or velocity, applicable to every purpose to which the much celebrated doctrine of fluxions of the illustrious Newton has been, or can be, applied. This method was invented by James Glenie, Esq; "in which (he says) every expression is truly and strictly geometrical, is founded on principles frequently made use of by the ancient geometers, principles admitted into the very first elements of geometry, and repeatedly used by EUCLID himself. As it is a branch of general geometrical proportion, or universal comparison, and is derived from an examination of the antecedents of ratios, having given consequents and a given standard of comparison in the various degrees of augmentation and diminution they undergo by composition and decomposition, I have called it the antecedental calculus. As it is purely geometrical, and perfectly scientific, I have, since it first occurred to me in 1779, always made use of it instead of the fluxionary and differential calculi, which are merely arithmetical. Its principles are totally unconnected with the ideas of motion and time, which, strictly speaking, are foreign to pure geometry and abstract science, though, in mixed mathematics and natural philosophy, they are equally applicable to every investigation, involving the consideration of either with the two numerical methods just mentioned. And as many such investigations require compositions and decompositions of ratios, extending greatly beyond the triplicate and subtriplicate, this calculus in all of them furnishes every expression in a strictly geometrical form. The standards of comparison in it may be any magnitudes whatever, and are of course indefinite and innumerable; and the consequents of the ratios, compounded or decompounded, may be either equal or unequal, homogeneous or heterogeneous. In the fluxionary and differential methods, on the other hand, 1, or unit, is not only the standard of comparison, but also the consequent of every ratio compounded or decompounded."

This method is deduced immediately from Mr Glenie's Treatise on the Doctrine of Universal Comparison or General Proportion: And as the limits of the present work will not allow us to enter upon this subject, we therefore refer our readers to the two above mentioned treatises, and to the fourth volume of the Transactions of the Royal Society of Edinburgh.

We confess, however, that we do not expect such great advantage from the employment of this calculus as the very acute and ingenious author seems to promise from it. The mathematical world is truly indebted to him for the clear and discriminating view that he has taken of the doctrine of universal comparison, and we believe it to be perfectly accurate, and in some respects new. Notwithstanding the continual occupation of mathematicians with ratios and analogies, their particular objects commonly restricted their manner of conceiving ratio to some present modification of it. Hence it seems to have happened that their conceptions of it as a magnitude have not been uniform. But Mr Glenie, by avoiding every peculiarity, has at once attributed to it all the measurable affections of magnitude, addition or subtraction, multiplication or division, and ratio or proportion. He is perhaps the first who has roundly considered ratio or proportion as an affection of ratio; and it is chiefly by the employment of this undoubted affection of ratio that he has rendered the geometrical analysis so comprehensive.

But when we view this antecedental calculus, not as a method of expressing mathematical science, but as an art, as a calculus in short, and consider the means which it must employ, and the notations which must be used, we become less sanguine in our hopes of advantage from it. The notation cannot (we think) be more simple than that of the fluxionary method, justly called *arithmetical;* and if we insist on carrying clear conceptions along with us, we imagine that the arithmetical exposition of our symbols will generally be the simpler of the two. The *science* of the antecedental calculus seems to consist in the attainable perception of all the simple ratios, whether of *magnitudes*, or *ratios*, or both, which concur to the formation of a compound and complicated ratio. Now this is equally, and more easily, attainable in the fluxionary or other arithmetical method, when the consequent is a simple magnitude. When it is not, the fame procefs is farther neceffary in both methods, for getting rid of its complication.

We apprehend that it is a miftake that the geometrical method is more abftracted than the fluxionary, becaufe the latter fuperadds to the notion of extenfion the notions of time and motion. Thefe notions were introduced by the illuftrious inventor *for the demonftration*, but never occupy the thoughts *in the ufe* of his propofitions. Thefe are *geometrical* truths, no matter how demonftrated; and when duly confidered, involve nothing that is omitted in the antecedental calculus. We even prefume to fay, that the complication of thought, in the contemplation of the ratios of ratios, is greater than what will generally arife from the additional elements, time and motion.

We do not find that any of our moft active mathematicians have availed themfelves of the advantages of this calculus, nor do we know any fpecimen that has been exhibited of its eminent advantages in mathematical difcuffions. Should it prove more fertile in geometrical expreffions of highly compounded or complicated quantities or relations, we fhould think it a mighty acquifition; being fully convinced that thefe afford to the memory or imagination an object (we may call it a fenfible picture) which it can contemplate and remember with incomparably greater clearnefs and fteadinefs than any algebraical formula. We need only appeal to the geometrical expreffions of many fluents, which are to be feen in Newton's lunar theory, in the phyfical tracts of Dr Matthew Stewart, and others who have fhewn a partiality for this method.

It would be very prefumptuous, however, for us to fay, that the accurate geometer and metaphyfician may not derive great advantages from profecuting the very ingenious and recondite fpeculations of Mr Glenie, in his doctrine of univerfal comparifon.

CALEDONIA *Co.* in Vermont, contains 24 townfhips and has Connecticut river S. E.; Orleans and Chittenden counties N. W.; Effex co. N. E.; and Orange co. of which, until lately, it formed a part, S. W.—*Morse.*

Caledonia, a port on the ifthmus of Darien, in the N. Sea, 25 leagues N. W. from the river Atrato. It was attempted to be eftablifhed by the Scotch nation in 1698, and had at firft all the promifing appearances of fuccefs; but the Englifh, influenced by narrow national prejudices, put every impediment in their way; which, joined to the unhealthinefs of the climate, deftroyed the infant colony.—*ib.*

CALENDAR, in chronology. See *(Encycl.)* Kalendar; and Revolution, n° 184.

CALI, a city of New Granada, S. America, fituated on the river Cauca. The ftaple port for this city, as alfo for thofe of Popayan, Santa Fe, and the fouthern parts of Terra Firma, is Bonaventura in the diftrict of Popayan. The road by land from that port is not paffable for beafts of burden; fo that travellers, with their baggage, are carried on the backs of Indians in a chair, with which weight they crofs rivers and mountains, being entirely flaves to the Spaniards, who thus fubftitute them in the room of horfes and mules. N. lat. 3. 15. W. long. 76. 30.—*Morse.*

CALIPPIC period, in chronology, a period of 76 years, continually recurring; at every repetition of which, it was fuppofed by its inventor Calippus, an Athenian aftronomer, that the mean new and full moons would always return to the fame day and hour.

About a century before, the golden number, or cycle of 19 years, had been invented by Meton; which Calippus finding to contain 19 of Nabonaffar's year, 4 days, and $\frac{3}{4}\frac{1}{7}\frac{1}{9}$, to avoid fractions he quadrupled it, and fo produced his period of 76 years, or 4 times 19; after which he fuppofed all the lunations, &c. would regularly return to the fame hour. But neither is this exact, as it brings them too late by a whole day in 225 years.

CALLAO, as it is called by its inhabitants, but more generally known to Europeans under the name of Campello, is a fmall ifland, which was vifited by fome of Lord Macartney's fuite on their voyage to China. In confequence of that vifit, we have the following defcription of it in Sir George Staunton's Account of the Embaffy.

" It lies oppofite to, and about eight miles to the eaftward of, the mouth of a confiderable river on the coaft of Cochin-china, on the banks of which is fituated the town of Fai-foo, a place of fome note, not far from the harbour of Turon. The bearing of the higheft peak of Callao from this harbour is about fouth-eaft, diftance thirty miles. The extreme points of the ifland lie in latitude 15° 53′, and 15° 57′ north; the greateft length is from north-weft to fouth-eaft, and is fomewhat about five miles, and the mean breadth two miles. The only inhabited part is on the fouth-weft coaft, on a flip of ground rifing gently to the eaft, and contained between the bottom of a femilunar bay and the mountains on each fide of it. Thofe mountains, at a diftance, appear as if they formed two diftinct iflands. The fouthern mountain is the higheft, and is about 1500 feet. The lower grounds contain about 200 acres. This fmall but enchanting fpot is beautifully diverfified with neat houfes, temples, clumps of trees, fmall hillocks fwelling from the plain, and richly decorated with fhrubbery and trees of various kinds; among which the elegant areca, rifing like a Corinthian column, is eminently confpicuous. A rill of clear water, oozing from the mountains, is contrived to be carried along the upper ridges of the vale, from whence it is occafionally conveyed through fluices, for the purpofe of watering the rice grounds, and appeared, though then in the dry feafon, fully fufficient for every purpofe for which it could be wanted.

" The houfes, in general, were clean and decent; a few were built with ftone, and covered with tiles. One, probably the manfion of the chief perfon of the ifland, was inclofed by a ftone wall, and the approach to it was through a gateway between two ftone pillars. The houfe was divided into a number of apartments, of which the arrangement did not feem to want either tafte or convenience. This building ftood at the head of the principal village, which confifted of about thirty habitations built of wood, chiefly the bamboo. Behind the village, and on the fide of the hill, was a cave, acceffible only by one way, through an irregular range of rocks. Within the cave, but near its mouth, was a fmall temple, commanding a view of the whole vale. Several other temples were difperfed over the plain, all of which were open in front, with a colonnade before them of round wooden pillars, painted red and varnifhed. The number of houfes on the ifland fcarcely exceeded

ceeded fixty. Behind every houfe, not immediately in the principal village, were inclofures of fugar-canes, tobacco, and other vegetables, growing in great luxuriance. The mountains were covered with verdure, and feemed well calculated for rearing goats, of which the ifland produced a few.

"Befide the principal bay, there were feveral fandy inlets, with fmall patches of level ground behind them. Boats might eafily land in any of thefe inlets; but a communication between them by land appeared to be exceedingly difficult, if not entirely prevented, by the fteep and rugged ridges which feparated them from each other. On this account very flight works, and an eftablifhment of a few men only, would be requifite for the defence of the ifland, a great part of its coaft being impregnably fortified by nature. The depth of water in the bay and road was fufficient for fhips of any burden, and there was perfect fhelter from every wind except the fouth-weft, to which quarter it was directly open. The fhort diftance however, from the continent in that direction would always prevent the fea from rifing high, though it might not be fufficiently near to break the force of the wind."

The inhabitants of this ifland are fo exceedingly fhy and afraid of ftrangers, that upon the approach of the Englifh veffel, they all, except a very few, retired on board their galleys. When the Britifh landed, therefore, they found the doors of all the houfes open, with feveral domeftic animals feeding before them, but neither man, woman, nor child within. After fome time, however, a perfon was perceived lurking among the neighbouring trees, who, finding he was obferved, came forward with reluctance and evident marks of fear. While he was yet at fome diftance, he fell upon his knees, and touched the ground with his forehead feveral times. On approaching to him, it was noticed that the firft joint of every one of his fingers and toes was wanting, and as if twifted off by violence; it was poffible that he might have thus been treated by way of punifhment for fome crime, and that he was confidered as the fitteft perfon to be expofed to the fuppofed danger of watching the movements of the ftrangers coming afhore. In a little time fome others, hidden in the thickets, finding that no mifchief was fuffered by the firft, ventured out. None of them could underftand the Chinefe interpreter; and not being able to read or write, there was no converfing with them by the medium of the Chinefe characters. Recourfe was had to hieroglyphics, and rude figures were drawn of the articles which were propofed to be purchafed; and this method fucceeded tolerably well; poultry and fruits were brought for fale, for which high prices were given, purpofely to conciliate the good will of thofe iflanders. The few that were found grew foon familiar; and one old man preffingly invited the ftrangers to his houfe, fituated upon an eminence, at a little diftance. On arriving there, he introduced them to his wife, an old woman, who, after recovering from her aftonifhment at the fight of figures fo different from thofe fhe had ever been accuftomed to behold, laid, in a neat manner, before them fome fruits, fugar, cakes, and water. On departing from the houfe, this decent and hofpitable couple made figns to teftify their defire of feeing them again."

The poffeffion of this ifland would be of fuch importance to any European nation who wifhed to trade fecurely with TUNG-QUIN and COCHIN-CHINA, that it is faid the French had formerly fome thoughts of purchafing it. Sir George Staunton, however, is of opinion, that the want of fhelter in the fouth-weft monfoon would render it of little value, without a further fettlement near it upon the main land of Cochin-china; and he thinks, that if a folid eftablifhment there could be productive of advantage to any European nation, it would neceffarily be fo to Great Britain; becaufe, befide the opening which it would make for the fale of Britifh manufactures among the people of the country, the Britifh poffeffions in Hindoftan would be fure of a very confiderable demand for their productions.

CALLAO, a fea-port town in the empire of Peru, being the port or harbor of Lima, and is fituated 2 leagues from that city. On the N. fide runs the river which waters Lima, on which fide is a fmall fuburb built only of reeds. There is another on the S. fide; they are both called Pitipifti, and inhabited by Indians. To the E. are extenfive plains, adorned with beautiful orchards watered by canals cut from the river. The town, which is built on a low flat point of land, was ftrongly fortified in the reign of Philip IV.; and numerous batteries command the port and road, which is the greateft, fineft, and fafeft in all the South Sea. There is anchorage every where in very deep water, without danger of rocks or fhoals, except one, which is 3 cables-length from the fhore, about the middle of the ifland of St Lawrence, oppofite La Galatea. The little ifland of Callao lies juft before the town. In the opening between thefe two iflands, there are two fmall iflots, or rather rocks; there is alfo a third very low, but half a league out at fea, S. S. E. from the N. W. point of the ifland of St. Lawrence. Near the fea-fide is the governor's houfe, which, with the viceroy's palace, take up two fides of a fquare; the parifh church makes a third; and a battery of 3 pieces of cannon forms the fourth. The churches are built of canes interwoven, and covered with clay, or painted white. Here are 5 monafteries, and an hofpital. The houfes are in general built of flight materials; the fingular circumftance of its never raining in this country, renders ftone houfes unneceffary; and befides, thefe are more apt to fuffer from earthquakes, which are frequent here. The moft remarkable happened in the year 1746, which laid $\frac{3}{4}$ths of Lima level with the ground, and entirely demolifhed Callao; where the deftruction was fo entire that only one man, of 3000 inhabitants, was left to record this dreadful calamity. S. lat. 12. 1. W. long. 77.—*Morse.*

CALOS, a bay on the W. coaft of the peninfula of E. Florida, where are excellent fifhing banks and grounds. Not far from this is a confiderable town of Seminole Indians. The Spaniards from Cuba take great quantities of fifh here, and barter with the Indians and traders for fkins, furs, &c. and return with their cargoes to Cuba.—*ib.*

CAMBRIDGE, a townfhip in Grafton co. New-Hampfhire, E. of Androfcoggin, and S. of Umbagog Lake.—*ib.*

CAMBRIDGE, a townfhip in Wafhington co. New-York. By the cenfus of 1790, it contained 4996 inhabitants, including 41 flaves. By the ftate cenfus of 1796, it appears there are 623 electors.—*ib.*

CAMBRIDGE, the half fhire town of Middlefex co. Maffachufetts, Maſſachuſetts, is one of the largeſt and moſt reſpectable townſhips of the county. Its 3 pariſhes, Cambridge, Little Cambridge, and Menotomy, contain 3 Congregational meeting houſes, one for Baptiſts, and another for Epiſcopalians; a number of very pleaſant ſeats, and 2115 inhabitants. The elegant bridge which connects this town with Boſton has been deſcribed under the head of Boſton. The compact part of Cambridge is pleaſantly ſituated 3½ miles weſtward of Boſton, on the N. bank of Charles river, over which is a bridge leading to Little Cambridge. It contains about 100 dwelling houſes. Its public buildings, beſides the edifices which belong to Harvard univerſity, are the Epiſcopal and Congregational meeting-houſes, and a handſome court-houſe. The college buildings are 4 in number, and are of brick, named Harvard, Hollis, and Maſſachuſetts Halls, and Holden Chapel. They ſtand on a beautiful green which ſpreads to the N. W. and exhibit a pleaſing view. This univerſity, as to its library, philoſophical apparatus and profeſſorſhips, is at preſent the firſt literary inſtitution on this continent. It takes its date from the year 1638, 7 years after the firſt ſettlement in the townſhip, then called *Newtown*. Since its eſtabliſhment, to July 1794, 3399 ſtudents have received honorary degrees from its ſucceſſive officers. It has generally from 140 to 200 ſtudents. The library contains upwards of 12000 volumes. The cabinet of minerals, in the muſeum, contains the more uſeful productions of nature; and excepting what are called the *precious ſtones*, there are very few ſubſtances yet diſcovered in the mineral kingdom, but what may be found here. The univerſity owes this noble collection of minerals, and ſeveral other natural curioſities, to the munificence of Dr. Lettſom, of London, and to that of the republic of France. N. lat. 42. 23. 28. W. long. from Greenwich 71. 7. 30. —*ib.*

Cambridge, a poſt town of Ninety-Six diſtrict, in the upper country of S. Carolina, where the circuit courts are held. It contains about 60 houſes, a court-houſe and a brick gaol. The college by law inſtituted here is no better than a grammar ſchool. It is 80 miles N. N. W. of Columbia; 50 N by W. of Auguſta, in Georgia, 140 N. W. of Charleſton, and 762 S. W. of Philadelphia. N. lat. 34. 9.—*ib.*

Cambridge, the chief town of Dorcheſter co. Maryland, is ſituated on the S. ſide of Choptank River, about 13 miles E. S. E. from Cook's point at its mouth; 9 W. S. W. from Newmarket, and 57 S. E. from Baltimore. Its ſituation is healthy, and it contains about 50 houſes and a church. N. lat. 38. 34.—*ib.*

Cambridge, in Franklin co. Vermont, is ſituated on both ſides of La Moille River, about 20 miles W. of Lake Champlain and has 359 inhabitants.—*ib.*

CAMDEN *Co.* in Edenton diſtrict, N. Carolina, is in the N. E. corner of the ſtate. It has 4033 inhabitants, including 1038 ſlaves. Joneſborough is the chief town.—*ib.*

Camden, *Diſtrict*, in the upper country of S. Carolina, has Cheraws diſtrict on the N. E. Georgetown diſtrict on the S. E. and the ſtate of N. Carolina on the N.; and is divided into the following counties, Fairfield, Richland, Clarendon, Claremont, Kerſhaw, Salem and Lancaſter. It is 82 miles from N. to S. and 60 from E. to W. and contain 38,265 inhabitants, including 8865 ſlaves. This diſtrict is watered by the Wateree, or Catabaw River and its branches; the upper part is variegated with hills, generally fertile and well watered. It produces Indian corn, wheat, rye, barley, tobacco, and cotton. The Catabaw Indians, the only tribe which reſide in the ſtate, live in the N. part of this diſtrict.—*ib.*

Camden, a poſt town, and chief of Camden diſtrict, S. Carolina, in Kerſhaw co. ſtands on the E. ſide of Wateree River; 35 miles N. E. of Columbia; 55 S. W. of Cheraw; 120 N. by W. of Charleſton, and 643 S. W. of Philadelphia. It is regularly laid out, and contains about 120 houſes, an Epiſcopal church, a court-houſe and gaol. The navigable river on which the town ſtands, enables the inhabitants to carry on a lively trade with the back country. N. lat. 34. 12. W. long. 80. 54.

This town, or near it, was the ſcene of two battles in the late war. On the 16th of Auguſt, 1780, between Gen. Gates and Lord Cornwallis, in which the American general was defeated. The other was a briſk action between Lord Rawdon and Gen. Green, on the 25th of April, 1781. Lord Rawdon ſallied out of the town with 800 men, and attacked the American camp, which was within a mile of the town. The Americans had 126 men killed, and 100 taken priſoners, and the Britiſh had about 100 killed. The town was evacuated the 9th of May, in the ſame year, after Lord Rawdon had burned the gaol, mills, many private houſes, and part of his own baggage.—*ib.*

Camden *Co.* in the lower diſtrict of Georgia, at the S. E. corner of the ſtate, on St Mary's River, contains 305 inhabitants, including 70 ſlaves. Chief town St Patricks.—*ib.*

Camden, a ſmall poſt town on the weſtern ſide of Penobſcot bay, diſtrict of Maine, and the S. eaſternmoſt townſhip of Lincoln co. having Thomaſtown on the S. W.; 35 miles N. N. E. from Pownalborough, and 228 miles N. E. from Boſton.—*ib.*

Camden, a village in Kent co. ſtate of Delaware; about 4 miles S. W. from Dover, and 5 N. weſterly from Frederica.—*ib.*

CAMEL, in navigation, is a machine which has been deſcribed with ſufficient accuracy in the Encyclopædia; but the following account of its invention, given by Profeſſor Beckmann, is perhaps not unworthy of a place in this Supplement.

"In the Zuyder-Zee, oppoſite to the mouth of the river Y, about ſix miles from the city of Amſterdam, there are two ſand banks, between which is a paſſage called the *Pampus*, which is ſufficiently deep for ſmall ſhips, but not for ſuch as are large or heavy laden. In 1672 the Dutch contrived, however, to carry their numerous fleet through this paſſage, by means of large empty cheſts faſtened to the bottom of each ſhip; and this contrivance gave riſe to the invention of the *camel*." In the Encyclopædia its invention is given to the famous De Wit; in the German Cyclopædia to Meyer a Dutch engineer of very conſiderable eminence; but the Dutch writers, almoſt unanimouſly, aſcribe the invention of the camel to a citizen of Amſterdam, who calls himſelf Meeuves Meindertſon Bakker. "Some make the year of the invention to have been 1688, and others 1690. Much has been ſaid of the utility of this invention; but however beneficial it may be, we have reaſon to ſuppoſe that ſuch heavy veſſels as ſhips of war cannot

cannot be raised up, in so violent a manner, without sustaining injury. A sure proof of this is the well known circumstance mentioned by Muschenbroek (*Introductio ad Philosoph. Natur.*), that the ports of a ship which had been raised by the camel could not afterwards be shut closely."

CAMELEON, one of the constellations of the southern hemisphere, near the south pole, and invisible in our latitude. There are 10 stars marked in this constellation in Sharp's catalogue.

CAMELOPARDALUS, a new constellation of the northern hemisphere, formed by Hevelius, consisting of 32 stars, first observed by him. It is situated between Cepheus, Cassiopeia, Perseus, the Two Bears, and Draco; and it contains 58 stars in the British catalogue.

CAMELLIA, in botany (see *Encycl.*), is a plant which the Chinese call *Cha wha*, or flower of tea, on account of the resemblance of the one to the other, and because its petals are sometimes mixed among the teas to increase their fragrance. Sir George Staunton, who calls it *Camellia Sesanqua*, saw it flourishing on the sides and very high tops of mountains, where the soil consisted of little more than fragments of stone, crumbled into a sort of coarse earth by the joint action of the sun and rain. It yields, he says, a nut, from which is expressed an esculent oil, equal to the best which comes from Florence. On this account, it is cultivated in vast abundance; and is particularly valuable from the facility of its culture in situations fit for little else.

CAMPBELL (George, D. D.), so justly admired for his metaphysical acuteness and various erudition, was, in 1719, born at Aberdeen, where his father, the reverend Colin Campbell, was one of the ministers of the established church. He was educated in his native city; and, after passing through the usual course of academical learning, he studied divinity under the Rev. J. Chalmers, professor of divinity in Marischal College.—He was, in 1749, an unsuccessful candidate for the church of Fordown, though his competitor Mr Forbes was a man of very slender abilities, and supposed to be attached to the constitution and liturgy of the church of England. It might indeed be that attachment which contributed principally to procure him the living in preference to Mr Campbell.

The living of Fordown is in the gift of the crown; and it has generally been a rule with his majesty's ministers, to give such livings, when they become vacant, to those candidates who are favoured by the majority of land-owners in the parish. At the era of 1749, the land-owners in some of the northern and middle counties of Scotland were more generally attached to the constitution of the church of England than to that of their own establishment; and such was certainly the case in the parish of Fordown.

But whatever was the cause of Mr Campbell's failure, he failed by a very small number, and was not long without an establishment. In 1750, he was presented, by Sir Thomas Burnett, of Leys, to the living of Banchary Ternan, on the Dee, about twenty miles west from Aberdeen. From this he was translated, or, as the Scotch ecclesiastical phrase is, *transported* to Aberdeen in 1756, and nominated one of the city ministers, in the room of Mr John Bisset deceased, a puritan of the old school, whose strictness and peculiarities are yet remembered by many in that place.

In 1759, on the decease of principal Pollock, he was chosen principal of the Marischal college, and succeeded to the divinity chair in 1771, on Dr Alexander Gerard being translated to the professorship of divinity in King's-college. Before his settling in Aberdeen, he married Miss Grace Farquharson, daughter of Mr Farquharson of Whitehouse, by whom he had no issue. This amiable woman died about a year before him. They were an eminent pattern of conjugal affection.

From this time he enjoyed a remarkable share of good health and spirits. He had, all his life, a rooted aversion to medicine. He got the better of every ailment by a total and rigorous abstinence from all kind of sustenance whatever; and it was not till he was attacked by an alarming illness, about two years before his death, that he was persuaded by his friends to call in medical aid. What nature could do, she had all along performed well; but her day was over, and something of art became necessary. Then, for the first time, he owned the utility of medical men, and declared his recantation of the very mean opinion he had formerly entained of them and their art. A few months before his death, he resigned his offices of principal, professor of divinity, and one of the city ministers, and was in all succeeded by Dr W. L. Brown, late of Utrecht, a man of distinguished abilities. Dr Campbell retained all his faculties entire to the last, and died on the 6th of April 1796, in the 77th year of his age. His character has been so justly drawn by his successor, that we shall give it to our readers in his words, adding only a circumstance or two, which we have reason to think will contribute to endear his memory to every liberal and enlightened mind.

"Dr Campbell, as a public teacher, was long admired for the clearness and copiousness with which he illustrated the great doctrines and precepts of religion, and the strength and energy with which he enforced them. Intimately persuaded of the truth and infinite consequence of what revelation teaches, he was strongly desirous of carrying the same conviction to the minds of his hearers, and delivered his discourses with that zeal which flows from strong impressions, and that power of persuasion which is the result of sincerity of heart, combined with clearness of understanding. He was satisfied, that the more the pure dictates of the gospel were studied, the more they would approve themselves to the mind, and bring forth, in the affections and conduct, all the peaceable fruits of righteousness. The unadulterated dictates of Christianity, he was, therefore, only studious to recommend and inculcate, and knew perfectly to discriminate them from the inventions and traditions of men. His chief study ever was, to direct belief to the great objects of practice; and, without these, he viewed the most orthodox profession as "a sounding brass, and a tinkling cymbal." But, besides the character of a preacher of righteousness, he had also that of a teacher of the science of divinity to sustain. How admirably he discharged this duty, and with what effect he conveyed the soundest and most profitable instruction to the minds of his scholars, let those declare who are now in various congregations of this country, communicating to their fellow

Campbell.

Chriſtians the fruits of their ſtudies under ſo able and judicious a teacher. Diſcarding all attachment to human ſyſtems, merely conſidered as ſuch, he tied his faith to the Word of God alone, poſſeſſed the happieſt talent in inveſtigating its meaning, and communicated to his hearers the reſult of his own inquiries, with a preciſion and perſpicuity which brought light out of obſcurity, and rendered clear and ſimple what appeared intricate and perplexed. He expoſed, without reſerve, the corruptions which ignorance, craft, and hypocriſy, had introduced into religion, and applied his talent for ridicule to the beſt of all purpoſes, to hold up to contempt the abſurdities with which the pureſt and ſublimeſt truths had been loaded.

"Placed at the head of a public ſeminary of learning, he felt all the importance of ſuch a ſituation, and uniformly directed his influence to public utility. His enlarged and enlightened mind, juſtly appreciated the extenſive conſequence of the education of youth. He anticipated all the effects reſulting to the great community of mankind, from numbers of young men iſſuing, in regular ſucceſſion, from the univerſity over which he preſided, and occupying the different departments of ſocial life.

"His benevolent heart delighted to repreſent to itſelf the ſtudents under his direction uſefully and honourably diſcharging the reſpective duties of their diſferent profeſſions; and ſome of them, perhaps, filling the moſt diſtinguiſhed ſtations of civil ſociety. With theſe proſpects before him, he conſtantly directed his public conduct to their attainment. He never ſuffered his judgment to be warped by prejudice or partiality, or his heart to be ſeduced by paſſion or private intereſt. Thoſe mean and ignoble motives by which many are actuated in the diſcharge of important truſts, approached not his mind. A certain honourable pride, if pride it may be called, diffuſed an uniform dignity over the whole of his behaviour. He felt the man degraded by the perverſion of public character. His underſtanding alſo clearly ſhewed him even perſonal advantage attached to ſuch principles and practice, as he adopted from a ſenſe of obligation, and thoſe elevated conceptions of real worth which were ſo congenial to his ſoul. He ſaw, he experienced, eſteem, reſpect, and influence, following in the train of integrity and beneficence; but contempt, diſgrace, averſion, and complete inſignificance, cloſely linked to corruption and ſelfiſhneſs. Little minds are ſeduced and overpowered by ſelfiſh conſiderations, becauſe they have not the capacity to look beyond the preſent advantage, and to extend to the miſery that ſtands on the other ſide of it. The ſame circumſtance that betrays the perverſity of their hearts, alſo evinces the weakneſs of their judgments.

"His reputation as a writer, is as extenſive as the preſent intercourſe of letters; not confined to his own country, but ſpread through every civilized nation. In his literary purſuits, he aimed not, as is very often the caſe, with men of diſtinguiſhed literary abilities, merely at eſtabliſhing his own celebrity, or increaſing his fortune; but had chiefly at heart the defence of the great cauſe of Religion, or the elucidation of her dictates.

"At an early period he entered the liſts as a champion for Chriſtianity againſt one of its acuteſt opponents. He not only triumphantly refuted his arguments, but even conciliated his reſpect by the handſome and dexterous manner in which his defence was conducted. While he refuted the infidel, he ſpared the man, and exhibited the uncommon ſpectacle of a polemical writer poſſeſſing all the moderation of a Chriſtian. But while he defended Chriſtianity againſt its enemies, he was deſirous of contributing his endeavours to increaſe, among its profeſſors, the knowledge of the ſacred writings. Accordingly, in the latter part of his life, he favoured the world with a work, the fruit of copious erudition, of unwearied application, for almoſt thirty years, and of a clear and comprehenſive judgment. We have only to regret, that the other writings of the New Teſtament have not been elucidated by the ſame pen that tranſlated the Goſpels. Nor were his literary merits confined to theology, and the ſtudies more immediately connected with it. Philoſophy, and the fine arts, are alſo indebted to his genius and labours; and in him the polite ſcholar was eminently joined to the deep and liberal divine.

"Political principles will always be much affected by general character. This was alſo the caſe with Dr Campbell. In politics, he maintained that moderation which is the ſureſt criterion of truth and rectitude, and was equally diſtant from thoſe extremes into which men are ſo apt to run on great political queſtions. He cheriſhed that patriotiſm which conſiſts in wiſhing, and endeavouring to promote, the greateſt happineſs of his country, and is always ſubordinate to univerſal benevolence. Firmly attached to the Britiſh conſtitution, he was animated with that genuine love of liberty which it inſpires and invigorates. He was equally averſe to deſpotiſm and to popular anarchy; the two evils into which political parties are ſo frequently hurried, to the deſtruction of all that is valuable in government. Party-ſpirit, of whatever deſcription, he conſidered as having an unhappy tendency to pervert, to the moſt pernicious purpoſes, the beſt principles of the human mind, and to clothe the moſt iniquitous actions with the moſt ſpecious appearances. Although tenacious of thoſe ſentiments, whether in religion or politics, which he was convinced to be rational and juſt, he never ſuffered mere difference of opinion to impair his good will, to obſtruct his good offices, or to cloud the cheerfulneſs of converſation. His own converſation was enlivened by a vein of the moſt agreeable pleaſantry."

So far was he from being influenced by jealouſy, or any portion of that corporation ſpirit which ſometimes incites men of undoubted abilities to detract from the merit of every writer who fills not a ſtation as conſpicuous as their own, that he was loud in his praiſes of thoſe, whom men of meaner minds would have looked upon with diſguſt, as upon preſumptuous rivals. This generoſity was fully experienced by the writer of the article Miracle, in the Encyclopædia, who, though he had preſumed to treat the ſubject differently from Dr Campbell, received from him ſuch a teſtimony of approbation of what he had done, as he will hardly look for from any other man in ſimilar circumſtances.

Among his other qualities, which ſo much endeared him to all who had the honour of his acquaintance, Dr Campbell poſſeſſed an uncommon facility of paſſing from the graveſt to the moſt airy ſubjects, and from the livelieſt to the graveſt, without degrading the one or diminiſhing the pleaſure of the other. The infirmities of age abated not the cheerfulneſs of his temper, nor did even

even the perfuafion of approaching diffolution impair his ferenity.

We cannot conclude this fhort fketch better than with a lift of his works, in the order in which they were publifhed. In 1752, he publifhed a Sermon, preached before the Synod of Aberdeen.

1761. A Differtation on Miracles, againft Mr Hume. This treatife is well known to the learned world. He obtained, and defervedly obtained, a very high reputation, not only from the able manner in which he handled the fubject, but from the liberal ftyle in which he addreffed his antagonift. It was fpeedily tranflated into French, German, and Dutch.

1771. A Sermon before the Society for Propagating Chriftian Knowledge, Edinburgh.

———— before the Synod of Aberdeen.

1776. The Philofophy of Rhetoric, 2 vols 8vo. A work which difcovers a clearnefs of difcernment, and accuracy of obfervation, which juftly intitled him to be ranked among the moft judicious critics. He entered on this inquiry as early as 1750, when a part of the work was compofed. The laws of elegant compofition and criticifm are laid down with great perfpicuity: but the moft valuable part of the work is undoubtedly the *theory of evidence*, to which we know nothing fuperior, perhaps nothing equal, on the fubject, in our own or any other language. His philofophy, in general, is the philofophy of Dr Reid; and where he differs from that acute reafoner refpecting *abftraction*, and fome other objects of metaphyfical difquifition, we think it impoffible to refufe him the pre-eminence in every thing but ftyle.

1777. A Sermon on the King's Faft-day, on Allegiance, firft printed in 4to, and afterwards, at the expence of government, fix thoufand copies were printed in 12mo, enlarged with notes, and fent to America, when the unhappy ftruggle had, however, put on appearances which prevented the effect hoped for from this fermon.

1780. An Addrefs to the People of Scotland on the Alarms which have been raifed by what is called the Popifh Bill. This is a powerful diffuafive from bigotry, and every fpecies of religious perfecution.

1793. His *Magnum Opus*. The tranflation of the Gofpels, with Preliminary Differtations, 2 vols 4to.

CAMPBELL *Co.* in Virginia, lies E. of Bedford co. on Staunton River. It is 45 miles long, and 30 broad, and contains 7,685 inhabitants, including 2,488 flaves.—*Morfe.*

CAMPBELLTOWN, a village in Dauphin co. Pennfylvania, which ftands near a water of Quitipihilla Creek; 13 miles E. of Harrifburgh, and 96 N. W. of Philadelphia.—*ib.*

CAMPBELLTOWN, in N. Carolina, is a large and flourifhing town on a branch of Cape Fear River 100 miles above Wilmington; having, according to Bartram, "above 100 houfes, many wealthy merchants, refpectable public buildings, a vaft refort of inhabitants and travellers, and continual brifk commerce by waggons, from the back fettlements, with large trading boats."—*ib.*

CAMPBELL's *Fort*, in the ftate of Tenneffee, ftands near the junction of Holfton River with the Tenneffee; diftant 135 miles from Abingdon, in Wafhington co. Virginia, and 445 W. of Richmond in Virginia.—*ib.*

CAMPBELL's *Salines*, in North Holfton, in the ftate of Tenneffee, are the only ones that have yet been difcovered on the upper branches of the Tenneffee, though great fearch has been made for them. Large bones, like thofe found at Big Bone Lick, have been dug up here; and other circumftances render the tract which contains the falines a great natural curiofity. Capt. Charles Campbell, one of the firft explorers of the weftern country, made the difcovery of this tract in 1745. In 1753, he obtained a patent for it from the governor of Virginia. His fon the late Gen. William Campbell, the fame who behaved fo gallantly in the years 1780, and 1781, became owner of it on his death. But it was not till the time of his death, when falt was very fcarce and dear, that falt-water was difcovered, and falt made by a poor man. Since that time it has been improved to a confiderable extent, and many thoufands of people are now fupplied from it, with falt of a fuperior quality, and at a low price. The tract confifts of about 300 acres of falt marfh land, of as rich a foil as can be imagined. In this flat, pits are funk, in order to obtain the falt water. The beft is found from 30 to 40 feet deep; after paffing through the rich foil or mud, from 6 to 10 feet, you come to a very brittle lime-ftone rock, with cracks or chafms, through which the falt water iffues into the pits, whence it is drawn by buckets and put into the boilers, which are placed in furnaces adjoining the pits. The hills that furround this flat are covered with fine timber; and a coal mine has been difcovered not far from it. —*ib.*

CAMPEACHY, a town in the audience of Old-Mexico, or New-Spain, and province of Yucatan, fituated on the bay of Campeachy, near the W. fhore. Its houfes are well built of ftone; when taken by the Spaniards it was a large town of 3000 houfes, and had confiderable monuments of Indian art and induftry. There is a good dock and fort, with a governor and garrifon, which commands both the town and harbor. It has been often ftormed and taken, both by the Englifh and French buccaniers, in 1659, 1678, and laft in 1685, when thefe freebooters united, and plundered every place within 15 leagues round it, for the fpace of two months; they afterwards fet fire to the fort and town, which the governor, who kept the field with his men, would not ranfom; and to complete the pillage by a fingular piece of folly, the French buccaniers celebrated the feaft of their king, the day of St Louis, by burning to the value of £.50,000 fterling of Campeachy wood, which was a part of their fhare of the plunder. The port is large but fhallow. It was a ftated market for logwood, of which great quantities grew in the neighbourhood, before the Englifh landed there, and cut it at the ifthmus, which they entered at Triefta Ifland, near the bottom of the bay, 40 leagues S. W. from Campeachy. The chief manufacture here is cotton cloth. Lat. 15. 40. long. 91. 30.—*ib.*

CAMPHOR, or CAMPHIRE (fee *Encycl.*), is, in China, obtained by boiling the branches, twigs, and leaves, of the *Laurus-Camphora* in water, upon the furface of which it is found fwimming in the form of an oil, or adhering, in a glutinous form, to a wooden rod, with which the boiling matter is conftantly ftirred. The glutinous mafs is then mixed with clay and lime, and put into an earthen veffel, with another of the fame fize properly luted over it; the lower veffel being placed over a flow fire, the camphor gradually fublimes through the clay and lime, and adheres to the fides of the upper veffel, forming a cake of a fhape correfponding to the cavity which received it. It is, however, lefs pure and much weaker than what is difcovered in a folid ftate among the fibres of the trunk, as turpentine is found in different forts of pines. In the great, but ill-peopled, ifland of Borneo, and alfo in Japan, the camphor tree is felled for the fole purpofe of finding this coftly drug in fubftance among the fplinters of the trunk, in the fame manner as other trees are felled in Louifiana merely for collecting the fruit they bear upon their fummits. The Borneo, or Japan camphor, is pure, and fo very ftrong, as readily to communicate much of its odour and its virtues to other infpiffated oils, which thus pafs for real camphor; and this adulterated drug is fold by Chinefe artifts at a vaftly lower price than they gave themfelves for the genuine fubftance from Borneo or Japan.

Sir George Staunton, from whom we have this account, does not inform us whether the camphor-tree of China, if felled and torn into fplinters, would not produce as large quantities of the drug, and equally pure, as the trees of Borneo and Japan; but he affures us, that in China it is never fo torn, being there a large and valuable timber-tree. "It is ufed (fays he) in the beft buildings of every kind, as well as for mafts of veffels, and bears too high a price to allow of any part, except the branches, being cut up for the fake of the drug."

CAMPO BELLO, a long and narrow ifland, on the E. coaft of Wafhington co. diftrict of Maine, and the N. eafternmoft of all the iflands of the diftrict. It lies at the mouth of a large bay into which Cobfcook river empties, and has communication with Paffamaquoddy bay on the N. by two channels; the one between the W. fide of Deer Ifland and the continent; the other into the mouth of Paffamaquoddy Bay between Deer Ifland and the N. end of Campo Bello Ifland which lies in about N. lat. 44. 48. The S. end is 5 miles N. wefterly from Grand Mannan Ifland.—*Morse.*

CANABAC, an ifland lying contiguous to Bulam on the weftern coaft of Africa, and inhabited by a fierce people, governed by two kings or chiefs. It would appear that the Canabacs had been very troublefome to their neighbours, fince the inhabitants of fome other iflands in that clufter rejoiced at the fettlement of the Englifh in Bulam, hoping to find in them a defence againft the ufurpations of the Canabacs.

CANADA *Creeks.* There are three creeks which bear this name; one a water of Wood creek, which it meets 4 or 5 miles N. N. W. of Fort Stanwix or New Fort Schuyler. The other two are northern branches of Mohawk River; the *upper* one mingles its waters with the Mohawk in the townfhip of Herkemer, on the German flats, 16 miles below Old Fort Schuyler; over the mouth of it is a fightly and ingenioufly conftructed bridge. The other empties into the Mohawk 13 miles below. Both thefe are long, rapid and unnavigable ftreams, and bring a confiderable acceffion of water to the Mohawk. The lands on thefe creeks are exceedingly rich and valuable, and faft fettling.—*Morse.*

CANADA SAGA, or *Seneca Lake,* a handfome piece of water from 35 to 40 miles long, and about 2 miles broad, in New-York. At the N. W. corner of the Lake ftands the town of Geneva, and on the E. fide between it and Cayuga, are the towns of Romulus, Ovid, Hector and Ulyffes, in Onondago co. New-York. Its outlet is Scayace River which alfo receives the waters of Cayuga Lake 9 miles N. E. from the mouth of Canada Saga, 18 miles below Geneva, on the fame fide of the lake ftands the Friend's fettlement, founded by Jemima Wilkinfon; there are 80 families in it, each has a fine farm, and are quiet, induftrious people.—*ib.*

CANAJOHARY, a poft town in Montgomery co. New-York, fituated on the S. fide of Mohawk River comprehending a very large diftrict of fine country, 40 miles W. of Schenectady, and 56 miles from Albany. In the ftate cenfus of 1796, 730 of the inhabitants appear to be electors. A creek named Canajohary enters the Mohawk in this town. In this townfhip, on the bank of the Mohawk, about 50 miles from Schenectady, is *Indian Caftle,* fo called, the feat of old king Hendrick, who was killed in Sept. 1755, at Lake George, fighting for the Britifh and Americans againft the French. Here are now the remains of a Britifh fort, built during that war, about 60 paces fquare. A gold coin of the value of about 7 dollars was found in thefe ruins in 1793. About a mile and half W. of this fort ftands a church, which is called Brant's church, which the noted chief of that name is faid to have left with great reluctance. This was the principal feat of the Mohawk nation of Indians, and abounds with apple trees of their planting, from which is made cider of an excellent quality.—*ib.*

CANALS of Communication may be of fuch advantage in a commercial or agricultural country, that every attempt to render them more convenient, and lefs expenfive in the conftruction, is intitled to public notice. In the Encyclopædia, an account, fufficiently perfpicuous, is given of the common canals with locks; but in many cafes it is very difficult to provide a fufficient quantity of water for the confumption of a canal where many boats are to pafs. Different attempts have therefore been made, by ingenious men, to fave water in the paffing of boats or lighters from one lock of a canal to another; and, among thefe, perhaps none is more deferving of public favour than the following, by the late Mr James Playfair of Ruffel-ftreet, architect. We fhall ftate his invention in his own words.

"The nature and principle of this manner of faving water confift in letting the water which has ferved to raife or fall a boat or barge from the lock, pafs into refervoirs or cifterns, whofe apertures of communication with the lock are upon different levels, and which may be placed or conftructed at the fide or fides of the lock with which they communicate, or in any other contiguous fituation that circumftances may render eligible; which apertures may be opened or fhut at pleafure, fo that the water may pafs from the lock to each refervoir of the canal, or from each refervoir to the lock, in the following manner: The water which fills the lock, when a boat is to afcend or defcend, inftead of being paffed immediately into the lower part of the canal, is let pafs into thefe cifterns or refervoirs, upon different levels; then, their communications with the lock being fhut, they remain full until another veffel is wanted to pafs; then, again, the cifterns are emptied into the lock, which is thereby nearly filled, fo that only the remainder which is not filled is fupplied from the higher part of the canal. Each of thefe cifterns muft have a furface not lefs than that of the lock, and muft contain half as much water as is meant to be expended for the paffing of each veffel. The ciftern the moft elevated is placed twice its own depth (meafuring by the aperture, or communicating opening of the cifterns) under the level of the water in the higher part of the canal. The fecond ciftern is placed once its own depth under the firft, and fo on are the others, to the loweft; which laft is placed once its own depth above the level of the water in the lower part of the canal. The apertures of the intermediate cifterns, whatever their number may be, muft all be equally divided into different levels; the furface of the water in the one being always on the level of the bottom of the aperture of the ciftern which is immediately above. As an example of the manner and rule for conftructing thefe cifterns, fuppofe that a lock is to be conftructed twelve feet deep, that is, that the veffel may afcend or defcend twelve feet in paffing. Suppofe the lock fixty feet long and fix feet wide, the quantity of water required to fill the lock, and to pafs a boat, is 4320 cubic feet; and fuppofe that, in calculating the quantity of water that can be procured for fupplying the canal, after allowing for wafte, it is found (according to the number of boats that may be expected to pafs) that there will not be above 800 cubic feet for each; then it will be neceffary to fave five-fixths of the whole quantity that in the common cafe would be neceffary: to do which ten cifterns muft be made (the mode of placing which is expreffed in the drawing, fig. 1. Plate VII.), each of which muft be one foot deep, or deeper at pleafure, and each muft have a furface of 360 feet fquare, equal to the furface of the lock. The bottom of the aperture of the loweft ciftern muft be placed one foot above the level of the water in the lower part of the canal, or eleven feet under the level of the high water; the fecond ciftern muft be two feet above the level of the low water; the third three feet, and fo on of the others; the bottom of the tenth, or uppermoft ciftern, being ten feet above the low water, and two feet lower than the high water; and, as each ciftern muft be twelve inches in depth, the furface of the water in the higher ciftern will be one foot under the level of the water in the upper part of the canal. The cifterns being thus conftructed, when the lock is full, and the boat to be let down, the communications between the lock and the cifterns, which until then have all been fhut, are to be opened in the following manner: firft, the communication with the higher ciftern is opened, which, being at bottom two feet under the level of the water in the lock, is filled to the depth of one foot, the water in the lock defcending one foot alfo at the fame time; that communication is then fhut, and the communication between the lock and the fecond ciftern is opened; one foot more of the water then paffes into that ciftern from the lock, and fills it; the opening is then fhut: the fame is done with the third, fourth, fifth, fixth, feventh, eighth, ninth, and tenth, cifterns, one by one, until they are all filled; and, when the tenth, or lowermoft ciftern, is filled, there remains but two feet depth of water in the lock. The communication between the lock and the lower part of the canal is then opened, and the laft two feet depth of water is emptied into the lower part of the canal. By this means, it is evident, that, inftead of twelve feet depth of water being let defcend into the lower part of the canal, there is only two feet depth that defcends, or one-fixth of the whole; therefore, inftead of 4320 cubic feet being ufed, there are only 720 cubic feet ufed: the remainder of the water in the cifterns being ufed as follows. When another boat is to mount, the fluices being then fhut, and the boat in the lock, the tenth or lowermoft ciftern is emptied into the lock, which it fills one foot; the communication being then fhut, the next loweft ciftern, or the ninth, is emptied into the lock, which is thereby filled another foot; and fo, in like manner, all the other cifterns are emptied one after another, until the higher ciftern being emptied, which fills the tenth foot of water in the lock, there remains but two feet of water to fill, which is done from the upper part of the canal, by opening the higher fluice to pafs the boat; by that means, the fame quantity of water defcends from the upper part of the canal into the lock, that in the other cafe defcended from the lock into the lower part of the canal; fo that, in both cafes, the fame quantity of water is faved, that is, five-fixths of what would be neceffary were there no cifterns. Suppofe again that, upon the fame canal, and immediately after the twelve feet lock, it would be advantageous to conftruct one of eighteen feet; then, in order not to ufe any greater quantity of water, it will be neceffary to have fixteen cifterns, upon different levels, communicating with the lock in the fame manner. Should, again, a lock of only fix feet be wanted, after that of eighteen, then it will only be neceffary to have four cifterns on different levels, and fo of any other height of lock. The rule is this: for finding the number and fize of the cifterns, each ciftern being the fame in fuperficies with the lock, its depth muft be fuch as to contain one half the quantity of water meant to be ufed in the paffing of one boat. The depth of the lock, divided by the depth neceffary for fuch a ciftern, will give, in all cafes, the whole number of cifterns, and two more: deduct the number two, therefore, from the number which you find by dividing the depth of the lock by the depth of one ciftern, and you have always the number of cifterns required; which are to be placed upon different levels, according to the rule already given. The above is the principle and manner of ufing the lock, for faving water in canals, and for enabling engineers to conftruct locks of different depths upon the fame canal, without ufing more water for the deep locks than for the fhallow ones. With regard to the manner of difpofing the cifterns, the circumftances of the ground, the declivity, &c. will be the beft guide for the engineer."

But fuppofing a fufficiency of water, or admitting that this method of Mr Playfair's of faving it, where defective, is adequate to his fondeft expectations, ftill, in paffing numerous locks, where the rife is confiderable, the interruption is fo great, that it has often been wifhed that an eligible method of lowering and elevating boats could be devifed, without the affiftance of water-locks. Though this is evidently at firft view practicable, and feveral different modes of doing it have been fuggefted, fome of which have actually been carried into effect, yet all of them have been found to be attended with fuch inconvenience as to render an improvement in this refpect ftill neceffary.

In China, where water-carriage is more generally practiſed than in any kingdom of Europe, boats are raiſed and lowered from one canal into another by ſliding them along an inclined plane: but the contrivances for effecting that purpoſe are ſo awkward, and ſuch a number of hands are required, that it has in general been deemed inexpedient to reſort to that mode of practice in Europe. Several devices that diſcover conſiderable ingenuity, however, have been publiſhed, with a view to facilitate this operation; either by rendering the motion up the inclined plane more equable, or producing a power ſufficient to move theſe great weights. But none of them have yet been ſo ſimple in their conſtruction as could be wiſhed, nor have they afforded ſatisfaction in practice. For the greater part of them, likewiſe, patents have been granted; ſo that whatever be their value, no engineer could avail himſelf of them without previouſly purchaſing a licence from the patentee.

The following contrivance for this purpoſe is the invention of James Anderſon, LL. D. whoſe knowledge of economics is well known, and of whoſe public ſpirit there cannot be a doubt. Inſtead of applying for a patent, to ſecure to himſelf the fruits of his ingenuity, he publiſhed, for the good of his countrymen in general, his device, in the View of the Agriculture of the County of Aberdeen, which he drew up for the conſideration of the board of agriculture. He introduces it to public notice with juſtly obſerving, that it poſſeſſes at leaſt the merit of ſimplicity, in as high a degree, perhaps, as could be wiſhed; and, "in the opinion (ſays he) of very good judges of matters of this ſort, to whom the plan has been ſhewn, it has been deemed fully adequate to the purpoſe of raiſing and lowering boats of a moderate ſize, that is of 20 tons, or downwards; and it is the opinion of moſt men with whom I have converſed, who are beſt acquainted with the inland navigations, that a boat of from 10 to 15 tons is better than thoſe of a larger ſize. When ſeveral are wanted to be ſent at once, they may be affixed to one another, as many as the towing-horſe can conveniently draw. Were boats of this ſize adopted, and were all the boats on one canal to be of the ſame dimenſions, it would prove a great convenience to a country in a ſtate of beginning improvements; becauſe the expence of ſuch a boat would be ſo trifling, that every farmer could have one for himſelf, and might of courſe make uſe of it when he pleaſed, by the aid of his own horſe, without being obliged to have any dependence on the time that might ſuit the convenience of his neighbour; and if two or more boats were going from the ſame neighbourhood, one horſe could ſerve the whole.

"You are to ſuppoſe that fig. 2. (Plate VII.) repreſents a bird's eye view of this ſimple apparatus, as ſeen from above. A is ſuppoſed to be the upper reach of the canal, and B the lower reach, with the apparatus between the two. This conſiſts of three diviſions; the middle one, extending from C to D, is a ſolid piece of maſonry, raiſed from a firm foundation below the level of the bottom of the ſecond reach; this is again divided into five parts, viz. *d d d*, where the wall riſes only to the height of the water in the upper reach, and *e e*, two pillars, raiſed high enough to ſupport the pivots of a wheel or pulley *g*, placed in the poſition there marked.

"The ſecond diviſion *h* conſiſts of a wooden coffer, of the ſame depth nearly as the water in the upper reach, and of a ſize exactly fitted to contain one of the boats. This communicates directly with the upper reach, and being upon the ſame plane with it, and ſo connected with it as to be water-tight, it is evident from inſpection, that nothing can be more eaſy than to float a boat into this coffer from the upper reach; the part of the wheel that projects over it being at a ſufficient height above it, ſo as to occaſion no ſort of interruption.

"Third diviſion. At *i* is repreſented another coffer, preciſely of the ſame dimenſions with the firſt. But here two ſluices, which were open in the former, and only repreſented by dotted lines, are ſuppoſed to be ſhut, ſo as to cut off all communication between the water in the canal and that in the coffer. As it was impoſſible to repreſent this part of the apparatus on ſo ſmall a ſcale, for the ſake of illuſtration it is repreſented more at large in fig. 5. where A, as before, repreſents the upper reach of the canal, and *h* one of the coffers. The ſluice *k* goes into two cheeks of wood, joined to the maſonry of the dam of the canal, ſo as to fit perfectly cloſe; and the ſluice *f* fits, equally cloſe, into cheeks made in the ſide of the coffer for that purpoſe; between theſe two ſluices is a ſmall ſpace *o*. The coffer, and this diviſion *o*, are to be ſuppoſed full of water, and it will be eaſy to ſee that theſe ſluices may be let down, or drawn up at pleaſure, with much facility.

"Fig. 6. repreſents a perpendicular ſection of theſe parts in the ſame direction as in fig. 5. and in which the ſame letters repreſent the ſame parts.

"Things being thus arranged, you are to ſuppoſe the coffer *h* to be ſuſpended, by means of a chain paſſed over the pulley, and balanced by a weight that is ſufficient to counterpoiſe it, ſuſpended at the oppoſite end of the chain. Suppoſe, then, that the counterpoiſe be made ſomewhat lighter than the coffer with its contents, and that the line *m n* (fig. 6.) repreſents a diviſion between the ſolid ſides of the dam of ſeparation, which terminates the upper reach, and the wooden coffer, which had been cloſed only by the preſſure of its own weight (being puſhed a very little from A towards B, beyond its preciſe perpendicular ſwing), and that the joining all round is covered with liſts of cloth put upon it for that purpoſe; it is evident that, ſo long as the coffer is ſuſpended to this height, the joining muſt be water-tight; but no ſooner is it lowered down a little than this joining opens, the water in the ſmall diviſion *o* is allowed to run out, and an entire ſeparation is made between the fixed dam and this moveable coffer, which may be lowered down at pleaſure without loſing any part of the water it contained.

"Suppoſe the coffer now perfectly detached, turn to fig. 3. which repreſents a perpendicular ſection of this apparatus, in the direction of the dotted line *p p* (fig. 2.). In fig. 3. *h* repreſents an end view of the coffer, indicated by the ſame letter as in fig. 2. ſuſpended by its chain, and now perfectly detached from all other objects, and balanced by a counterpoiſe *i*, which is another coffer exactly of the ſame ſize, as low down as the level of the lower reach. From inſpection only it is evident, that, in proportion as the one of theſe weights riſes, the other muſt deſcend. For the preſent, then, ſuppoſe that the coffer *h* is by ſome means rendered

Canals.

rendered more weighty than *i*, it is plain it will defcend while the other rifes; and they will thus continue till *h* comes down to the level of the lower reach, and *i* rifes to the level of the higher one.

"Fig. 4. reprefents a fection in the direction A B (fig. 2.), in which the coffer *i* (feen in both fituations) is fuppofed to have been gradually raifed from the level of the lower reach B, to that of the higher A, where it now remains ftationary; while the coffer *h* (which is concealed behind the mafonry) has defcended in the mean time to the level of the lower reach, where it clofes by means of the juncture *r s*, fig. 6. (which juncture is covered with lifts of cloth, as before explained at *m n*, and is of courfe become water-tight,) when, by lifting the fluice *t*, and the correfponding fluice at the end of the canal, a perfect communication by water is eftablifhed between them. If, then, inftead of water only, this coffer had contained a boat, floated into it from the upper reach, and then lowered down, it is very plain, that when thefe fluices were removed, after it had reached the level of the lower reach, that boat might have been floated out of the coffer with as much facility as it was let into it above. Here then we have a boat taken from the higher into the lower canal; and, by reverfing this movement, it is very obvious that it might be, with equal eafe, raifed from the lower into the higher one. It now only remains that I fhould explain by what means the equilibrium between thefe counter-balancing weights can be deftroyed at pleafure, and the motion of courfe produced.

"It is very evident, that if the two correfponding coffers be precifely of the fame dimenfions, their weight will be exactly the fame when they are both filled to the fame depth of water. It is equally plain, that fhould a boat be floated into either or both of them, whatever its dimenfions or weight may be, fo that it can be contained afloat in the coffer, the weight of the coffer and its contents will continue precifely the fame as when it was filled with water only: hence, then, fuppofing one boat is to be lowered, or one to be raifed at a time, or fuppofing one to be raifed and another lowered at the fame time—they remain perfectly in equilibrium in either place, till it is your pleafure to deftroy that equilibrium. Suppofe then, for the prefent, that both coffers are loaded with a boat in each, the double fluices both above and below clofed; and fuppofe alfo that a ftop-cock *u*, in the under edge of the fide of the lower coffer (fig. 4. and 6.), is opened, fome of the water which ferved to float the boat in the coffer will flow out of it, and confequently that coffer will become lighter than the higher one; the upper coffer will of courfe defcend, while the other mounts upwards. When a gentle motion has been thus communicated, it may be prevented from accelerating, merely by turning the ftop cock fo as to prevent the lofs of more water, and thus one coffer will continue to afcend, and the other to defcend, till they have affumed their ftations refpectively; when, in confequence of a ftop below, and another above, they are rendered ftationary at the level of the refpective canals (A).

"Precifely the fame effect will be produced when the coffers are filled entirely with water.

"It is unneceffary to add more to this explanation, except to obferve, that the fpace for the coffer to defcend into muft be deeper than the bottom of the lower canal, in order to allow a free defcent for the coffer to the requifite depth; and of courfe it will be neceffary to have a fmall conduit to allow the water to get out of it. Two or three inches free, below the bottom of the canal, is all that would be neceffary.

"Where the height is inconfiderable, there will be no occafion for providing any counterpoife for the chain, as that will give only a fmall addition to the weight of the undermoft coffer, fo as to make it preponderate, in circumftances where the two coffers would otherwife be in perfect equilibrium: but, where the height is confiderable, there will be a neceffity for providing fuch a counterpoife; as, without it, the chain by becoming more weighty every foot it defcended, would tend to deftroy the equilibrium too much, and accelerate the motion to an inconvenient degree. To guard againft this inconvenience, let a chain of the fame weight, per foot, be appended at the bottom of each coffer, of fuch a length as to reach within a few yards of the ground where the coffer is at its greateft height (fee fig. 3.); it will act with its whole weight upon the higheft coffer while in this pofition; but, as that gradually defcended, the chain would reach the ground, and, being there fupported, its weight would be diminifhed in proportion to its defcent; while the weight of the chain on the oppofite fide would be augmented in the fame proportion, fo as to counterpoife each other exactly, in every fituation, until the uppermoft chain was raifed from the ground. After which it would increafe its weight no more; and, of courfe, would then give the under coffer that preponderance which is neceffary for preferving the machine fteady. The under coffer, when it reached its loweft pofition, would touch the bottom on its edges, which would then fupport it, and keep every thing in the fame pofition, till it was made lighter for the purpofe of afcending.

"What conftitutes one particular excellence of the apparatus here propofed is, that it is not only unlimited as to the extent of the rife or depreffion of which it is fufceptible (for it would not require the expenditure of one drop more water to lower it one hundred feet than one foot); but it would alfo be eafy fo to augment the number of pulleys at any one place as to admit of two, three, four, or any greater number of boats being lowered or elevated at the fame time; fo that let the fucceffion of boats on fuch a canal be nearly as rapid as that of carriages upon a highway, none of them need be delayed one moment to wait an opportunity of paffing; a thing that is totally impracticable where water-locks are employed; for the intercourfe, on every canal conftructed with water-locks, is neceffarily limited to a certain degree, beyond which it is impoffible to force it.

"For example; fuppofe a hundred boats are following each other, in fuch a rapid fucceffion as to be only half

(A) "It does not feem neceffary to adopt any other contrivance than the above for regulating the motions; but if it fhould be found neceffary, it would be eafy to put a ratch-wheel on the fame axle.

half a minute behind each other: By the apparatus here propofed, they would all be elevated precifely as they came; in the other, let it be fuppofed that the lock is fo well conftructed as that it takes no more than five minutes to clofe and open it; that is, ten minutes in the whole to each boat (for the lock, being once filled, muft be again emptied before it can receive another in the fame direction): at this rate, fix boats only could be paffed in an hour, and of courfe it would take fixteen hours and forty minutes to pafs the whole hundred; and as the laft boat would reach the lock in the fpace of fifty minutes after the firft, it would be detained fifteen hours and fifty minutes before its turn would come to be raifed. This is an immenfe detention; but if a fucceffion of boats, at the fame rate, were to follow continually, they never could pafs at all. In fhort, in a canal conftructed with water-locks, not more than fix boats, on an average, can be paffed in an hour, fo that beyond that extent all commerce muft be ftopped; but, of the plan here propofed, fixty, or fix hundred, might be paffed in an hour if neceffary, fo as to occafion no fort of interruption whatever. Thefe are advantages of a very important nature, and ought not to be overlooked in a commercial country.

"This apparatus might be employed for innumerable other ufes as a moving power, which it would be foreign to our prefent purpofe here to fpecify. Nor does its power admit of any limitation, but that of the ftrength of the chain, and of the coffers which are to fupport the weights. All the other parts admit of being made fo immoveably firm as to be capable of fupporting almoft any affignable weight.

"I will not enlarge on the benefits that may be derived from this very fimple apparatus: its cheapnefs, when compared with any other mode of raifing and lowering veffels that has ever yet been practifed, is very obvious; the wafte of water it would occafion is next to nothing; and when it is confidered that a boat might be raifed or lowered fifty feet nearly with the fame eafe as five, it is evident that the interruptions which arife from frequent locks would be avoided, and an immenfe faving be made in the original expence of the canal, and in the annual repairs.

"It is alfo evident, that an apparatus, on the fame principle might be eafily applied for raifing coals or metals from a great depth in mines, wherever a very fmall ftream of water could be commanded, and where the mine was level-free."

CANANDAQUA, a poft town, lake, and creek, in Ontario co. New-York. It is the fhire town of the co. fituated on the N. end of the lake of the fame name, at its outlet into Canandaqua creek. The lake is about 20 miles long and 3 broad, and fends its waters in a N. eaftward and eaftward courfe 35 miles to Seneca River. This is the fcite of an ancient Indian town of the fame name, and ftands on the road from Albany to Niagara, 22 miles E. from Hartford in Geneffee River; 16 miles W. of Geneva, and 235 miles N. W. from New-York city, meafuring in a ftraight line, and 340 by Albany road. This fettlement was begun by Meffrs. Gorham and Phelps, and is now in a flourifhing ftate. There are about 30 or 40 houfes, fituated on a pleafant flope from the lake; and the adjoining farms are under good cultivation. By the ftate cenfus of 1796, it appears there are 291 electors in this townfhip.—*Morse.*

CANARY-BIRD, of which a defcription is given in the Encyclopædia, was not known in Europe till towards the end of the 15th century. Even in 1555, Bellon, who about that time defcribed all the birds then known, does not fo much as mention it. When it was firft brought from the Canary Iflands, it was fo dear that it could be purchafed only by people of fortune, who were often impofed upon. It was called the *fugar-bird*, becaufe it was faid to be fond of the fugar-cane, and could eat fugar in great abundance. This is rather a fingular circumftance, fugar being to many fowls a poifon. Experiments have fhewn, that a pigeon, to which four drams of fugar was given, died in four hours; and that a duck, which had fwallowed five drams, did not live feven hours.

In the middle of the laft century canary-birds began to be bred in Europe; and to this the following circumftance, related by Olina, feems to have given occafion: "A veffel which, among other commodities, was carrying a number of canary birds to Leghorn, was wrecked on the coaft of Italy; and thefe birds being thus fet at liberty, flew to the neareft land, which was the ifland of Elba, where they found the climate fo favourable, that they multiplied, and perhaps would have become domefticated, had they not been caught in fnares; for it appears that the breed of them there has been long deftroyed. Olina fays, that the breed foon degenerated; but it is probable, that by much the greater part of thefe canary-birds were males, which coupling with birds of the ifland, produced mules, fuch as are defcribed by Gefner and other naturalifts."

"Various treatifes have been publifhed in different languages on the manner of breeding thefe birds, and many people have made it a trade, by which they have acquired confiderable gain. It does no difcredit to the induftry of the Tyrolians, that they have carried it to the greateft extent. At Ymft there is a company, who, after the breeding feafon is over, fend out perfons to different parts of Germany and Switzerland to purchafe birds from thofe who breed them. Each perfon brings with him commonly from three to four hundred, which are afterwards carried for fale, not only through every part of Germany, but alfo to England, Ruffia, and even Conftantinople. About fixteen hundred are brought every year to England; where the dealers in them, notwithftanding the confiderable expence they are at, and after carrying them about on their backs, perhaps a hundred miles, fell them for five fhillings a piece. This trade, hitherto neglected, is now carried on in Schwarzwalde; and at prefent there is a citizen at Gottingen who takes with him every year to England feveral canary-birds and bulfinches *(loxia pyrrhula)*, with the produce of which he purchafes fuch fmall wares as he has occafion for."—*Profeffor Beckmann's Hiftory of Inventions and Difcoveries.*

Canary-Seed. See Phalaris, *Encycl.*—Profeffor Beckmann doubts whether the plant which bears the canary-feed be the *phalaris* of the ancients, becaufe that name feems to have been given by Pliny to more than one fpecies of grafs. He thinks it very probable, however, that the plant which the modern botanifts call *phalaris* was firft brought from the Canary Iflands to Spain, Candle.

Spain, where it began to be cultivated, as well as in the fouth of France, as foon as canary-birds came into general efteem. At prefent it is cultivated in various places, and forms no inconfiderable branch of trade, particularly in the ifland of Sicily, where it is called *Scagliuola* or *Scaghiola*. Were it not that the grains are not eafily freed from the hufks, this plant might be cultivated for the food of man, for its feeds yield a good kind of meal. The phalaris has by feveral writers been confounded with *argol* or the *lichen rocolla* of Linnæus; but they are very different plants. See LICHEN *Rocolla* in this Supplement.

CANDLE, a thing fo univerfally known as to need no particular defcription. Its ufe, however, is fo great, that every information tending to its improvement muft, we fhould think, be acceptable to our readers. Of the common method of making candles, whether of wax or of tallow, a fufficient account has been given in the Encyclopædia; but candles of every kind are far from being yet brought to that degree of perfection of which they feem fufceptible. Thus, for example, the light of a candle, which is fo exceedingly brilliant when firft fnuffed, is very fpeedily diminifhed to one-half, and is ufually not more than one-fifth or one-fixth, before the uneafinefs of the eye induces us to fnuff it. Hence it follows, that if candles could be made fo as not to require fnuffing, the average quantity of light afforded by the fame quantity of combuftible matter would be more than doubled. It may likewife be worthy of inquiry, fince the coft and duration of candles are eafily afcertainable, whether more or lefs light is obtained at the fame expence during a given time, by burning a number of fmall candles inftead of one of greater thicknefs.

To determine this laft point, a method muft be found of meafuring the comparative intenfities of light, for which fee PHOTOMETER in this Supplement. With refpect to the defideratum firft mentioned, we have fome very ingenious obfervations and well-contrived experiments by Mr Nicholfon, in the fecond number of his valuable Journal, which we fhall here infert nearly in the words of their author.

In every procefs of combuftion the free accefs of air is of the utmoft confequence. When a candle has a very flender wick, the flame is fmall and of a brilliant white colour; if the wick be large, the combuftion is lefs perfect, and the flame brown; and a wick ftill larger, not only exhibits a brown flame, but the lower internal part appears dark, and is occupied by a portion of volatilized matter, which does not become ignited till it has afcended towards the point. When the wick is either very large or very long, part of this matter efcapes combuftion, and fhews itfelf in the form of coal or fmoke. The fame things take place in the burning of a lamp; but when the wick of a lamp is once adjufted as to its length, the flame continues nearly in the fame ftate for a much longer time than the flame of a candle.

"Upon comparing a candle with a lamp (fays Mr Nicholfon), two very remarkable particulars are immediately feen. In the firft place, the tallow itfelf, which remains in the unfufed ftate, affords a cup or cavity to hold that portion of melted tallow which is ready to flow into the lighted part of the wick. In the fecond place, the combuftion, inftead of being confined, as in the lamp, to a certain determinate portion of the fibrous matter, is carried, by a flow fucceffion, through the whole length. Hence arifes the greater neceffity for frequent fnuffing the candle; and hence alfo the ftation of the freezing point of the fat oil becomes of great confequence. For it has been fhewn, that the brilliancy of the flame depends very much on the diameter of the wick being as fmall as poffible; and this requifite will be moft attainable in candles formed of a material that requires a higher degree of heat to fufe it. The wick of a tallow candle muft be made thicker in proportion to the greater fufibility of the material, which would otherwife melt the fides of the cup, and run over in ftreams. The flame will therefore be yellow, fmoky, and obfcure, excepting for a fhort time immediately after fnuffing. Tallow melts at the 92d degree of Fahrenheit's thermometer; fpermaceti at the 133d degree; the fatty matter formed of flefh, after long immerfion in water, melts at 127 degrees; the *pela* of the Chinefe at 145 degrees; bees-wax at 142 degrees; and bleached wax at 155 degrees. Two of thefe materials are well known in the fabrication of candles. Wax in particular does not afford fo brilliant a flame as tallow; but, on account of its lefs fufibility, the wick can be made fmaller, which not only affords the advantage of a clear perfect flame, but from its flexibility it is difpofed to turn on one fide, and come in contact with the external air, which completely burns the extremity of the wick to white afhes, and thus performs the office of fnuffing. We fee therefore that the important object to fociety of rendering tallow candles equal to thofe of wax, does not at all depend on the combuftibility of the refpective materials, but upon a mechanical advantage in the cup, which is afforded by the inferior degree of fufibility in the wax; and that, to obtain this valuable object, one of the following effects muft be produced: Either the tallow muft be burned in a lamp, to avoid the gradual progreffion of the flame along the wick; or fome means muft be devifed to enable the candle to fnuff itfelf, as the wax candle does; or, laftly, the tallow itfelf muft be rendered lefs fufible by fome chemical procefs. I have no great reafon to boaft of fuccefs in the endeavour to effect thefe; but my hope is, that the facts and obfervations here reprefented may confiderably abridge the labour of others in the fame purfuit.

"The makers of thermometers and other fmall articles with the blow-pipe and lamp, give the preference to tallow inftead of oil, becaufe its combuftion is more complete, and does not blacken the glafs. In this operation the heat of the lamp melts the tallow which is occafionally brought into its vicinity by the workman. But for the ufual purpofes of illumination, it cannot be fuppofed that a perfon can attend to fupply the combuftible matter. Confiderable difficulties arife in the project for affording this gradual fupply as it may be wanted. A cylindrical piece of tallow was inferted into a metallic tube, the upper aperture of which was partly clofed by a ring, and the central part occupied by a metallic piece nearly refembling that part of the common lamp which carries the wick. In this apparatus the piece laft defcribed was intended to anfwer the fame purpofe, and was provided with a fhort wick. The cylinder of tallow was fupported beneath in fuch a manner that the metallic tube and other part of this lamp

Candle. lamp were left to reſt with their whole weight upon the tallow at the ring or contraction of the upper aperture. In this ſituation the lamp was lighted. It burned for ſome time with a very bright clear flame, which, when compared with that of a candle, poſſeſſed the advantage of uniform intenſity, and was much ſuperior to the ordinary flame of a lamp in its colour, and the perfect abſence of ſmell. After ſome minutes it began to decay, and very ſoon afterwards went out. Upon examination, it was found that the metallic piece which carried the wick had fuſed a ſufficient quantity of tallow for the ſupply during the combuſtion; that part of this tallow had flowed beneath the ring, and to other remote parts of the apparatus, beyond the influence of the flame; in conſequence of which, the tube and the cylinder of tallow were faſtened together, and the expected progreſſion of ſupply prevented. It ſeems probable, that in every lamp for burning conſiſtent oils, the material ought to be ſo diſpoſed that it may deſcend to the flame upon the principle of the fountain reſervoir. I ſhall not here ſtate the obſtacles which preſent themſelves in the proſpect of this conſtruction, but ſhall diſmiſs the ſubject by remarking, that a contrivance of this nature would be of the greateſt public utility.

"The wick of a candle being ſurrounded by the flame, is nearly in the ſituation of a body expoſed to deſtructive diſtillation in a cloſe veſſel. After loſing its volatile products, the carbonaceous reſidue retains its figure, until, by the deſcent of the flame, the external air can have acceſs to its upper extremity. But, in this caſe, the requiſite combuſtion, which might ſnuff it, is not effected: for the portion of oil emitted by the long wick is not only too large to be perfectly burned, but alſo carries off much of the heat of the flame while it aſſumes the elaſtic ſtate. By this diminiſhed combuſtion and increaſed efflux of half-decompoſed oil, a portion of coal or ſoot is depoſited on the upper part of the wick, which gradually accumulates, and at length aſſumes the appearance of a fungus. The candle does not then give more than one-tenth of the light emitted in its beſt ſtate. Hence it is that a candle of tallow cannot ſpontaneouſly ſnuff itſelf. It was not probable that the addition of a ſubſtance containing vital air or oxygene would ſupply that principle at the preciſe period of time required; but as experiment is the teſt of every probability of this nature, I ſoaked a wick of cotton in a ſolution of nitre, then dried it, and made a candle. When this came to be lighted, nothing remarkable happened for a ſhort time; at the expiration of which a decrepitation followed at the lower extremity of the flame, which completely divided the wick where the blackened part commences. The whole of the matter in combuſtion therefore fell off, and the candle was of courſe inſtantly extinguiſhed. Whether this would have happened in all proportions of the ſalt or conſtructions of the candle I did not try, becauſe the ſmell of azote was ſufficiently ſtrong and unpleaſant to forbid the uſe of nitre in the purſuit. From various conſiderations I am diſpoſed to think that the ſpontaneous ſnuffing of candles made of tallow, or other fuſible materials, will ſcarcely be effected but by the diſcovery of ſome material for the wick which ſhall be voluminous enough to abſorb the tallow, and at the ſame time ſufficiently flexible to bend on one ſide.

"The moſt promiſing ſpeculation reſpecting this moſt uſeful article, ſeems to direct itſelf to the cup which Candle. contains the melted tallow. The imperfection of this part has already been noticed, namely, that it breaks down by fuſion, and ſuffers its fluid contents to eſcape. The Chineſe have a kind of candle about half an inch in diameter, which, in the harbour of Canton, is called a *lobchock*; but whether the name be Chineſe, or the corruption of ſome European word, I am ignorant. The wick is of cotton, wrapped round a ſmall ſtick or match of the bamboo cane. The body of the candle is white tallow; but the external part, to the thickneſs of perhaps one-thirtieth of an inch, conſiſts of a waxy matter coloured red. This covering gives a conſiderable degree of ſolidity to the candle, and prevents its guttering, becauſe leſs fuſible than the tallow itſelf. I did not obſerve that the ſtick in the middle was either advantageous or the contrary; and as I now write from the recollection of this object at ſo remote a period as 25 years ago, I can only conjecture that it might be of advantage in throwing up a leſs quantity of oil into the flame than would have been conveyed by a wick of cotton ſufficiently ſtout to have occupied its place unſupported in the axis of the candle.

"Many years ago I made a candle in imitation of the lobchock. The expedient to which I had recourſe conſiſted in adapting the wick in the uſual pewter mould: wax was then poured in, and immediately afterwards poured out: the film of wax which adhered to the inner ſurface of the mould ſoon became cool, and the candle was completed by filling the mould with tallow. When it was drawn out it was found to be cracked longitudinally on its ſurface, which I attributed to the contraction of the wax, by cooling, being greater than that of the tallow. At preſent I think it equally probable that the cracking might have been occaſioned by too ſudden cooling of the wax before the tallow was poured in; but other avocations prevented the experiments from being varied and repeated. It is probable that the Chineſe external coating may not be formed of pure hard bleached wax.

"But the moſt deciſive remedy for the imperfection of this cheapeſt, and in other reſpects beſt material, for candles, would undoubtedly be to diminiſh its fuſibility. Various ſubſtances may be combined with tallow, either in the direct or indirect method. In the latter way, by the decompoſition of ſoap, a number of experiments were made by Berthollet, of which an account is inſerted in the Memoirs of the Academy at Paris for the year 1780, and copied into the 26th volume of the *Journal de Phyſique.* None of theſe point directly to the preſent object; beſides which, it is probable that the ſoap made uſe of by that eminent chemiſt was formed not of tallow, but oil. I am not aware of any regular ſeries of experiments concerning the mutual action of fat oils and other chemical agents, more eſpecially ſuch as may be directed to this important object of diminiſhing its ſolubility; for which reaſon I ſhall mention a few experiments made with this view.

1. Tallow was melted in a ſmall ſilver veſſel. Solid tallow ſinks in the fluid, and diſſolves without any remarkable appearance. 2. Gum ſandarach in tears was not diſſolved, but emitted bubbles, ſwelled up, became brown, emitted fumes, and became criſp or friable. No ſolution nor improvement of the tallow. 3. Shell-lac ſwelled up with bubbles, and was more perfectly fuſed than

than the gum fandarach in the former experiment. When the tallow was poured off, it was thought to congeal rather more fpeedily. The lac did not appear to be altered. 4. Benzoin bubbled without much fwelling, was fufed, and emitted fumes of an agreeable fmell, though not refembling the flowers of benzoin. A flight or partial folution feemed to take place. The benzoin was fofter and of a darker colour than before, and the tallow lefs confiftent. 5. Common refin unites very readily with melted tallow, and forms a more fufible compound than the tallow itfelf. 6. Camphor melts eafily in tallow, without altering its appearance. When the tallow is near boiling, camphoric fumes fly off. The compound appeared more fufible than tallow. 7. The acid or flowers of benzoin diffolves in great quantities without any ebullition or commotion. Much fmoke arifes from the compound, which does not fmell like the acid of benzoin. Tallow alone does not fume at a low heat, though it emits a fmell fomething like that of oil olive. When the proportion of the acid was confiderable, fmall needled cryftals appeared as the temperature diminifhed. The appearances of feparation are different according to the quantity of acid. The compound has the hardnefs and confiftence of firm foap, and is partially tranfparent. 8. Vitriolated tartar, nitre, white fugar, cream of tartar, cryftallized borax, and the falt fold in the markets under the name of falt of lemons, but which is fuppofed to be the effential falt of forrel, or vegetable alkali fuperfaturated with acid of fugar, were refpectively tried without any obvious mutual action or change of properties in the tallow. 9. Calcined magnefia rendered tallow opaque and turbid, but did not feem to diffolve. Its effect refembled that of lime.

" It is propofed to try the oxygenated acetous acid, or radical vinegar; the acid of ants, of fugar, of borax, of galls, the tanning principle, the ferous and gelatinous animal matter, the fecula of vegetables, vegetable gluten, bird-lime, and other principles, either by direct or indirect application. The object, in a commercial point of view, is entitled to an extenfive and affiduous inveftigation. Chemifts in general fuppofe the hardnefs or lefs fufibility of wax to arife from oxygen; and to this object it may perhaps be advantageous to direct a certain portion of the inquiry. The metallic falts and calces are the combinations from which this principle is moft commonly obtained; but the combinations of thefe with fat oils have hitherto afforded little promife of the improvement here fought. The fubject is, however, fo little known, that experiments of the loofeft and moft conjectural kind are by no means to be defpifed."

Thus far Mr Nicholfon: but it is probable that many of the advantages which he propofes by thefe mixtures might be obtained merely by purifying the tallow, and keeping it in that ftate for a long time expofed to the air before it be formed into candles. It is certain that tallow is rendered more difficult of fufion by age; and this is the fole reafon that old candles are lefs apt to run, and therefore more valuable than fuch as have been lately made.

CANIADERAGO, a lake in Otfego co. New-York, nearly as large as Otfego lake, and 6 miles W. of it. A ftream called Oaks Creek iffues from it, and falls into Sufquehanna River about 5 miles below Otfego. The beft cheefe in the ftate is faid to be made on this creek.—*Morse.*

CANNARES, Indians of the province of Quito, in Peru. They are very well made, and very active; they wear their hair long, which they weave and bind about their heads, in form of a crown. Their clothes are made of wool or cotton, and they wear fine fafhioned boots. Their women are handfome, and fond of the Spaniards; they generally till and manure the ground, whilft their hufbands at home, card, fpin, and weave wool and cotton. Their country had many rich gold mines, now drained by the Spaniards. The land bears good wheat and barley, and has fine vineyards. The magnificent palace of *Theomabamba* was in the country of the Cannares.—*ib.*

CANNAVERAL, CAPE, the extreme point of rocks on the E. fide of the peninfula of E. Florida. It has Mofquitos Inlet N. by W. and a large fhoal S. by E. This was the bounds of Carolina by charter from Charles II. N. lat. 28. 35. W. long. 81. 9.—*ib.*

CANONGOES, in Bengal, are the regifters of land and hereditary expounders of the ufages of the country. They have their officers and deputies everywhere; they are not liable to removal; and all papers attefted by them are received as authentic and decifive, in all difputes relative to lands and their boundaries. See *Sir Charles Roufe Boughton's Differtation on the Landed Property of Bengal.*

CANONNICUT *Ifland*, in Newport co. Rhode-Ifland, lies about 3 miles W. of Newport, the S. end of which, (called Beaver Tail, on which ftands the light-houfe) extends about as far S. as the S. end of Rhode Ifland. It extends N. about 7 miles, its average breadth being about one mile; the E. fhore forming the W. part of Newport-harbor, and the W. fhore being about 3 miles from the Narraganfet fhore. On this point is Jameftown. It was purchafed of the Indians in 1657, and in 1678, was incorporated by the name of Jameftown. The foil is luxuriant, producing grain and grafs in abundance.—Jameftown contains 507 inhabitants, including 16 flaves.—*Morse.*

CANONSBURG, a town in Wafhington co. Pennfylvania, on the N. fide of the W. branch of Chartiers Creek, which runs N. by E. into Ohio River about 5 miles below Pittfburg. In its environs are feveral valuable mills. Here are about 50 houfes and an academy; 7 miles N. E. by E. of Wafhington, and 15 S. W. of Pittfburg.—*ib.*

CANTERBURY, a townfhip in Rockingham co. New-Hampfhire, fituated on the eaftern bank of Merrimack River; 14 miles N. by W. of Concord, 45 N. W. of Exeter, and 48 from Portfmouth. It contains 1038 inhabitants.—*ib.*

Canterbury, a townfhip in Windham co. Connecticut, on the W. fide of Quinnabaug River which feparates it from Plainfield. It is 7 miles E. by S. of Windham, and about 10 or 12 N. of Norwich.—*ib.*

CANTON, a new townfhip in Norfolk co. Maffachufetts, incorporated in 1797, it being formerly the northerly part of Stoughton.—*ib.*

CAOUTCHOUC, Elastic Gum, or *Indian Rubber*, is a fubftance of which a pretty full account has been given in the Encyclopædia. It has there been likewife obferved how ufeful it might be, if we could form

Caoutchouc.

form it into catheters and other flexible instruments, by dissolving it in a menstruum less expensive, or at least more easily attained, than ether. Since that article was published, we have seen an account of such a menstruum in the *Annales de Chimie*, by M. Grossart (Chirly); and of the expence of that menstruum, or the difficulty of procuring it, no complaint will be made, when it is known to be nothing more than very hot water.

The author was led to this discovery by some experiments made with ether on caoutchouc; of which he gives the following account:

"It appeared, even in my first experiments, that I was attempting too much, and giving myself useless trouble, in searching for a manner of completely dissolving the elastic gum, so that it might be again made up in new forms. I then thought that it would be easier to find out a method, as it were, of soldering it, and of not acting upon it more than might be necessary to cause its softened parts to reunite. Experience has shewn me, that a strong pressure made upon two pieces of caoutchouc (when brought to that state of softness,) and continued until they are entirely dry, caused them to contract so strong an adhesion, that the piece, being pulled out till it broke, often broke, not at the united part, but by the side of it.

"By means of ether I immediately succeeded in making these tubes. The method which appears to me to succeed the best is, to cut a bottle circularly in a spiral slip of a few lines in breadth. It is very easy to cut a bottle in such a manner as to form a single long slip, and thus unnecessary joinings are avoided.

"The whole slip is to be plunged into ether, until it is sufficiently softened, which comes to pass sooner or later according to the quality of the vitriolic ether that is employed. Half an hour frequently suffices; but I have already observed, that there is a great diversity in the manner in which different sorts of vitriolic ether act, and of which the cause is not yet, so far as I know, determined.

"The slip being taken out, one of the extremities is to be taken hold of and rolled, first upon itself at the bottom of the tube, pressing it; then the rolling is to be continued, mounting spirally along the mould, and taking care to lay over and compress with the hand every edge, one against the other, so that there may not be any vacant space, and that all the edges may join exactly. The whole then is to be bound hard with a tape of an inch in width, taking care to turn it the same way with the slip of elastic gum. The tape is to be tied up with packthread, so that, by every turn of the packthread joining another, an equal pressure is given to every part: it is then left to dry, and the tube is made.

"The bandage is to be taken off with great care, that none of the outward surfaces, which may have been lodged within the hollows of the tape (of which the caoutchouc takes the exact impression), may be pulled away. I advise the application of a tape before packthread, because, especially in the thinner tubes, we should run the risk of cutting the caoutchouc, if the packthread were applied immediately upon it.

"It is easy to take off the tube of elastic gum which has been formed upon a solid mould of one piece; if the mould be made rather conic, it may be made to slide off by the smaller end; at the worst, it is easily accomplished by plunging it into hot water; for it is softened by the heat, and is distended; without this precaution it would be sometimes difficult to draw it off when dry, because, having been applied upon the mould whilst it had its volume augmented by the interposition of the ether, the parts of the caoutchouc are drawn nearer each other, by the evaporation of the interposed bodies.

"The great affinity between these two bodies is seen by the length of time that the odour of the ether remains, notwithstanding the great volatility of the latter, and that the apparent dryness of the tube seems to shew that there is none remaining; nevertheless, after a certain time, the odour disappears entirely. One of those tubes, which was made with ether after the method here described, does not retain the least trace of the solvent. It is needless to say, that it is easy to make tubes as thin or as thick as may be judged proper.

"Although the process that I am now describing is but very little expensive, yet I have tried to employ other solvents in lieu of ether, because it is not to be had in every place, and requires particular care in its preservation. I have employed, with some success, the essential oils of lavender and of turpentine: both of them speedily dilate the caoutchouc, and are of no great price. The disagreeable smell of the oil of turpentine becomes, perhaps, in process of time, less disagreeable than that of lavender. This last is dearer; but the difference is not so great as it appears at first: for we may make some advantage of the oil of lavender that is employed by the following operation: Upon plunging into alcohol the elastic tube prepared with the oil of lavender, the alcohol charges itself with the oil, and forms a very good lavender-water; the same as would be made by an immediate mixture of oil of lavender with spirit of wine. Immersion in this liquor also serves to hasten the drying of the caoutchouc instruments thus made by means of essential oils. I have made tubes with the oils of turpentine and of lavender; both are much slower in evaporating than ether. The oil of turpentine particularly appeared to me always to have a kind of stickiness, and I know not as yet that we have any means whereby to get speedily rid of its smell.

"Nevertheless there is a solvent which has not that inconvenience; it is cheaper, and may easily be procured by every one: this solvent is *water*. I conceive it will appear strange to mention water as a solvent of elastic gum, that liquid having been always supposed to have no action upon it. I myself resisted the idea; but reflecting that ether, by being saturated with water, is the better enabled to act on caoutchouc, and that this gum when plunged into boiling water becomes more transparent at the edges, I presumed that this effect was not due simply to the dilation of its volume by the heat. I thought that, at that temperature, some action might take place, and that a long-continued ebullition might produce more sensible effects. I was not disappointed in my expectations, and one of those tubes was prepared without any other solvent than water and heat. I proceeded in the same manner as with ether: the elastic gum dilates but very little in boiling water; it becomes whitish, but recovers its colour again by drying it in the air and light. It is sufficiently prepared for use when it has been a quarter of an hour in boiling water:

water: by this time its edges are sometimes transparent. It is to be turned spirally round the mould, in the manner we described before, and replunged frequently into the boiling water, during the time that is employed in forming the tube, to the end that the edges may be disposed to unite together. When the whole is bound with packthread, it is to be kept some hours in boiling water; after which it is to be dried, still keeping on the binding.

"If we wish to be more certain that the connection is perfect, the spiral may be doubled; but we must always avoid placing the exterior surfaces of the slips one upon the other, as these surfaces are the parts which most resist the action of solvents. This precaution is less necessary when ether is employed, on account of its great action upon the caoutchouc.

"It might be feared that the action of water upon caoutchouc would deprive us of the advantages which might otherwise be expected; but these fears will be removed, if we consider that the affinities differ according to the temperatures; that it is only at a very high temperature that water exercises any sensible action upon caoutchouc. I can affirm, that at 120° of Reaumur's thermometer (302° of Fahrenheit) this affinity is not such as that the water can give a liquid form to caoutchouc; and it does not appear that we have any thing to fear in practice from a combination between these two bodies, which, though it really is a true solution, does not take place in any sensible degree but at a high temperature. It is therefore at present easy to make of caoutchouc whatever instruments it may be advantageous to have of a flexible, supple, and elastic substance, which is impermeable to water at the temperature of our atmosphere, and resists the action of acids as well as that of most other solvents. As to the durability of these instruments, few substances promise more than this, because it may be soldered afresh in a damaged part. Any woven substance may be covered with it; it is only required that the substance should be of a nature not to be acted upon during the preparation, either by ether or by boiling water; for these two agents are those which appear to me to merit the preference. Artists will frequently find an advantage in employing ether, as it requires less time; so that a person may make, in a single day, any tube he may have occasion for. The expence of ether is very little, since it is needful only to dispose the caoutchouc to adhere; and being brought into that state, the caoutchouc may be kept in a vessel perfectly well closed. It would also diminish the expence of the ether if, instead of washing it with a large quantity of water, there should be added to it only as much water as it can take up."

CAP and BUTTON, are two small islands, or rather rocks, lying in longitude 105° 48′ 30″ east; and in latitude, the former 5° 58′ 30″: the latter 5° 49′ south. They were visited by some of the persons attending Lord Macartney on his embassy to China; and are thus described by Sir George Staunton.

"At a little distance they might be mistaken for the remains of old castles, mouldering into heaps of ruins, with tall trees already growing upon the tops; but at a nearer view, they betrayed evident marks of a volcanic origin. Explosions from subterraneous fires, produce, for the most part, hills of a regular shape, and terminating in truncated cones; but when from a subaqueous volcano eruptions are thrown up above the surface of the sea, the materials, falling back into the water, are more irregularly dispersed, and generally leave the sides of the new creation naked and misshapen, as in the instance of AMSTERDAM, and of those smaller spots called, from some resemblance in shape, the Cap and Button.

"In the Cap were found two caverns, running horizontally into the side of the rock; and in these were a number of those birds nests so much prized by the Chinese epicures. They seemed to be composed of fine filaments cemented together by a transparent viscous matter, not unlike what is left by the foam of the sea upon stones alternately covered by the tide, or those gelatinous animal substances found floating on every coast. The nests adhere to each other, and to the sides of the cavern, mostly in rows, without any break or interruption. The birds that build these nests are small grey swallows, with bellies of a dirty white. They were flying about in considerable numbers: but they were so small, and their flight so quick, that they escaped the shot fired at them. The same nests are said also to be found in deep caverns, at the foot of the highest mountains in the middle of Java, and at a distance from the sea, from which the birds, it is thought, derive no materials, either for their food or the construction of their nests; as it does not appear probable they should fly, in search of either, over the intermediate mountains, which are very high, or against the boisterous winds prevailing thereabouts. They feed on insects, which they find hovering over stagnated pools between the mountains, and for catching which their wide opening beaks are particularly adapted. They prepare their nests from the best remnants of their food. Their greatest enemy is the kite, who often intercepts them in their passage to and from the caverns, which are generally surrounded with rocks of grey limestone or white marble. The nests are placed in horizontal rows at different depths, from 50 to 500 feet. The colour and value of the nests depend on the quantity and quality of the insects caught, and perhaps also on the situation where they are built. Their value is chiefly determined by the uniform fineness and delicacy of their texture; those that are white and transparent being most esteemed, and fetching often in China their weight in silver. These nests are a considerable object of traffic among the Javanese, and many are employed in it from their infancy. The birds having spent near two months in preparing their nests, lay each two eggs, which are hatched in about fifteen days. When the young birds become fledged, it is thought time to seize upon their nests, which is done regularly thrice a year, and is effected by means of ladders of bamboo and reeds, by which the people descend into the cavern; but when it is very deep, rope ladders are preferred. This operation is attended with much danger; and several break their necks in the attempt. The inhabitants of the mountains generally employed in it begin always by sacrificing a buffalo; which custom is constantly observed by the Javanese on the eve of every extraordinary enterprise. They also pronounce some prayers, anoint themselves with sweet-scented oil, and smoke the entrance of the cavern with gum-benjamin. Near some of those caverns a tutelar goddess is worshipped, whose priest burns incense, and lays his protecting hands on every person preparing to descend into the cavern. A flambeau is carefully prepared at the same time, with a gum which exudes from a tree growing in the vicinity, and is not easily extinguished by fixed air or subterraneous vapours. The swallow, which builds those nests, is described as not having its tail feathers marked with white spots, which is a character attributed to it by Linnæus; and it is possible that there are two species or varieties of the swallow, whose nests are alike valuable." See *Birds-Nests*, Encycl.

CAPE of Good Hope. See *Good Hope*, both in *Encycl.* and this *Supplement*.

CAPE ST. ANDREWS, on the coast of Paraguay, or La Plata, S. America. S. lat. 38. 50. W. long. 59. 46.—*Morse.*

Cape St. Antonio, or *Anthonio*, is the point of land on the southern side of La Plata River in S. America, which, with Cape St Mary on the northward, forms the mouth of that river. S. lat. 36. 32. W. long. 56. 34.—*ib.*

Cape St. Augustine, on the coast of Brazil, S. America, lies southward of Pernambuco. S. lat. 10. 15. W. long. 35. 13.—*ib.*

Cape Blow-me-down, which is the southern side of the entrance from the bay of Fundy into the Basin of Minas, is the easternmost termination of a range of mountains, extending about 80 or 90 miles to the gut of Annapolis; bounded N. by the shores of the bay of Fundy, and S. by the shores of Annapolis river.—*ib.*

Cape Cod, anciently called *Mallebarre*, by the French, is the S. eastward point of the bay of Massachusetts, opposite Cape Ann. N. lat. 42. 4. W. long. from Greenwich, 70. 14.—*ib.*

Cape Elizabeth, a head-land and township in Cumberland co. district of Maine. The cape lies in N. lat. 43. 33. E. by S. from the centre of the town 9 miles; about 20 S. westerly of Cape Small Point, and 12 N. E. from the mouth of Saco River. The town has Portland on the N. E. and Scarborough S. W. and contains 1355 inhabitants. It was incorporated in 1765, and lies 126 miles N. E. of Boston.—*ib.*

Cape Fear, is the southern point of Smith's Island which forms the mouth of Cape Fear River into two channels, on the coast of N. Carolina; S. W. of Cape Look-Out, and remarkable for a dangerous shoal called the Frying Pan, from its form. Near this cape is Johnson's Fort, in Brunswick co. and district of Wilmington. N. lat. 33. 32. W. long. 78. 25.

Cape Fear *River* more properly Clarendon, affords the best navigation in N. Carolina. It opens to the Atlantic ocean by two channels. The S. western and largest channel between the S. W. end of Smith's Island at Bald Head, where the light-house stands, and the E. end of Oakes Island, S. W. from Fort Johnston. The new inlet is between the sea-coast and the N. E. end of Smith's Island. It will admit vessels drawing 10 or 11 feet, and is about 3 miles wide at its entrance, having 18 feet water at full tides over the bar. It continues its breadth to the flats, and is navigable for large vessels 21 miles from its mouth, and 14 from Wilmington; to which town vessels drawing 10 or 12 feet can reach without any risk. As you ascend this river you leave Brunswick on the left, and Wilmington on the right. A little above Wilmington, the river divides into N. E. and N. W. branches. The former is broader than the latter, but is neither so deep nor so long. The N. W. branch rises within a few miles of the Virginia line, and is formed by the junction of Haw and Deep rivers. Its general course is S. easterly. Sea vessels can go 25 miles above Wilmington, and large boats 90 miles, to Fayetteville. The N. E. branch joins the N. W. branch a little above Wilmington, and is navigable by sea vessels 20 miles above that town, and by large boats to South Washington, 40 miles further, and by rafts to Sarecto, which is nearly 70 miles. The whole length of Cape Fear river is about 200 miles.—*ib.*

Cape May, is the S. westernmost point of the state of New-Jersey, and of the county to which it gives name. N. lat. 39. W. long. 75. 2. It lies 20 miles N. E. from Cape Henlopen, which forms the S. W. point of the mouth of Delaware bay, as Cape May does the N. E.—*ib.*

Cape May *Co.* spreads northward, around the cape of its name, is a healthy, sandy tract of country, of sufficient fertility to give support to 2571 industrious and peaceable inhabitants. The county is divided into Upper, Middle, and Lower precincts.—*ib.*

CAPITAL of a Bastion, is an imaginary line dividing any work into two equal and similar parts; or a line drawn from the angle of the polygon to the point of the bastion, or from the point of the bastion to the middle of the gorge.

CAPRA, or the She-goat, a name given to the star Capella, on the left shoulder of Auriga, and sometimes to the constellation Capricorn. Some again represent Capra as a constellation in the northern hemisphere, consisting of three stars, comprised between the 45th and 55th degree of latitude.—The poets fable her to be Amalthea's goat, which suckled Jupiter in his infancy.

CAPUT Draconis, or *Dragon's Head*, a name given by some to a fixed star of the first magnitude, in the head of the constellation Draco.

CARACCAS, a province of Terra Firma, S. America, lying on the southern coast of the Caribbean Sea. This coast is bordered in its greatest length by a chain of mountains, running E. and W. and divided into many fruitful vallies, whose direction and opening are towards the N. It has maritime fortified towns, Puerto Cabelo, and La Guayra. The Dutch carry thither to the Spaniards all sorts of European goods, especially linen, making vast returns of silver and cocoa. The cocoa tree grows here in abundance. There are from 500 to 2000 trees in a walk, or plantation. These nuts are passed for money, and are used as such in the bay of Campeachy. N. lat. 10. 12. W. long. 67. 10.—*Morse.*

CARANGAS, a province and jurisdiction under the bishop of Plata, and 70 leagues W. of that city, in Peru, very barren in corn and grain, &c. but abounding in cattle. Here are a great number of silver mines constantly worked, among which that called Tureo, and by the miners Machacado, is very remarkable. The fibres of the silver forming an admirable intermixture with the stone; such mines are generally the richest. There are other masses of silver in this province equally remarkable, being found in the barren sandy desarts, where they find, by digging only, detached

lumps

Carbon ‖ Carlisle.

lumps of silver, unmixed with any ore or stone. These lumps are called *papas*, because taken out of the ground as that root is, and have the appearance of melted silver; which proves that they are thus formed by fusion. Some of these papas have weighed from 50 to 150 marks, being a Paris foot in length.—*ib.*

CARBON. See CHEMISTRY in this *Supplement*, Part I. Chap. II. Sect. iii.

CARLISLE, the chief town of Cumberland co. Pennsylvania, on the post road from Philadelphia to Pittsburgh; is 125 miles W. by N. from the former, and 178 E. from the latter, and 18 S. W. from Harrisburgh. Its situation is pleasant and healthy, on a plain near the southern bank of Conedogwinet creek, a water of the Susquehanna. The town contains about 400 houses, chiefly of stone and brick, and about 1500 inhabitants. The streets intersect each other at right angles, and the public buildings are a college, court-house and gaol, and 4 edifices for public worship. Of these the Presbyterians, Germans, Episcopalians, and Roman Catholics, have each one. Dickinson College, named after the celebrated John Dickinson, Esq. author of several valuable tracts, has a principal, 3 professors, a philosophical apparatus, and a library containing near 3000 volumes. Its revenue arises from £.4000 in funded certificates, and 10,000 acres of land. In 1787 there were 80 students, and its reputation is daily increasing. About 40 years ago this spot was inhabited by Indians, and wild beasts.—*Morse.*

Carlisle ‖ Carp.

CARLISLE, a bay on the W. side of the island of Barbadoes, in the West-Indies, situated between James and Charles Forts, on which stands Bridgetown, the capital of the island, in N. lat. 13. 9. W. long. 60. 3. —*ib.*

CARMEL, a township in Dutchess co. New-York. By the state census of 1796, 237 of its inhabitants were electors.—*ib.*

CAROLINE *Co.* in Virginia, is on the S. side of Rappahannock River, which separates it from King George's co. It is about 40 miles square, and contains 17,489 inhabitants, including 10,292 slaves.—*ib.*

CAROLINE *Co.* on the eastern shore in Maryland, borders on Delaware state to the E. and contains 9506 inhabitants, including 2057 slaves. Its chief town Danton —*ib.*

CARP. See CYPRINUS, both in the *Encycl.* and in this *Supplement.*

CARPENTRY,

1 Definition.

THE art of framing timber for the purposes of architecture, machinery, and, in general, for all considerable structures.

It is not intended in this article to give a full account of carpentry as a *mechanical* art, or to describe the various ways of executing its different works, suited to the variety of materials employed, the processes which must be followed for fashioning and framing them for our purposes, and the tools which must be used, and the manner in which they must be handled: This would be an occupation for volumes; and though of great importance, must be entirely omitted here. Our only aim at present will be to deduce, from the principles and laws of mechanics, and the knowledge which experience and judicious inferences from it have given us concerning the strength of timber, in relation to the strain laid on it, such maxims of construction as will unite economy with strength and efficacy.

This object is to be attained by a knowledge, 1st, of the strength of our materials, and of the absolute strain that is to be laid on them; 2dly, of the modifications of this strain, by the place and direction in which it is exerted, and the changes that can be made by a proper disposition of the parts of our structure; and, 3dly, having disposed every piece in such a manner as to derive the utmost advantage from its relative strength, we must know how to form the joints and other connections in such a manner as to secure the advantages derived from this disposition.

2 An important branch of mechanical science.

This is, evidently, a branch of mechanical science, which makes carpentry a *liberal* art, constitutes part of the learning of the ENGINEER, and distinguishes him from the workman. Its importance in all times and states of civil society is manifest and great. In the present condition of these kingdoms, raised, by the active ingenuity and energy of our countrymen, to a pitch of prosperity and influence unequalled in the history of the world, a condition which consists chiefly in the superiority of our manufactures, attained by prodigious multiplication of engines of every description, and for every species of labour, the SCIENCE (so to term it) of carpentry is of immense consequence. We regret therefore exceedingly, that none of our celebrated artists have done honour to themselves and their country, by digesting into a body of consecutive doctrines the results of their great experience, so as to form a system from which their pupils might derive the first principles of their education. The many volumes called COMPLETE INSTRUCTORS, MANUALS, JEWELS, &c. take a much humbler flight, and content themselves with instructing the mere workman, or sometimes give the master builder a few approved forms of roofs and other framings, with the rules for drawing them on paper; and from thence forming the working draughts which must guide the saw and the chissel of the workman. Hardly any of them offer any thing that can be called a principle, applicable to many particular cases, with the rules for this adaptation. We are indebted for the greatest part of our knowledge of this subject to the labours of literary men, chiefly foreigners, who have published in the memoirs of the learned academies dissertations on different parts of what may be termed the *science of carpentry*. It is singular, that the members of the Royal Society of London, and even of that established and supported by the patriotism of these days for the encouragement of the arts, have contributed so little to the public instruction in this respect. We observe of late some beginnings of this kind, such as the last part of Nicholson's CARPENTERS AND JOINERS ASSISTANT, published by J. Taylor, Holburn, 1797. And it

3 Principally indebted to foreigners for a knowledge of this subject.

it is with pleasure that we can say, that we were told by the editor, that this work was prompted in a great measure by what has been delivered in the *Encyclopædia* in the articles ROOF and *STRENGTH of Materials*. It abounds more in important and new observations than any book of the kind that we are acquainted with. We again call on such as have given a scientific attention to this subject, and pray that they would render a meritorious service to their country by imparting the result of their researches. The very limited nature of this work does not allow us to treat the subject in detail; and we must confine our observations to the fundamental and leading propositions.

4 Theory, founded on what.

The theory (so to term it) of carpentry is founded on two distinct portions of mechanical science, namely, a knowledge of the strains to which framings of timber are exposed, and a knowledge of their *relative* strength.

We shall therefore attempt to bring into one point of view the propositions of mechanical science that are more immediately applicable to the art of carpentry, and are to be found in various articles of our work, particularly ROOF and *STRENGTH of Materials*. From these propositions we hope to deduce such principles as shall enable an attentive reader to comprehend distinctly what is to be aimed at in framing timber, and how to attain this object with certainty: and we shall illustrate and confirm our principles by examples of pieces of carpentry which are acknowledged to be excellent in their kind.

5 Composition and resolution of forces

The most important proposition of general mechanics to the carpenter is that which exhibits the composition and resolution of forces; and we beg our practical readers to endeavour to form very distinct conceptions of it, and to make it very familiar to their mind. When accommodated to their chief purposes, it may be thus expressed:

Plate VIII.

1. If a body, or any part of a body, be at once pressed in the two directions AB, AC (fig. 1.), and if the intensity or force of those pressures be in the proportion of these two lines, the body is affected in the same manner as if it were pressed by a single force acting in the direction AD, which is the diagonal of the parallelogram ABDC formed by the two lines, and whose intensity has the same proportion to the intensity of each of the other two that AD has to AB or AC.

Such of our readers as have *studied* the laws of motion, know that this is fully demonstrated. We refer them to the article MECHANICS, n° 5, &c. where it is treated at some length. Such as wish for a very accurate view of this proposition, will do well to read the demonstration given by D. Bernoulli, in the first volume of the *Comment. Petropol.* and the improvement of this demonstration by D'Alembert in his *Opuscles*, and in the *Comment. Taurinens.* The practitioner in carpentry will get more useful confidence in the doctrine, if he will shut his book, and verify the theoretical demonstrations by actual experiments. They are remarkably easy and convincing. Therefore it is our request that the artist, who is not so habitually acquainted with the subject, do not proceed further till he has made it quite familiar to his thoughts. Nothing is so conducive to this as the actual experiment; and since this only requires the trifling expence of two small pulleys and a few yards of whipcord, we hope that none of our practical readers will omit it: They will thank us for this injunction.

6 Illustrated by experiment.

2. Let the threads A*d*, AF*b*, and AE*c* (fig. 2), have the weights *d*, *b*, and *c*, appended to them, and let two of the threads be laid over the pulleys F and E. By this apparatus the knot A will be drawn in the directions AB, AC, and AK. If the sum of the weights *b* and *c* be greater than the single weight *d*, the assemblage will of itself settle in a certain determined form; if you pull the knot A out of its place, it will always return to it again, and will rest in no other position. For example, if the three weights are equal, the threads will always make equal angles, of 120 degrees each, round the knot. If one of the weights be three pounds, another four, and the third five, the angle opposite to the thread stretched by five pounds will always be square, &c. When the knot A is thus in equilibrio, we must infer, that the action of the weight *d*, in the direction A*d*, is in direct opposition to the combined action of *b*, in the direction AB, and of *c*, in the direction AC. Therefore, if we produce *d*A to any point D, and take AD to represent the magnitude of the force, or pressure exerted by the weight *d*, the pressures exerted on A by the weights *b* and *c*, in the directions AB, AC, are in fact equivalent to a pressure acting in the direction AD, whose intensity we have represented by AD. If we now measure off by a scale on AF and AE the lines AB and AC, having the same proportions to AD that the weights *b* and *c* have to the weight *d*, and if we draw DB and DC, we shall find DC to be equal and parallel to AB, and DB equal and parallel to AC; so that AD is the diagonal of a parallelogram ABDC. We shall find this always to be the case, whatever are the weights made use of; only we must take care that the weight which we cause to act without the intervention of a pulley be less than the sum of the other two: if any one of the weights exceeds the sum of the other two, it will prevail, and drag them along with it.

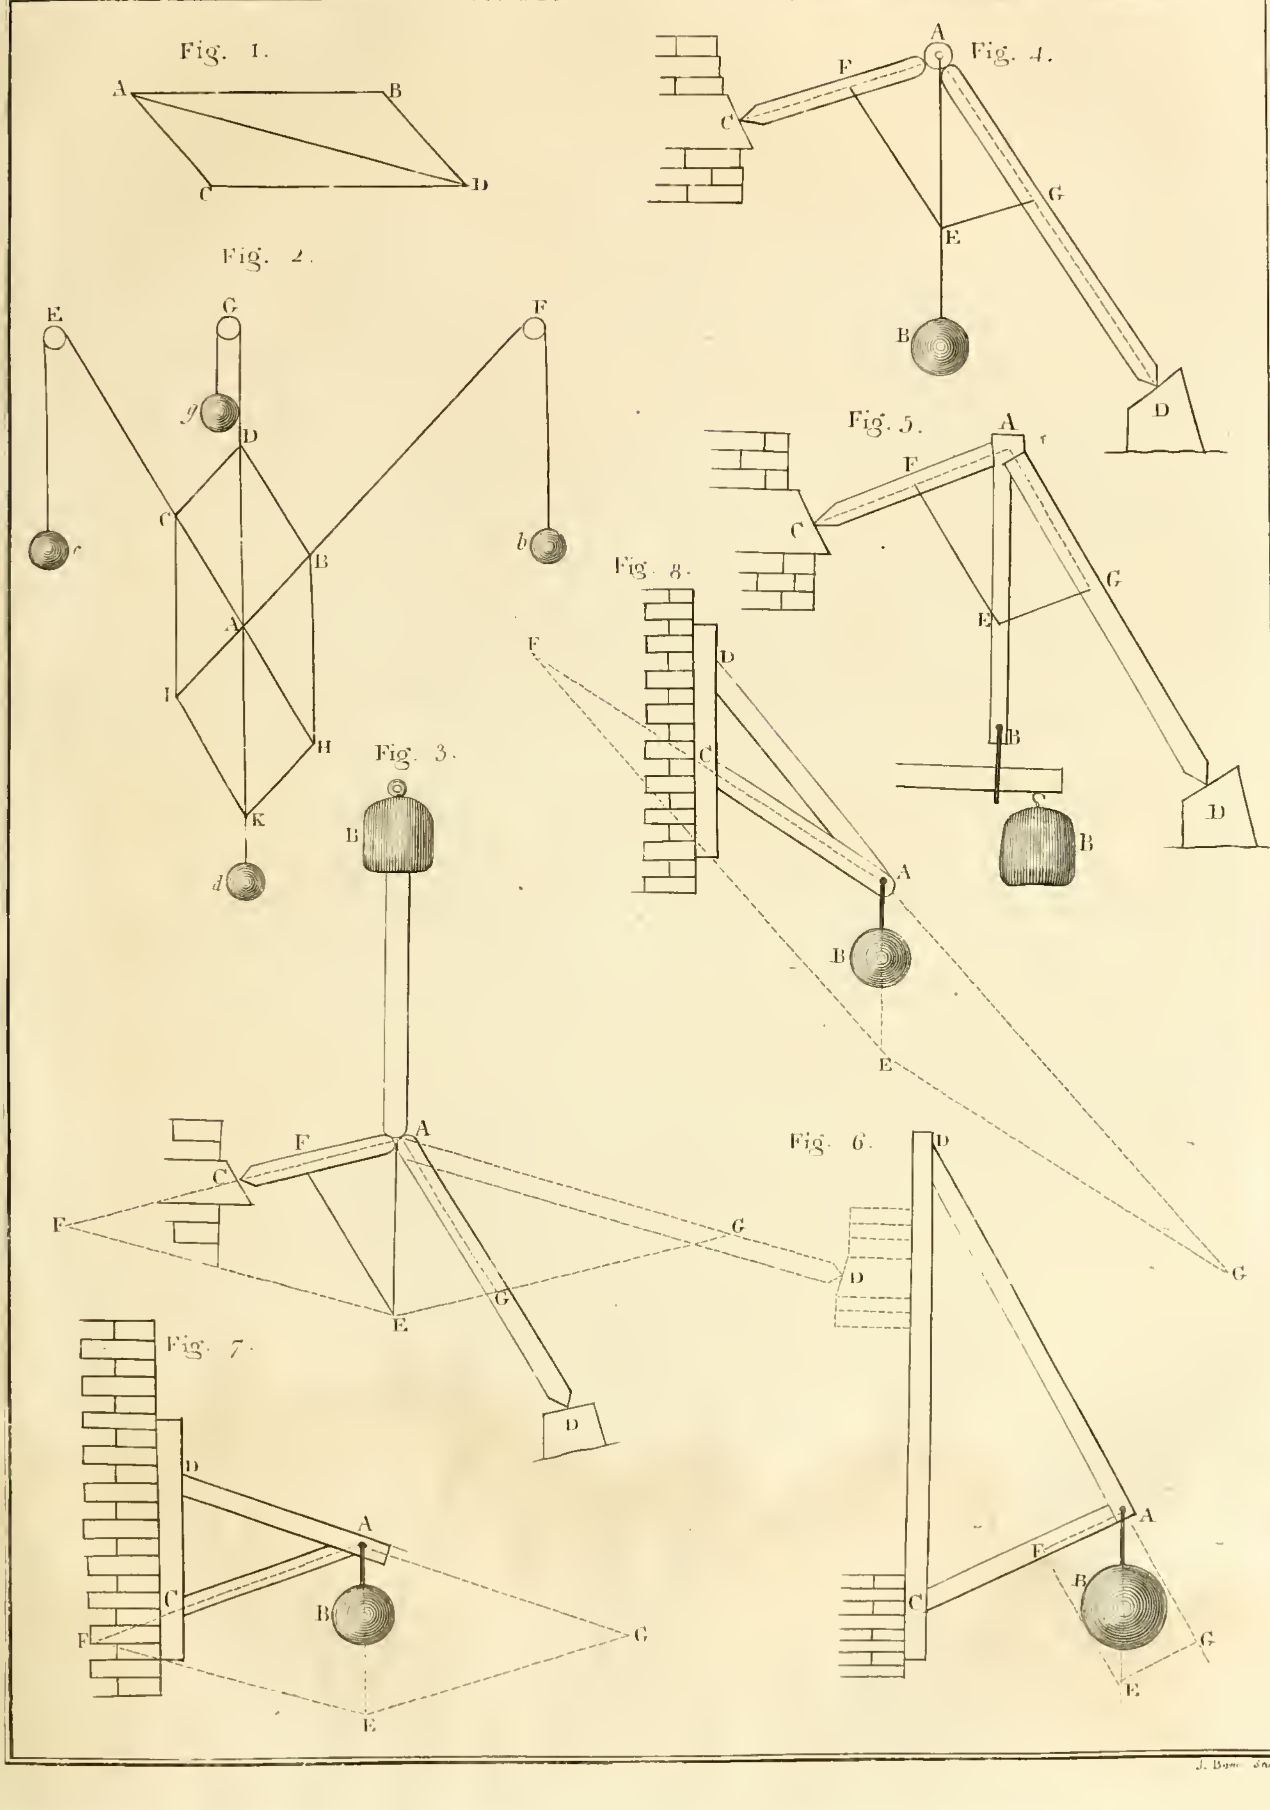
Now since we know that the weight *d* would just balance an equal weight *g* pulling directly upwards by the intervention of the pulley G; and since we see that it just balances the weights *b* and *c* acting in the directions AB, AC, we must infer, that the knot A is affected in the same manner by those two weights, or by the single weight *g*; and therefore, that *two pressures, acting in the directions, and with the intensities,* AB, AC, *are equivalent to a single pressure having the direction and proportion of* AD. In like manner, the pressures AB, AK, are equivalent to AH, which is equal and opposite to AC. Also AK and AC are equivalent to AI, which is equal and opposite to AB.

We shall consider this combination of pressures a little more particularly. 7 Considered more particularly.

Suppose an upright beam BA (fig. 3.) pushed in the direction of its length by a load B, and abutting on the ends of two beams, AC, AD, which are firmly resisted at their extreme points C and D, which rest on two blocks, but are nowise joined to them: these two beams can resist no way but in the directions CA, DA; and therefore the pressures which they sustain from the beam BA are in the directions AC, AD. We wish to know how much each sustains? Produce BA to E, taking AE from a scale of equal parts, to represent the number of tons or pounds by which BA is pressed.

Draw

CARPENTRY PLATE VIII.



Draw EF and EG parallel to AD and AC; then AF, measured on the same scale, will give us the number of pounds by which AC is strained or crushed, and AG will give the strain on AD.

It deserves particular remark here, that the length of AC or AD has no influence on the strain, arising from the thrust of BA, while the directions remain the same. The effects, however, of this strain are modified by the length of the piece on which it is exerted. This strain compresses the beam, and will therefore compress a beam of double length twice as much. This may change the form of the assemblage. If AC, for example, be very much shorter than AD, it will be much less compressed: The line CA will turn about the centre C, while DA will hardly change its position; and the angle CAD will grow more open, the point A sinking down. The artist will find it of great consequence to pay a very minute attention to this circumstance, and to be able to see clearly the change of shape which necessarily results from these mutual strains. He will see in this the cause of failure in many very great works.—By thus changing shape, strains are often produced in places where there were none before, and frequently of the very worst kind, tending to break the beams across.

The dotted lines of this figure shew another position of the beam AD′. This makes a prodigious change, not only in the strain on AD′, but also in that on AC. Both of them are much increased; AG is almost doubled, and AF is four times greater than before. This addition was made to the figure, to shew what enormous strains may be produced by a very moderate force AE, when it is exerted on a very obtuse angle.

The 4th and 5th figures will assist the most uninstructed reader in conceiving how the very same strains AF, AG, are laid on these beams, by a weight simply hanging from a billet resting on A, pressing hard on AD, and also leaning a little on AC; or by an upright piece AE, joggled on the two beams AC, AD, and performing the office of an ordinary king-post. The reader will thus learn to call off his attention from the means by which the strains are produced, and learn to consider them abstractedly, merely as strains, in whatever situation he finds them, and from whatever cause they arise.

We presume that every reader will perceive, that the proportions of these strains will be precisely the same if every thing be inverted, and each beam be drawn or pulled in the opposite direction. In the same way that we have substituted a rope and weight in fig. 4. or a king-post in fig. 5. for the loaded beam BA of fig. 3. we might have substituted the framing of fig. 6. which is a very usual practice. In this framing, the batten DA is stretched by a force AG, and the piece AC is compressed by a force AF. It is evident, that we may employ a rope, or an iron rod hooked on at D, in place of the batten DA, and the strains will be the same as before.

This seemingly simple matter is still full of instruction; and we hope that the well-informed reader will pardon us, though we dwell a little longer on it for the sake of the young artist.

By changing the form of this framing, as in fig. 7. we produce the same strains as in the disposition represented by the dotted lines in fig. 3. The strains on both the battens AD, AC, are now greatly increased.

The same consequences result from an improper change of the position of AC. If it is placed as in fig. 8. the strains on both are vastly increased. In short, the rule is general; that the more open we make the angle against which the push is exerted, the greater are the strains which are brought on the struts or ties which form the sides of the angle.

The reader may not readily conceive the piece AC of fig. 8. as sustaining a compression; for the weight B appears to hang from AC as much as from AD. But his doubts will be removed by considering whether he could employ a rope in place of AC. He cannot: But AD may be exchanged for a rope. AC is therefore a strut, and not a tie.

In fig. 9. AD is again a strut, butting on the block D, and AC is a tie: and the batten AC may be replaced by a rope. While AD is compressed by the force AG, AC is stretched by the force AF.

If we give AC the position represented by the dotted lines, the compression of AD is now AG′, and the force stretching AC′ is now AF′; both much greater than they were before. This disposition is analogous to fig. 8. and to the dotted lines in fig. 3. Nor will the young artist have any doubts of AC′ being on the stretch, if he consider whether AD can be replaced by a rope. It cannot, but AC′ may; and it is therefore not compressed, but stretched.

In fig. 10. all the three pieces, AC, AD, and AB, are ties, on the stretch. This is the complete inversion of fig. 3.; and the dotted position of AC′ induces the same changes in the forces AF′, AG′, as in fig. 3.

Thus have we gone over all the varieties which can happen in the bearings of three pieces on one point. All calculations about the strength of carpentry are reduced to this case: for when more ties or braces meet in a point (a thing that rarely happens), we reduce them to three, by substituting for any two the force which results from their combination, and then combining this with another; and so on.

The young artist must be particularly careful not to mistake the kind of strain that is exerted on any piece of the framing, and suppose a piece to be a brace which is really a tie. It is very easy to avoid all mistakes in this matter by the following rule, which has no exception.

8
Rule for distinguishing the cases of compression and extension.

Take notice of the direction in which the piece acts from which the strain proceeds. Draw a line in that direction *from* the point on which the strain is exerted; and let its length (measured on some scale of equal parts) express the magnitude of this action in pounds, hundreds, or tons. From its *remote* extremity draw lines parallel to the pieces on which the strain is exerted. The line parallel to one piece will necessarily cut the other, or its direction produced: If it cut the piece itself, that piece is compressed by the strain, and it is performing the office of a strut or brace: if it cut its direction produced, the piece is stretched, and it is a tie. In short, the strains on the pieces AC, AD, are to be estimated in the direction of the points F and G *from* the strained point A. Thus, in fig. 3. the upright piece BA, loaded with the weight B, presses the point A in the direction AE: so does the rope AB in the other figures, or the batten AB in fig. 5.

In general, if the straining piece is within the angle formed

formed by the pieces which are ſtrained, the ſtrains which they ſuſtain are of the oppoſite kind to that which it exerts. If it be puſhing, they are drawing; but if it be within the angle formed by their directions produced, the ſtrains which they ſuſtain are of the ſame kind. All the three are either drawing or preſſing. If the ſtraining piece lie within the angle formed by one piece and the produced direction of the other, its own ſtrain, whether compreſſion or extenſion, is of the ſame kind with that of the moſt remote of the other two, and oppoſite to that of the neareſt. Thus, in fig. 9. where AB is drawing, the remote piece AC is alſo drawing, while AD is puſhing or reſiſting compreſſion.

In all that has been ſaid on this ſubject, we have not ſpoken of any joints. In the calculations with which we are occupied at preſent, the reſiſtance of joints has no ſhare; and we muſt not ſuppoſe that they exert any force which tends to prevent the angles from changing. The joints are ſuppoſed perfectly flexible, or to be like compaſs joints; the pin of which only keeps the pieces together when one or more of the pieces draws or pulls. The carpenter muſt always ſuppoſe them all compaſs joints when he calculates the thruſts and draughts of the different pieces of his frames. The ſtrains on joints, and their power to produce or balance them, are of a different kind, and require a very different examination.

9
General expreſſion of the magnitude of the ſtrain.

Seeing that the angles which the pieces make with each other are of ſuch importance to the magnitude and the proportion of the excited ſtrains, it is proper to find out ſome way of readily and compendiouſly conceiving and expreſſing this analogy.

In general, the ſtrain on any piece is proportional to the ſtraining force. This is evident.

Secondly, the ſtrain on any piece AC is proportional to the ſine of the angle which the ſtraining force makes with the other piece directly, and to the ſine of the angle which the pieces make with each other inverſely.

For it is plain, that the three preſſures AE, AF, and AG, which are exerted at the point A, are in the proportion of the lines AE, AF, and FE (becauſe FE is equal to AG). But becauſe the ſides of a triangle are proportional to the ſines of the oppoſite angles, the ſtrains are proportional to the ſines of the angles AFE, AEF, and FAE. But the ſine of AFE is the ſame with the ſine of the angle CAD, which the two pieces AC and AD make with each other; and the ſine of AFE is the ſame with the ſine of EAD, which the ſtraining piece BA makes with the piece AC. Therefore we have this analogy, Sin. CAD : Sin. EAD = AE : AF, and $AF = AE \times \frac{\text{Sin. EAD}}{\text{Sin. CAD}}$.—Now the ſine of angles are moſt conveniently conceived as decimal fractions of the radius, which is conſidered as unity. Thus, *Sin.* 30° is the ſame thing with 0,5, or $\frac{1}{2}$; and ſo of others. Therefore, to have the ſtrain on AC, ariſing from any load AE acting in the direction AE, multiply AE by the ſine of EAD, and divide the product by the ſine of CAD.

This rule ſhews how great the ſtrains muſt be when the angle CAD becomes very open, approaching to 180 degrees. But when the angle CAD becomes very ſmall, its ſine (which is our diviſor) is alſo very ſmall; and we ſhould expect a very great quotient in this caſe alſo. But we muſt obſerve, that in this caſe the ſine of EAD is alſo very ſmall; and this is our multiplier. In ſuch a caſe, the quotient cannot exceed unity.

But it is unneceſſary to conſider the calculation by the tables of ſines more particularly. The angles are ſeldom known any otherwiſe but by drawing the figure of the frame of carpentry. In this caſe, we can always obtain the meaſures of the ſtrains from the ſame ſcale, with equal accuracy, by drawing the parallelogram AFCG.

10
Strains propagated to the points of ſupport.

Hitherto we have conſidered the ſtrains excited at A only as they affect the pieces on which they are exerted. But the pieces, in order to ſuſtain, or be ſubject to, any ſtrain, muſt be ſupported at their ends C and D; and we may conſider them as mere intermediums, by which theſe ſtrains are made to act on thoſe points of ſupport: Therefore AF and AG are alſo meaſures of the forces which preſs or pull at C and D. Thus we learn the ſupports which muſt be found for theſe points. Theſe may be infinitely various. We ſhall attend only to ſuch as ſomehow depend on the framing itſelf.

11
Action of a ſtraining beam.

Such a ſtructure as fig. 11. very frequently occurs, where a beam BA is ſtrongly preſſed to the end of another beam AD, which is prevented from yielding, both becauſe it lies on another beam HD, and becauſe its end D is hindered from ſliding backwards. It is indifferent from what this preſſure ariſes: we have repreſented it as owing to a weight hung on at B, while B is withheld from yielding by a rod or rope hooked to the wall. The beam AD may be ſuppoſed at full liberty to exert all its preſſure on D, as if it were ſupported on rollers lodged in the beam HD; but the loaded beam BA preſſes both on the beam AD and on HD. We wiſh only to know what ſtrain is borne by AD?

All bodies act on each other in the direction perpendicular to their touching ſurfaces; therefore the ſupport given by HD is in a direction perpendicular to it. We may therefore ſupply its place at A by a beam AC, perpendicular to HD, and firmly ſupported at C. In this caſe, therefore, we may take AE, as before, to repreſent the preſſure exerted by the loaded beam, and draw EG perpendicular to AD, and EF parallel to it, meeting the perpendicular AC in F. Then AG is the ſtrain compreſſing AD, and AF is the preſſure on the beam HD.

12
The form of the abutting joint of no great importance.

It may be thought, that ſince we aſſume as a principle that the mutual preſſures of ſolid bodies are exerted perpendicular to their touching ſurfaces, this balance of preſſures, in framings of timbers, depends on the directions of their butting joints: but it does not, as will readily appear by conſidering the preſent caſe. Let the joint or abutment of the two pieces BA, AD be mitred, in the uſual manner, in the direction *f* A *f t*. Therefore, if A *e* be drawn perpendicular to A *f*, it will be the direction of the actual preſſure exerted by the loaded beam BA on the beam AD. But the reaction of AD, in the oppoſite direction A *t*, will not balance the preſſure of BA; becauſe it is not in the direction preciſely oppoſite. BA will therefore ſlide along the joint, and preſs on the beam HD. AE repreſents the load on the mitre joint A. Draw E *e* perpendicular to A *e*, and E *f* parallel to it. The preſſure AE will be balanced by the reactions *e* A and *f* A: or, the

the preffure AE produces the preffures A *e* and A *f*; of which A *f* muft be refifted by the beam HD, and A *e* by the beam AD. The preffure A *f* not being perpendicular to HD, cannot be fully refifled by it; becaufe (by our affumed principle) it reacts only in a direction perpendicular to its furface. Therefore draw *fp*, *fi* parallel to HD, and perpendicular to it. The preffure A *f* will be refifted by HD with the force *p* A; but there is required another force *i* A, to prevent the beam BA from flipping outwards. This muft be furnifhed by the reaction of the beam DA.—In like manner, the other force A *e* cannot be fully refifted by the beam AD, or rather by the prop D, acting by the intervention of the beam; for the action of that prop is exerted through the beam in the direction DA. The beam AD, therefore, is preffed to the beam HD by the force A *e*, as well as by A *f*. To find what this preffure on HD is, draw *eg* perpendicular to HD, and *eo* parallel to it, cutting EG in *r*. The forces *g* A and *o* A will refift, and balance A *e*.

Thus we fee, that the two forces A *e* and A *f*, which are equivalent to AE, are equivalent alfo to A *p*, A *i*, A *o*, and A *g*. But becaufe A *f* and *e* E are equal and parallel, and E *r* and *fi* are alfo parallel, as alfo *er* and *fp*, it is evident, that *if* is equal to *r* E, or to *o* F, and *i* A is equal to *re*, or to G *g*. Therefore the four forces A *g*, A *o*, A *p*, A *i*, are equal to AG and AF. Therefore AG is the compreffion of the beam AD, or the force preffing it on D, and A F is the force preffing it on the beam HD. The proportion of thefe preffures, therefore, is not affected by the form of the joint.

This remark is important; for many carpenters think the form and direction of the butting joint of great importance; and even the theorift, by not profecuting the general principle through *all* its confequences, may be led into an error. The form of the joint is of no importance, in as far as it affects the ftrains in the direction of the beams; but it is often of great confequence, in refpect to its own firmnefs, and the effect it may have in bruifing the piece on which it acts, or being crippled by it.

13 Origin of the ftrain on a tie-beam.

The fame compreffion of AB, and the fame thruft on the point D by the intervention of AD, will obtain, in whatever way the original preffure on the end A is produced. Thus fuppofing that a chord is made faft at A, and pulled in the direction AE, and with the fame force, the beam AD will be equally compreffed, and the prop D muft react with the fame force.

But it often happens that the obliquity of the preffure on AD, inftead of compreffing it, ftretches it; and we defire to know what tenfion it fuftains. Of this we have a familiar example in a common roof. Let the two rafters AC, AD (fig. 12.), prefs on the tie-beam DC. We may fuppofe the whole weight to prefs vertically on the ridge A, as if a weight B were hung on there. We may reprefent this weight by the portion A *b* of the vertical or plumb line, intercepted between the ridge and the beam. Then drawing *bf* and *bg* parallel to AD and AC, A *g* and A *f* will reprefent the preffures on AC and AD. Produce AC till CH be equal to A *f*. The point C is forced out in this direction, and with a force reprefented by this line. As this force is not perpendicularly acrofs the beam, it evidently ftretches it; and this extending force muft be withftood by an equal force pulling it in the oppofite direction. This muft arife from a fimilar oblique thruft of the oppofite rafter on the other end D. We concern ourfelves only with this extenfion at prefent; but we fee that the cohefion of the beam does nothing but fupply the balance to the extending forces. It muft ftill be fupported externally, that it *may refift*, and, by refifting obliquely, be ftretched. The points C and D are fupported on the walls, which they prefs in the directions CK and DO, parallel to A *b*. If we draw HK parallel to DC, and HI parallel to CK (that is, to A *b*), meeting DC produced in I, it follows from the compofition of forces, that the point C would be fupported by the two forces KC and IC. In like manner, making DN = A *g*, and completing the parallelogram DMNO, the point D would be fupported by the forces OD and MD. If we draw *go* and *fk* parallel to DC, it is plain that they are equal to NO and CK, while A *o* and A *k* are equal to DO and CK, and A *b* is equal to the fum of DO and CK (becaufe it is equal to A *o* + A *k*). The weight of the roof is equal to its vertical preffure on the walls.

Thus we fee, that while a preffure on A, in the direction A *b*, produces the ftrains A *f* and A *g*, on the pieces AC and AD, it alfo excites a ftrain CI or DM in the piece DC. And this completes the mechanifm of a frame; for all derive their efficacy from the triangles of which they are compofed, as will appear more clearly as we proceed.

14 External action of a frame.

But there is more to be learned from this. The confideration of the ftrains on the two pieces AD and AC, by the action of a force at A, only fhewed them as the means of propagating the fame ftrains in their own direction to the points of fupport. But, by adding the ftrains exerted in DC, we fee that the frame becomes an intermedium, by which exertions may be made on other bodies, in certain directions and proportions; fo that this frame may become part of a more complicated one, and, as it were, an element of its conftitution. It is worth while to afcertain the proportion of the preffures CK and DO, which are thus exerted on the walls. The fimilarity of triangles gives the following analogies:

DO : DM = A *b* : *b* D
CI, or DM : CK = C *b* : A *b*
Therefore DO : CK = C *b* : *b* D.

Or, *the preffures on the points* C *and* D, *in the direction of the ftraining force* A *b*, *are reciprocally proportional to the portions of* DC *intercepted by* A *b*.

Alfo, fince A *b* is = DO + CK, we have
A *b* : CK = C *b* + *b* D (or CD) : *b* D, and
A *b* : DO = C D : *b* C.

In general, any two of the three parallel forces A *b*, DO, CK, are to each other in the reciprocal proportion of the parts of CD, intercepted between their directions and the direction of the third.

And this explains a ftill more important office of the frame ADC. If one of the points, fuch as D, be fupported, an external power acting at A, in the direction A *b*, and with an intenfity which may be meafured by A *b*, may be fet in equilibrio, with another acting at C, in the direction CL, oppofite to CK or A *b*, and with an intenfity reprefented by CK: for fince the preffure CH is partly withftood by the force IC, or the firmnefs of the beam DC fupported at D, the force KC will complete the balance. When we do not attend to the fupport

fupport at D, we conceive the force A b to be balanced by KC, or KC to be balanced by A b. And, in like manner, we may neglect the fupport or force acting at A, and confider the force DO as balanced by CK.

15 It becomes a lever.

Thus our frame becomes a lever, and we are able to trace the interior mechanical procedure which gives it its efficacy: it is by the intervention of the forces of cohefion, which connect the points to which the external forces are applied with the fupported point or fulcrum, and with each other.

Thefe ftrains or preffures A b, DO, and CK, not being in the directions of the beams, may be called *tranfverfe*. We fee that by their means a frame of carpentry may be confidered as a folid body: but the example which brought this to our view is too limited for explaining the efficacy which may be given to fuch conftructions. We fhall therefore give a general propofition, which will more diftinctly explain the procedure of nature, and enable us to trace the ftrains as they are propagated through all the parts of the moft complicated framing, finally producing the exertion of its moft diftant points.

16 General propofition.

We prefume that the reader is now pretty well habituated to the conception of the ftrains as they are propagated along the lines joining the points of a frame, and we fhall therefore employ a very fimple figure.

Let the ftrong lines ACBD (fig. 13.) reprefent a frame of carpentry. Suppofe that it is pulled at the point A by a force acting in the direction AE, but that it refts on a fixed point C, and that the other extreme point B is held back by a power which refifts in the direction BF: It is required to determine the proportion of the ftrains excited in its different parts, the proportion of the external preffures at A and B, and the preffure which is produced on the obftacle or fulcrum C?

It is evident that each of the external forces at A and B tend one way, or to one fide of the frame, and that each would caufe it to turn round C if the other did not prevent it; and that if, notwithftanding their action, it is turned neither way, the forces in actual exertion are in equilibrio by the intervention of the frame. It is no lefs evident that thefe forces concur in preffing the frame on the prop C. Therefore, if the piece CD were away, and if the joints C and D be perfectly flexible, the pieces CA, CB would be turned round the prop C, and the pieces AD, DB would alfo turn with them, and the whole frame change its form. This fhews, by the way, and we defire it to be carefully kept in mind, that the firmnefs or ftiffnefs of framing depends entirely on the triangles bounded by beams which are contained in it. An open quadrilateral may always change its fhape, the fides revolving round the angles. A quadrilateral may have an infinity of forms, without any change of its fides, by merely pufhing two oppofite angles towards each other, or drawing them afunder. But when the three fides of a triangle are determined, its fhape is alfo invariably determined; and if two angles be held faft, the third cannot be moved. It is thus that, by inferting the bar CD, the figure becomes unchangeable; and any attempt to change it by applying a force to an angle A, immediately excites forces of attraction or repulfion between the particles of the ftuff which form its fides. Thus it happens, in the prefent inftance, that a change of fhape is prevented by the bar CD. The power at A preffes its end againft the prop; and in doing this it puts the bar AD on the ftretch, and alfo the bar DB. Their places might therefore be fupplied by cords or metal wires. Hence it is evident that DC is compreffed, as is alfo AC: and, for the fame reafon, CB is alfo in a ftate of compreffion; for either A or B may be confidered as the point that is impelled or withheld. Therefore DA and DB are ftretched, and are refifting with attractive forces. DC and CB are compreffed, and are refifting with repulfive forces. DB is alfo acting with repulfive forces, being compreffed in like manner: and thus the fupport of the prop, combined with the firmnefs of DC, puts the frame ADBC into the condition of the two frames in fig. 8. and fig. 9. Therefore the external force at A is really in equilibrio with an attracting force acting in the direction AD, and a repulfive force acting in the direction AK. And fince all the connecting forces are mutual and equal, the point D is pulled or drawn in the direction DA. The condition of the point B is fimilar to that of A, and D is alfo drawn in the direction DB. Thus the point D, being urged by the forces in the directions DA and DB, preffes the beam DC on the prop, and the prop refifts in the oppofite direction. Therefore the line DC is the diagonal of the parallelogram, whofe fides have the proportion of the forces which connect D with A and B. This is the principle on which the reft of our inveftigation proceeds. We may take DC as the reprefentation and meafure of their joint effect. Therefore draw CH, CG, parallel to DA, DB. Draw HL, GO, parallel to CA, CB, cutting AE, BF in L and O, and cutting DA, DB in I and M. Complete the parallelograms ILKA, MONB. Then DG and AI are the equal and oppofite forces which connect A and D: for GD = CH, = AI. In like manner DH and BM are the forces which connect D and B.

The external force at A is in immediate equilibrio with the combined forces, connecting A with D and with C. AI is one of them: Therefore AK is the other; and AL is the compound force with which the external force at A is in immediate equilibrium. This external force is therefore equal and oppofite to AL. In like manner, the external force at B is equal and oppofite to BO; and AL is to BO as the external force at A to the external force at B. The prop C refifts with forces equal to thofe which are propagated to it from the points D, A, and C. Therefore it refifts with forces CH, CG, equal and oppofite to DG, DH; and it refifts the compreffions KA, NB, with equal and oppofite forces C k, C n. Draw $k\,l$, $n\,o$ parallel to AD, BD, and draw C lQ, C o P: It is plain that lCHl is a parallelogram equal to KAIL, and that C l is equal to AL. In like manner C o is equal to BO. Now the forces C k, CH, exerted by the prop, compofe the force C l; and C n, CG compofe the force C o. Thefe two forces C l, C o are equal and parallel to AL and BO; and therefore they are equal and oppofite to the external forces acting at A and B. But they are (primitively) equal and oppofite to the preffures (or at leaft the compounds of the preffures) exerted on the prop, by the forces propagated to C from A, D, and B. Therefore the preffures exerted on the prop are the fame as if the external forces were applied there in the fame directions as they are applied to A and

Fig 9.

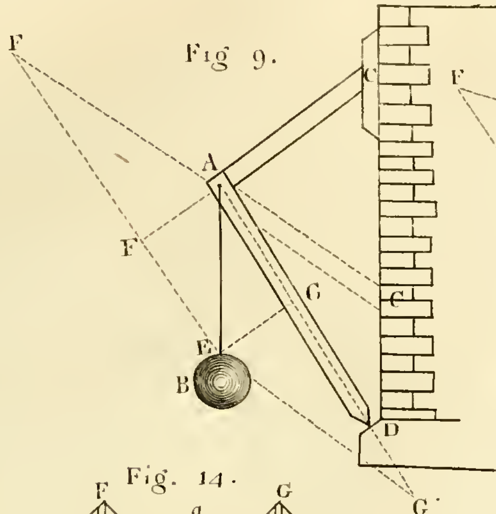


Fig. 10.

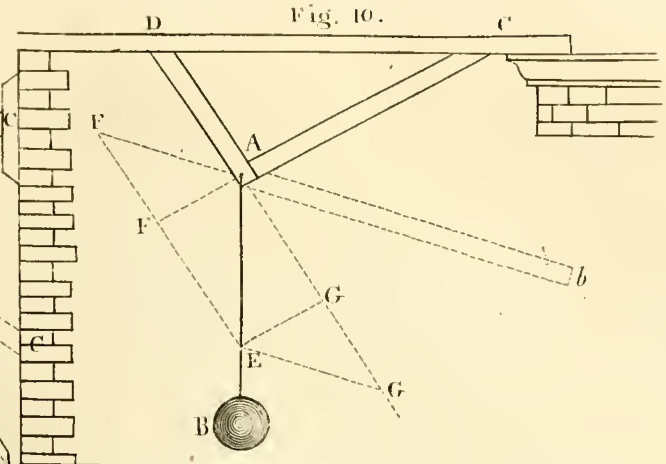

Fig. 14.

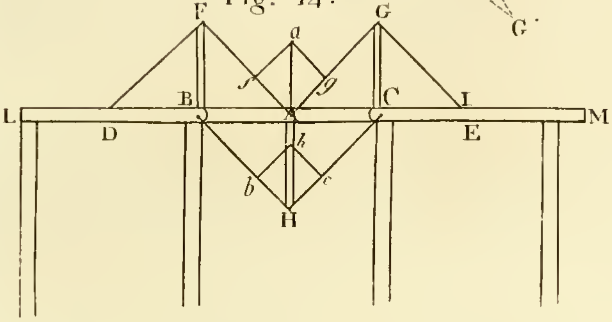

Fig. 15.

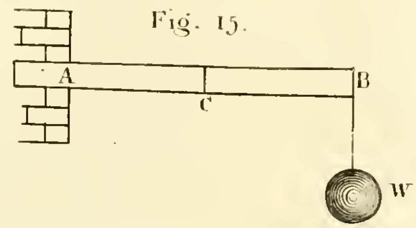

Fig. 11.

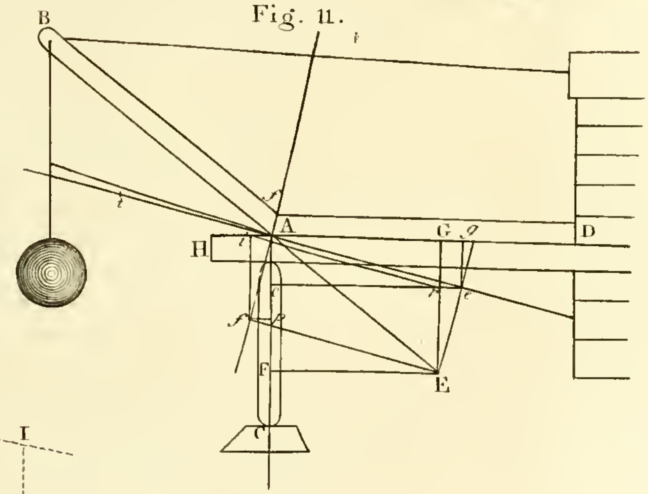

Fig. 12.

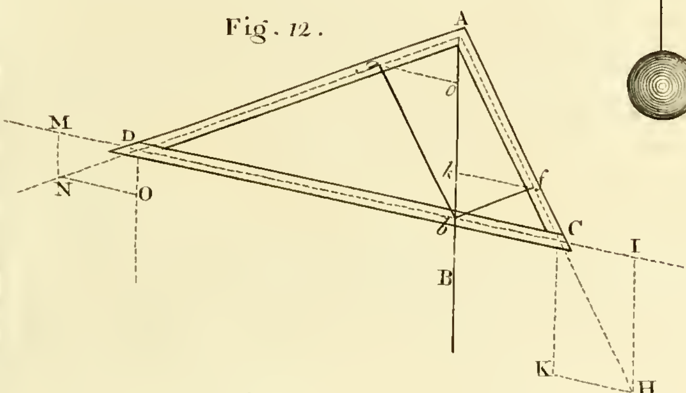

Fig. 16.

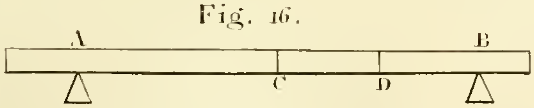

Fig. 13.

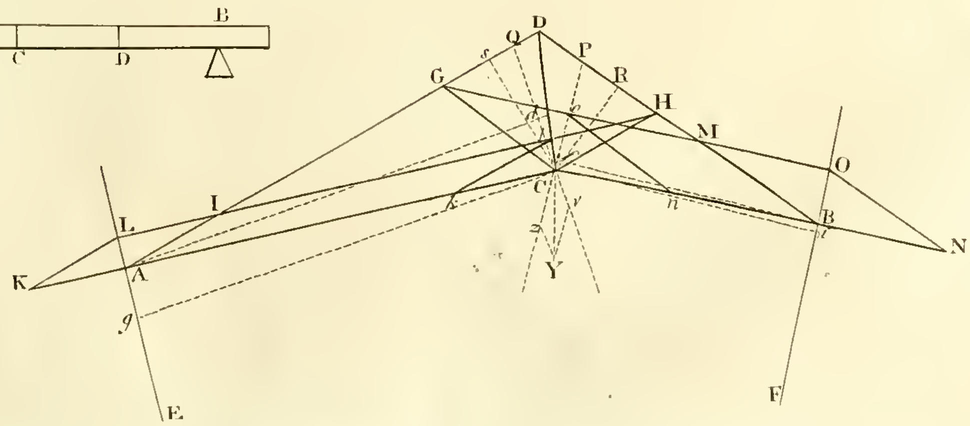

Bowes Sc.

and B. Now if we make CV, CZ equal to C *l* and C *o*, and complete the parallelogram CVYZ; it is plain that the force YC is in equilibrio with *l* C and *o* C. Therefore the preffures at A, C, and B, are fuch as would balance if applied to one point.

Laftly, in order to determine their proportions, draw CS and CR perpendicular to DA and DB. Alfo draw A *d*, B *f* perpendicular to CQ and CP; and draw C *g*, C *i* perpendicular to AE, BF.

The triangles CPR and BP *f* are fimilar, having a common angle P, and a right angle at R and *f*.

In like manner the triangles CQS and A Q *d* are fimilar. Alfo the triangles CHR, CGS are fimilar, by reafon of the equal angles at H and G, and the right angles at R and S. Hence we obtain the following analogies:

$$C o : CP = O n : PB, = CG : PB$$
$$CP : CR = PB : fB$$
$$CR : CS = CH : CG$$
$$CS : CQ = A d : AQ$$
$$CQ : C l = AQ : K l, = AQ : CH.$$

Therefore, by equality,

$$C o : C l = A d : f B$$
$$\text{or } BO : AL = C g : C i.$$

That is, the external forces are reciprocally proportional to the perpendiculars drawn from the prop on the lines of their direction (A).

17 Extenfive confequences.

This propofition (fufficiently general for our purpofe) is fertile in confequences, and furnifhes many ufeful inftructions to the artift. The ftrains LA, OB, CY, that are excited, occur in many, we may fay in all, framings of carpentry, whether for edifices or engines, and are the fources of their efficacy. It is alfo evident, that the doctrine of the tranfverfe ftrength of timber is contained in this propofition; for every piece of timber may be confidered as an affemblage of parts, connected by forces which act in the direction of the lines which join the ftrained points on the matter which lies between thofe points, and alfo act on the reft of the matter, exciting thofe lateral forces which produce the inflexibility of the whole. See *Strength of Materials*, Encycl.

Thus it appears that this propofition contains the principles which direct the artift to frame the moft powerful levers; to fecure uprights by fhores or braces, or by ties and ropes; to fecure fcaffoldings for the erection of fpires, and many other moft delicate problems of his art. He alfo learns, from this propofition, how to afcertain the ftrains that are produced, without his intention, by pieces which he intended for other offices, and which, by their tranfverfe action, put his work in hazard. In fhort, this propofition is the key to the fcience of his art.

We would now counfel the artift, after he has made the tracing of the ftrains and thrufts through the various parts of a frame familiar to his mind, and even amufed himfelf with fome complicated fancy framings, to read over with care the articles *Strength of Materials* and Roof in the *Encyclopædia*. He will now conceive its doctrines much more clearly than when he was confidering them as abftract theories. The mutual action of the woody fibres will now be eafily comprehended, and his confidence in the refults will be greatly increafed.

18 Decifion of a difputed and very important queftion.

There is a propofition (n° 19. in the article Roof) which has been called in queftion by feveral very intelligent perfons; and they fay that Belidor has demonftrated, in his Science des Ingenieurs, that a beam firmly fixed at both ends is not twice as ftrong as when fimply lying on the props, and that its ftrength is increafed only in the proportion of 2 to 3; and they fupport this determination by a lift of experiments recited by Belidor, which agree *precifely* with it. Belidor alfo fays, that Pitot had the fame refult in his experiments. Thefe are refpectable authorities: but Belidor's reafoning is any thing but demonftration; and his experiments are defcribed in fuch an imperfect manner, that we cannot build much on them. It is not faid in what manner the battens were fecured at the ends, any farther than that it was by *chevalets*. If by this word is meant a trefsle, we cannot conceive how they were employed; but we fee it fometimes ufed for a wedge or key. If the battens were wedged in the holes, their refiftance to fracture may be made what we pleafe: they may be loofe, and therefore refift little more than when fimply laid on the props. They may be (and probably were) wedged very faft, and bruifed or crippled.

Our propofition mentioned diftinctly the fecurity given to the ends of the beams. They were mortifed into remote pofts. Our *precife* meaning was, that they were fimply kept from rifing by thefe mortifes, but at full liberty to bend up between E and I, and between G and K. Our affertion was not made from theory

 alone

(A) The learned reader will perceive, that this analogy is precifely the fame with that of forces which are in equilibrio by the intervention of a lever. In fact, this whole frame of carpentry is nothing elfe than a *built* or *framed lever* in equilibrio. It is acting in the fame manner as a folid, which occupies the whole figure compreffed in the frame, or as a body of any fize and fhape whatever that will admit the three points of application A, C, and B. It is always in equilibrio in the cafe firft ftated; becaufe the preffure *produced* at B by a force applied to A is always fuch as balances it. The reader may alfo perceive, in this propofition, the analyfis or tracing of thofe internal mechanical forces which are indifpenfably requifite for the functions of a lever. The mechanicians have been extremely puzzled to find a legitimate demonftration of the equilibrium of a lever ever fince the days of Archimedes. Mr Vince has the honour of firft demonftrating, moft ingenioufly, the principle affumed by Archimedes, but without fufficient ground for *his* demonftration: but Mr Vince's demonftration is only a putting the mind into that perplexed ftate which makes it acknowledge the propofition, but without a clear perception of its truth. The difficulty has proceeded from the abftract notion of a lever, conceiving it as a mathematical line—inflexible, without reflecting how it is inflexible—for the very fource of this indifpenfable quality furnifhes the mechanical connection between the remote preffures and the fulcrum; and this fupplies the demonftration (without the leaft difficulty) of the defperate cafe of a ftraight lever urged by parallel forces. See Rotation, n° 11. *Encycl.*

alone (although we think the reafoning incontrovertible), but was agreeable to numerous experiments made in thofe precife circumftances. Had we mortifed the beams firmly into two very ftout pofts, which could not be drawn nearer to each other by bending, the beam would have borne a *much* greater weight, as we have verified by experiment. We hope that the following mode of conceiving this cafe will remove all doubts.

Let LM be a long beam (fig. 14.) divided into fix equal parts, in the points D, B, A, C, E. Let it be firmly fupported at L, B, C, M. Let it be cut thro' at A, and have compafs joints at B and C. Let FB, GC be two equal uprights, refting on B and C, but without any connection. Let AH be a fimilar and equal piece, to be occafionally applied at the feam A. Now let a thread or wire AGE be extended over the piece GC, and made faft at A, G, and E. Let the fame thing be done on the other fide of A. If a weight be now laid on at A, the wires AFD, AGE will be ftrained, and may be broken. In the inftant of fracture we may fuppofe their ftrains to be reprefented by A *f* and A *g*. Complete the parallelogram, and A *a* is the magnitude of the weight. It is plain that nothing is concerned here but the cohefion of the wires; for the beam is fawed through at A, and its parts are perfectly moveable round B and C.

Inftead of this procefs apply the piece AH below A, and keep it there by ftraining the fame wire BHC over it. Now lay on a weight. It muft prefs down the ends of BA and CA, and caufe the piece AH to ftrain the wire BHC. In the inftant of fracture of *the fame* wire, its refiftances H *b* and H *c* muft be equal to A *f* and A *g*, and the weight *b* H which breaks them muft be equal to A *a*.

Laftly employ all the three pieces FB, AH, GC, with the fame wire attached as before. There can be no doubt but that the weight which breaks all the four wires muft be $= a\text{A} + b\text{H}$, or twice A *a*.

The reader cannot but fee that the wires perform the very fame office with the fibres of an entire beam LM held faft in the four holes D, B, C, and E, of fome upright pofts.

In the experiments for verifying this, by breaking flender bars of fine deal, we get complete demonftration, by meafuring the curvatures produced in the parts of the beam thus held down, and comparing them with the curvature of a beam fimply laid on the props B and C: and there are many curious inferences to be made from thefe obfervations, but we have not room for them in this place.

19 The beft manner of framing purlins.

We may obferve, by the way, that we learn from this cafe, that purlins are able to carry twice the load when notched into the rafters that they carry when mortifed into them, which is the moft ufual manner of framing them. So would the binding joifts of floors; but this would double the thicknefs of the flooring. But this method fhould be followed in every poffible cafe, fuch as breaft fummers, lintels over feveral pillars, &c. Thefe fhould never be cut off and mortifed into the fides of every upright; numberlefs cafes will occur which fhew the importance of the maxim.

We muft here remark, that the proportion of the fpaces BC and CM, or BC and LB, has a very fenfible effect on the ftrength of the beam BC; but we have not yet fatisfied our minds as to the *rationale* of this effect. It is undoubtedly connected with the ferpentine form of the curve of the beam before fracture. This fhould be attended to in the conftruction of the fprings of carriages. Thefe are frequently fupported at a middle point (and it is an excellent practice), and there is a certain proportion which will give the eafieft motion to the body of the carriage. We alfo think that it is connected with that deviation from the beft theory obfervable in Buffon's experiments on various lengths of the fame fcantling. The force of the beams diminifhed much more than in the inverfe proportion of their lengths.

20 Ties are in general better than ftruts.

We have feen that it depends entirely on the pofition of the pieces in refpect of their points of ultimate fupport, and of the direction of the external force which produces the ftrains, whether any particular piece is in a ftate of extenfion or of compreffion. The knowledge of this circumftance may greatly influence us in the choice of the conftruction. In many cafes we may fubftitute flender iron rods for maffive beams, when the piece is to act the part of a tie. But we muft not invert this difpofition; for when a piece of timber acts as a ftrut, and is in a ftate of compreffion, it is next to certain that it is not equally compreffible in its oppofite fides through the whole length of the piece, and that the compreffing force on the abutting joint is not acting in the moft equable manner all over the joint. A very trifling inequality in either of thefe circumftances (efpecially in the firft) will comprefs the beam more on one fide than on the other. This cannot be without the beam's bending, and becoming concave on that fide on which it is moft compreffed. When this happens, the frame is in danger of being crufhed, and foon going to ruin. It is therefore indifpenfably neceffary to make ufe of beams in all cafes where ftruts are required of confiderable length, rather than of metal rods of flender dimenfions, unlefs in fituations where we can effectually prevent their bending, as in truffing a girder internally, where a caft iron ftrut may be firmly cafed in it, fo as not to bend in the fmalleft degree. In cafes where the preffures are enormous, as in the very oblique ftruts of a centre or arch frame, we muft be particularly cautious to do nothing which can facilitate the compreffion of either fide. No mortifes fhould be cut near to one fide; no lateral preffures, even the flighteft, fhould be allowed to touch it. We have feen a pillar of fir 12 inches long and one inch in fection, when loaded with three tons, fnap in an inftant when preffed on one fide by 16 pounds, while another bore $4\frac{1}{2}$ tons without hurt, becaufe it was inclofed (loofely) in a ftout pipe of iron.

In fuch cafes of enormous compreffion, it is of great importance that the compreffing force bear equally on the whole abutting furface. The German carpenters are accuftomed to put a plate of lead over the joint. This prevents, in fome meafure, the penetration of the end fibres. Mr Perronet, the celebrated French architect, formed his abutments into arches of circles, the centre of which was the remote end of the ftrut. By this contrivance the unavoidable change of form of the triangle made no partial bearing of either angle of the abutment. This always has a tendency to fplinter off the heel of the beam where it preffes ftrongeft. It is a very judicious practice.

When circumftances allow it, we fhould rather employ

ploy ties than ſtruts for ſecuring a beam againſt lateral ſtrains. When an upright pillar, ſuch as a flag ſtaff, a maſt, or the uprights of a very tall ſcaffolding, are to be ſhoared up, the dependence is more certain on thoſe braces that are ſtretched by the ſtrain than on thoſe which are compreſſed. The ſcaffolding of the iron bridge near Sunderland had ſome ties very judiciouſly diſpoſed, and others with leſs judgment.

We ſhould proceed to conſider the tranſverſe ſtrains as they affect the various parts of a frame of carpentry; but we have very little to add to what has been ſaid already in the article *Strength of Materials* (Encycl.) and in the article Roof. What we ſhall add in this article will find a place in our occaſional remarks on different works. It may, however, be of uſe to recal to the reader's memory the following propoſitions.

21 General theorems concerning the relative ſtrength of beams.

1. When a beam AB (fig. 15.) is firmly fixed at the end A, and a ſtraining force acts perpendicularly to its length at any point B, the ſtrain occaſioned at any ſection C between B and A is proportional to CB, and may therefore be repreſented by the product W+CB; that is, by the product of the number of tons, pounds, &c. which meaſure the ſtraining force, and the number of feet, inches, &c. contained in CB. As the loads on a beam are eaſily conceived, we ſhall ſubſtitute this for any other ſtraining force.

2. If the ſtrain or load is uniformly diſtributed along any part of the beam lying beyond C (that is, further from A), the ſtrain at C is the ſame as if the load were all collected at the middle point of that part; for that point is the centre of gravity of the load.

3. The ſtrain on any ſection D of a beam AB (fig 16.) reſting freely on two props A and B, is $w \times \frac{AD \times DB}{AB}$ (ſee Roof, n° 19. and *Strength of Materials*, n° 92, &c. *Encycl*.). Therefore,

4. The ſtrain on the middle point, by a force applied there, is one-fourth of the ſtrain which the ſame force would produce, if applied to one end of a beam of the ſame length, having the other end fixed.

5. The ſtrain on any ſection C of a beam, reſting on two props A and B, occaſioned by a force applied perpendicularly to another point D, is proportional to the rectangle of the exterior ſegments, or is equal to $w \times \frac{AC \times DB}{AB}$. Therefore

The ſtrain at C occaſioned by the preſſure on D, is the ſame with the ſtrain at D occaſioned by the ſame preſſure on C.

6. The ſtrain on any ſection D, occaſioned by a load uniformly diffuſed over any part EF, is the ſame as if the two parts ED, DF of the load were collected at their middle points *e* and *f*. Therefore

The ſtrain on any part D, occaſioned by a load uniformly diſtributed over the whole beam, is one-half of the ſtrain that is produced when the ſame load is laid on at D; and

The ſtrain on the middle point C, occaſioned by a load uniformly diſtributed over the whole beam, is the ſame which half that load would produce if laid on at C.

7. A beam ſupported at both ends on two props B and C (fig. 14), will carry twice as much when the ends beyond the props are kept from riſing, as it will carry when it reſts looſely on the props.

8. Laſtly, the tranſverſe ſtrain on any ſection, occaſioned by a force applied obliquely, is diminiſhed in the proportion of the ſine of the angle which the direction of the force makes with the beam. Thus, if it be inclined to it in an angle of thirty degrees, the ſtrain is one-half of the ſtrain occaſioned by the ſame force acting perpendicularly.

On the other hand, the relative strength of a beam, or its power in any particular ſection to reſiſt any tranſverſe ſtrain, is proportional to the abſolute coheſion of the ſection directly, to the diſtance of its centre of effort from the axis of fracture directly, and to the diſtance from the ſtrained point inverſely.

Thus in a rectangular ſection of the beam, of which b is the breadth, d the depth (that is, the dimenſion in the direction of the ſtraining force), meaſured in inches, and f the number of pounds which one ſquare inch will juſt ſupport without being torn aſunder, we muſt have $f \times b \times d^2$, proportional to $w \times CB$ (fig. 15.) Or, $f \times b \times d^2$, multiplied by ſome number m, depending on the nature of the timber, muſt be equal to $w \times CB$. Or, in the caſe of the ſection C of fig. 16. that is ſtrained by the force w applied at D, we muſt have $m \times f b d^2 = w \times \frac{AC \times DB}{AB}$. Thus if the beam is of ſound oak, m is very nearly $= \frac{1}{9}$ (ſee *Strength of Materials*, n° 116, Encycl.). Therefore we have $\frac{f b d^2}{9} = w \times \frac{AC \times CB}{AB}$.

Hence we can tell the preciſe force w which any ſection C can juſt reſiſt when that force is applied in any way whatever. For the above mentioned formula gives $w = \frac{f b d^2}{9 CB}$, for the caſe repreſented by fig. 15. But the caſe repreſented in fig. 16. having the ſtraining force applied at D, gives the ſtrain at C $(= w) = f \times \frac{b d^2 \times AB}{9 AC \times CB}$.

Example. Let an oak beam, four inches ſquare, reſt freely on the props A and B, ſeven feet apart, or 84 inches. What weight will it juſt ſupport at its middle point C, on the ſuppoſition that a ſquare inch rod will juſt carry 16,000 pounds, pulling it aſunder?

The formula becomes $w = \frac{16000 \times 4 \times 16 \times 84}{9 \times 42 \times 42}$, or $w = \frac{86016000}{15876}$, $= 5418$ pounds. This is very near what was employed in Buffon's experiment, which was 5312.

Had the ſtraining force acted on a point D, half way between C and B, the force ſufficient to break the beam at C would be $= \frac{16000 \times 4 \times 16 \times 84}{9 \times 42 \times 21} = 10836$ lbs.

Had the beam been found red fir, we muſt have taken $f = 10,000$ nearly, and m nearly 8; for although fir be leſs coheſive than oak in the proportion of 5 to 8 nearly, it is leſs compreſſible, and its axis of fracture is therefore nearer to the concave ſide.

22 Of joints.

Having conſidered at ſufficient length the ſtrains of of different kinds which arise from the form of the parts of a frame of carpentry, and the direction of the external forces which act on it, whether considered as impelling or as supporting its different parts, we must now proceed to consider the means by which this form is to be secured, and the connections by which those strains are excited and communicated.

The joinings practised in carpentry are almost infinitely various, and each has advantages which make it preferable in some circumstances. Many varieties are employed merely to please the eye. We do not concern ourselves with these: Nor shall we consider those which are only employed in connecting small works, and can never appear on a great scale; yet even in some of these, the skill of the carpenter may be discovered by his choice; for in all cases, it is wise to make every, even the smallest, part of his work as strong as the materials will admit. He will be particularly attentive to the changes which will necessarily happen by the shrinking of timber as it dries, and will consider what dimensions of his framings will be affected by this, and what will not; and will then dispose the pieces which are less essential to the strength of the whole, in such a manner that their tendency to shrink shall be in the same direction with the shrinking of the whole framing. If he do otherwise, the seams will widen, and parts will be split asunder. He will dispose his boardings in such a manner as to contribute to the stiffness of the whole, avoiding at the same time the giving them positions which will produce lateral strains on truss beams which bear great pressures; recollecting, that although a single board has little force, yet many united have a great deal, and may frequently perform the office of very powerful struts.

Our limits confine us to the joinings which are most essential for connecting the parts of a single piece of a frame when it cannot be formed of one beam, either for want of the necessary thickness or length; and the joints for connecting the different sides of a trussed frame.

23 Of building up beams. Much ingenuity and contrivance has been bestowed on the manner of building up a great beam of many thicknesses, and many singular methods are practised as great nostrums by different artists; but when we consider the manner in which the cohesion of the fibres performs its office, we will clearly see that the simplest are equally effectual with the most refined, and that they are less apt to lead us into false notions of the strength of the assemblage.

24 Building up a girder or lever. Thus, were it required to build up a beam for a great lever or a girder, so that it may act nearly as a beam of the same size of one log—it may either be done by plain joggling, as in fig. 17. A, or by scarfing as in fig. 17. B or C. If it is to act as a lever, having the gudgeon on the lower side at C, we believe that most artists will prefer the form B and C; at least this has been the case with nine-tenths of those to whom we have proposed the question. The best informed only hesitated; but the ordinary artists were all confident in its superiority; and we found their views of the matter very coincident. They considered the upper piece as grasping the lower in its hooks; and several imagined that, by driving the one very tight on the other, the beam would be stronger than an entire log: but if we attend carefully to the internal procedure in the loaded lever, we shall find the upper one clearly the strongest. If they are formed of equal logs, the upper one is thicker than the other by the depth of the joggling or scarfing, which we suppose to be the same in both; consequently, if the cohesion of the fibres in the intervals is able to bring the uppermost filaments into full action, the form A is stronger than B, in the proportion of the greater distance of the upper filaments from the axis of the fracture: this may be greater than the difference of the thickness, if the wood is very compressible. If the gudgeon be in the middle, the effect, both of the joggles and the scarfings, is considerably diminished; and if it is on the upper side, the scarfings act in a very different way. In this situation, if the loads on the arms are also applied to the upper side, the joggled beam is still more superior to the scarfed one. This will be best understood by resolving it in imagination into a trussed frame. But when a gudgeon is thus put on that side of the lever which grows convex by the strain, it is usual to connect it with the rest by a powerful strap, which embraces the beam, and causes the opposite point to become the resisting point. This greatly changes the internal actions of the filaments, and, in some measure, brings it into the same state as the first, with the gudgeon below. Were it possible to have the gudgeon on the upper side, and to bring the whole into action without a strap, it would be the strongest of all; because, in general, the resistance to compression is greater than to extension. In every situation the joggled beam has the advantage; and it is the easiest executed.

25 Joggling preferable to scarfing. We may frequently gain a considerable accession of strength by this building up of a beam; especially if the part which is stretched by the strain be of oak, and the other part be fir. Fir being so much superior to oak as a pillar (if Musschenbroek's experiments may be confided in), and oak so much preferable as a tie, this construction seems to unite both advantages. But we shall see much better methods of making powerful levers, girders, &c. by trussing.

Observe, that the efficacy of both methods depends entirely on the difficulty of causing the piece between the cross joints to slide along the timber to which it adheres. Therefore, if this be moderate, it is wrong to make the notches deep; for as soon as they are so deep that their ends have a force sufficient to push the slice along the line of junction, nothing is gained by making them deeper; and this requires a greater expenditure of timber.

Scarfings are frequently made oblique, as in fig. 18. but we imagine that this is a bad practice. It begins to yield at the point, where the wood is crippled and splintered off, or at least bruised out a little: as the pressure increases, this part, by squeezing broader, causes the solid parts to rise a little upwards, and gives them some tendency, not only to push their antagonists along the base, but even to tear them up a little. For similar reasons, we disapprove of the favourite practice of many artists, to make the angles of their scarfings acute, as in fig. 19. This often causes the two pieces to tear each other up. The abutments should always be perpendicular to the directions of the pressures. Lest it should be forgotten in its proper place, we may extend this injunction also to the abutments of different pieces of a frame, and recommend it to the artist even

to

to attend to the ſhrinking of the timbers by drying. When two timbers abut obliquely, the joint ſhould be moſt full at the obtuſe angle of the end; becauſe, by drying that angle grows more obtuſe, and the beam would then be in danger of ſplintering off at the acute angle.

26 We muſt not wedge too hard.

It is evident, that the niceſt work is indiſpenſably neceſſary in building up a beam. The parts muſt abut on each other completely, and the ſmalleſt play or void takes away the whole efficacy. It is uſual to give the butting joints a ſmall taper to one ſide of the beam, ſo that they may require moderate blows of a maul to force them in, and the joints may be perfectly cloſe when the external ſurfaces are even on each ſide of the beam. But we muſt not exceed in the leaſt degree; for a very taper wedge has great force; and if we have driven the pieces together by very heavy blows, we leave the whole in a ſtate of violent ſtrain, and the abutments are perhaps ready to ſplinter off by a ſmall addition of preſſure. This is like too ſevere a proof for artillery; which, though not ſufficient to burſt the pieces, has weakened them to ſuch a degree, that the ſtrain of ordinary ſervice is ſufficient to complete the fracture. The *workman* is tempted to exceed in this, becauſe it ſmooths off and conceals all uneven ſeams; but he muſt be watched. It is not unuſual to leave ſome abutments open enough to admit a thin wedge reaching through the beam. Nor is this a bad practice, if the wedge is of materials which is not compreſſed by the driving or the ſtrain of ſervice. Iron would be preferable for this purpoſe, and for the joggles, were it not that by its too great hardneſs it cripples the fibres of timber to ſome diſtance. In conſequence of this, it often happens that, in beams which are ſubjected to deſultory and ſudden ſtrains (as in the levers of reciprocating engines), the joggles or wedges widen the holes, and work themſelves looſe: Therefore ſkilful engineers never admit them, and indeed as few bolts as poſſible, for the ſame reaſon: but when reſiſting a ſteady or dead pull, they are not ſo improper, and are frequently uſed.

Beams are built up, not only to increaſe their dimenſions in the direction of the ſtrain (which we have hitherto called their depth), but alſo to increaſe their breadth or the dimenſions perpendicular to the ſtrain. We ſometimes double the breadth of a girder which is thought too weak for its load, and where we muſt not increaſe the thickneſs of the flooring. The maſt of a great ſhip of war muſt be made bigger athwartſhip, as well as fore and aft. This is one of the niceſt problems of the art; and profeſſional men are by no means agreed in their opinions about it. We do not preſume to decide; and ſhall content ourſelves with exhibiting the different methods.

27 Building of maſts.

The moſt obvious and natural method is that ſhewn in fig. 20. It is plain that (independent of the connection of croſs bolts, which are uſed in them all when the beams are ſquare) the piece C cannot bend in the direction of the plane of the figure without bending the piece D along with it. This method is much uſed in the French navy; but it is undoubtedly imperfect. Hardly any two great trees are of equal quality, and ſwell or ſhrink alike. If C ſhrinks more than D, the feather of C becomes looſe in the groove wrought in D to receive it; and when the beam bends, the p[illegible] can ſlide on each other like the plates of a co[illegible]; and if the bending is in the direction $e\ f$, there is nothing to hinder this ſliding but the bolts, which ſoon work themſelves looſe in the bolt-holes.

28 Method uſed in the French Navy.

29 Another method.

Fig. 21. exhibits another method. The two halves of the beam are tabled into each other in the ſame manner as in fig. 17. It is plain that this will not be affected by the unequal ſwelling or ſhrinking, becauſe this is inſenſible in the direction of the fibres; but when bent in the direction $a\ b$, the beam is weaker than fig. 20. bent in the direction $e\ f$. Each half of fig. 20. has, in every part of its length, a thickneſs greater than half the thickneſs of the beam. It is the contrary in the alternate portions of the halves of fig. 21. When one of them is bent in the direction AB, it is plain that it drags the other with it by means of the croſs butments of its tables, and there can be no longitudinal ſliding. But unleſs the work is accurately executed, and each hollow completely filled up by the table of the other piece, there will be a lateral ſlide along the croſs joints ſufficient to compenſate for the curvature: and this will hinder the one from compreſſing or ſtretching the other in conformity to this curvature.

30 Its imperfection.

The imperfection of this method is ſo obvious, that it has ſeldom been practiſed; but it has been combined with the other, as is repreſented in fig. 22. where the beams are divided along the middle, and the tables in each half are alternate, and alternate alſo with the tables of the other half. Thus 1, 3, 4, are prominent, and 5, 2, 6, are depreſſed. This conſtruction evidently puts a ſtop to both ſlides, and obliges every part of both pieces to move together. $a\ b$ and $c\ d$ ſhow ſections of the built-up beam correſponding to AB and CD.

No more is intended in this practice by any intelligent artiſt, than the cauſing the two pieces to act together in all their parts, although the ſtrains may be unequally diſtributed on them. Thus, in a built-up girder, the binding joiſts are frequently mortiſed into very different parts of the two ſides. But many ſeem to aim at making the beam ſtronger than if it were of one piece; and this inconſiderate project has given riſe to many whimſical modes of tabling and ſcarfing, which we need not regard.

31 Britiſh method;

The practice in the Britiſh dock-yards is ſomewhat different from any of theſe methods. The pieces are tabled as in fig. 22. but the tables are not thin parallelopipeds, but thin priſms. The two outward joints or viſible ſeams are ſtraight lines, and the table n° 1. riſes gradually to its greateſt thickneſs in the axis. In like manner the hollow 5 for receiving the oppoſite table, ſinks gradually from the edge to its greateſt depth in the axis. Fig. 23. repreſents a ſection of a round piece of timber built up in this way, where the full line EFGH is the ſection correſponding to AB of fig. 22. and the dotted line EGFH is the ſection correſponding to CD.

This conſtruction, by making the external ſeam ſtraight, leaves no lodgment for water, and looks much fairer to the eye: but it appears to us that it does not give ſuch firm hold when the maſt is bent in the direction EH. The exterior parts are moſt ſtretched and moſt compreſſed by this bending; but there is hardly any abutment in the exterior parts of theſe tables. In the very axis, where the abutment is the firmeſt, there is little or no difference of extenſion and compreſſion.

But

But this construction has an advantage, which we imagine much more than compensates for these imperfections, at least in the particular case of a round mast: it will draw together by hooping incomparably better than any of the others. If the cavity be made somewhat too shallow for the prominence of the tables, and if this be done uniformly along the whole length, it will make a somewhat open seam; and this opening can be regulated with the utmost exactness from end to end by the plane. The heart of those vast trunks is very sensibly softer than the exterior circles: Therefore, when the whole is hooped, and the hoops hard driven, and at considerable intervals between each spell—we are confident that all may be compressed till the seam disappears; and then the whole makes one piece, *much* stronger than if it were an original log of that size, because the middle has become, by compression, as solid as the crust, which was naturally firmer, and resisted farther compression. We verified this beyond a doubt, by hooping a built stick of a timber which has this inequality of firmness in a remarkable degree, and it was nearly twice as strong as another of the same size.

Our mastmakers are not without their fancies and whims; and the manner in which our masts and yards are generally built up, is not near so simple as fig. 22.: but it consists of the same essential parts, acting in the very same manner, and derives all its efficacy from the principles which are here employed.

32 Attended with peculiar advantages.

This construction is particularly suited to the situation and office of a ship's mast. It has no bolts; or, at least, none of any magnitude, or that make very important parts of its construction. The most violent strains perhaps that it is exposed to, is that of twisting, when the lower yards are close braced up by the force of many men acting by a long lever. This form resists a twist with peculiar energy: it is therefore an excellent method for building up a great shaft for a mill. The way in which they are usually built up is by reducing a central log to a polygonal prism, and then filling it up to the intended size by *planting* pieces of timber along its sides, either spiking them down, or cocking them into it by a feather, or joggling them by slips of hard wood sunk into the central log and into the slips. *N. B.* Joggles of elm are sometimes used in the middle of the large tables of masts; and when sunk into the firm wood near the surface, they must contribute much to the strength. But it is very necessary to employ wood not much harder than the pine; otherwise it will soon enlarge its bed, and become loose; for the timber of these large trunks is very soft.

The most general reason for piecing a beam is to increase its length. This is frequently necessary, in order to procure tie-beams for very wide roofs. Two pieces must be scarfed together.—Numberless are the modes of doing this; and almost every master carpenter has his favorite nostrum. Some of them are very ingenious: But here, as in other cases, the most simple are commonly the strongest. We do not imagine that any, the most ingenious, is equally strong with a tie consisting of two pieces of the same scantling laid over each other for a certain length, and firmly bolted together. We acknowledge that this will appear an artless and clumsy tie-beam; but we only say that it will be stronger than any that is more artificially made up of the same thickness of timber. This, we imagine, will appear sufficiently certain.

33 Various methods of scarfing.

The simplest and most obvious scarfing (after the one now mentioned) is that represented in fig. 24. n° 1. and 2. If considered merely as two pieces of wood joined, it is plain that, as a tie, it has but half the strength of an entire piece, supposing that the bolts (which are the only connections) are fast in their holes. N° 2. requires a bolt in the middle of the scarf to give it that strength; and, in every other part, is weaker on one side or the other.

But the bolts are very apt to bend by the violent strain, and require to be strengthened by uniting their ends by iron plates; in which case it is no longer a wooden tie. The form of n° 1. is better adapted to the office of a pillar than n° 2.; especially if its ends be formed in the manner shewn in the elevation n° 3. By the sally given to the ends, the scarf resists an effort to bend it in that direction. Besides, the form of n° 2. is unsuitable for a post; because the pieces, by sliding on each other by the pressure, are apt to splinter off the tongue which confines their extremity.

Fig. 25. and 26. exhibit the most approved form of a scarf, whether for a tie or for a post. The key represented in the middle is not essentially necessary; the two pieces might simply meet square there. This form, without a key, needs no bolts (although they strengthen it greatly); but, if worked very true and close, and with square abutments, will hold together, and will resist bending in any direction. But the key is an ingenious and a very great improvement, and will force the parts together with perfect tightness. The same precaution must be observed that we mentioned on another occasion, not to produce a constant internal strain on the parts by overdriving the key. The form of fig. 25. is by far the best; because the triangle of 26. is much easier splintered off by the strain, or by the key, than the square wood of 25. It is far preferable for a post, for the reason given when speaking of fig. 24. n° 1. and n° 2. Both may be formed with a sally at the ends equal to the breadth of the key. In this shape fig. 25. is vastly well suited for joining the parts of the long corner posts of spires and other wooden towers. Fig. 25. n° 2. differs from n° 1. only by having three keys. The principle and the longitudinal strength are the same. The long scarf of n° 2. tightened by the three keys, enables it to resist a bending much better.

None of these scarfed tie-beams can have more than one-third of the strength of an entire piece, unless with the assistance of iron plates; for if the key be made thinner than one-third, it has less than one-third of the fibres to pull by.

We are confident, therefore, that when the heads of the bolts are connected by plates, the simple form of fig. 24. n° 1. is stronger than those more ingenious scarfings. It may be strengthened against lateral bending by a little tongue, or by a sally; but it cannot have both.

The strongest of all methods of piecing a tie-beam would be to set the parts end to end, and grasp them between other pieces on each side, as in fig. 27. This is what the ship-carpenter calls *fishing* a beam; and is a frequent practice for occasional repairs. Mr Perronet used it for the tie-beams or stretchers, by which he connected

nected the oppofite feet of a centre, which was yielding to its load, and had pufhed afide one of the piers above four inches. Six of thefe not only withftood a ftrain of 1800 tons, but, by wedging behind them, he brought the feet of the trufs $2\frac{1}{2}$ inches nearer. The ftretchers were 14 inches by 11 of found oak, and could have withftood three times that ftrain. Mr Perronet, fearing that the great length of the bolts employed to connect the beams of thefe ftretchers would expofe them to the rifk of bending, fcarfed the two fide pieces into the middle piece. The fcarfing was of the triangular kind *(Trait de Jupiter)*, and only an inch deep, each face being two feet long, and the bolt paffed through clofe to the angle.

In piecing the pump rods, and other wooden ftretchers of great engines, no dependence is had on fcarfing; and the engineer connects every thing by iron ftraps. We doubt the propriety of this, at leaft in cafes where the bulk of the wooden connection is not inconvenient. Thefe obfervations muft fuffice for the methods employed for connecting the parts of a beam; and we now proceed to confider what are more ufually called the joints of a piece of carpentry.

35 Square joints. Where the beams ftand fquare with each other, and the ftrains are alfo fquare with the beams, and in the plane of the frame, the common mortife and tenon is the moft perfect junction. A pin is generally put through both, in order to keep the pieces united, in oppofition to any force which tends to part them. Every carpenter knows how to bore the hole for this pin, fo that it fhall draw the tenon tight into the mortife, and caufe the fhoulder to butt clofe, and make neat work; and he knows the rifk of tearing out the bit of the tenon beyond the pin, if he draw it too much. We may juft obferve, that fquare holes and pins are much preferable to round ones for this purpofe, bringing more of the wood into action, with lefs tendency to fplit it. The fhip carpenters have an ingenious method of making long wooden bolts, which do not pafs completely through, take a very faft hold, though not nicely fitted to their holes, which they muft not be, left they fhould be crippled in driving. They

36 Foxtail wedging. call it *foxtail wedging*. They ftick into the point of the bolt a very thin wedge of hard wood, fo as to project a proper diftance: when this reaches the bottom of the hole by driving the bolt, it fplits the end of it, and fqueezes it hard to the fide. This may be practifed with advantage in carpentry. If the ends of the mortife are widened inwards, and a thin wedge be put into the end of the tenon, it will have the fame effect, and make the joint equal to a dovetail. But this rifks the fplitting the piece beyond the fhoulder of the tenon, which would be unfightly. This may be avoided as follows: Let the tenon T, fig. 28. have two *very* thin wedges *a* and *c* ftuck in near its angles, projecting equally: at a very fmall diftance within thefe, put in two fhorter ones *b*, *d*, and more within thefe if neceffary. In driving this tenon, the wedges *a* and *c* will take firft, and fplit off a thin flice, which will eafily bend without breaking. The wedges *b*, *d*, will act next, and have a fimilar effect, and the others in fucceffion. The thicknefs of all the wedges taken together muft be equal to the enlargement of the mortife toward the bottom.

When the ftrain is tranfverfe to the plane of the two beams, the principles laid down in nº 85, 86, of the article *Strength of Materials*, will direct the artift in placing his mortife. Thus the mortife in a girder for receiving the tenon of a binding joift of a floor fhould be as near the upper fide as poffible, becaufe the girder becomes concave on that fide by the ftrain. But as this expofes the tenon of the binding-joift to the rifk of being torn off, we are obliged to mortife farther down. The form (fig. 29.) generally given to this joint is extremely judicious. The floping part *a b* gives a very firm fupport to the additional bearing *c d*, without much weakening of the girder. This form fhould be copied in every cafe where the ftrain has a fimilar direction.

The joint that moft of all demands the careful attention of the artift, is that which connects the ends of beams, one of which pufhes the other very obliquely, putting it into a ftate of extenfion. The moft familiar inftance of this is the foot of a rafter preffing on the tie-beam, and thereby *drawing* it away from the other wall. When the direction is very oblique (in which cafe the extending ftrain is the greateft), it is difficult to give the foot of the rafter fuch a hold of the tie-beam as to bring many of its fibres into the proper action. There would be little difficulty if we could allow the end of the tie-beam to project to a fmall diftance beyond the foot of the rafter: but, indeed, the dimenfions which are given to tie-beams, for other reafons, are always fufficient to give enough of abutment when judicioufly employed. Unfortunately this joint is much expofed to failure by the effects of the weather. It is much expofed, and frequently perifhes by rot, or becomes fo foft and friable that a very fmall force is fufficient, either for pulling the filaments out of the tie-beam, or for crufhing them together. We are therefore obliged to fecure it with particular attention, and to avail ourfelves of every circumftance of conftruction. 37 Oblique mortife and tenon.

One is naturally difpofed to give the rafter a deep hold by a long tenon; but it has been frequently obferved in old roofs that fuch tenons break off. Frequently they are obferved to tear up the wood that is above them, and pufh their way through the end of the tie-beam. This in all probability arifes from the firft fagging of the roof, by the compreffion of the rafters and of the head of the king poft. The head of the rafter defcends, the angle with the tie-beam is diminifhed by the rafter revolving round its ftep in the tie-beam. By this motion the heel or inner angle of the rafter becomes a fulcrum to a very long and powerful lever much loaded. The tenon is the other arm, very fhort, and being ftill frefh, it is therefore very powerful. It therefore forces up the wood that is above it, tearing it out from between the cheeks of the mortife, and then pufhes it along. Carpenters have therefore given up long tenons, and give to the toe of the tenon a fhape which abuts firmly, in the direction of the thruft, on the folid bottom of the mortife, which is well fupported on the under fide by the wall plate. This form has the farther advantage of having no tendency to tear up the end of the mortife. This form is reprefented in fig. 30. The tenon has a fmall portion *a b* cut perpendicular to the furface of the tie-beam, and the reft *b c* is perpendicular to the rafter.

But if the tenon is not fufficiently ftrong (and it is not

not so strong as the rafter, which is thought not to be stronger than is necessary), it will be crushed, and then the rafter will shade out along the surface of the beam. It is therefore necessary to call in the assistance of the whole rafter. It is in this distribution of the strain among the various abutting parts that the varieties of joints and their merits chiefly consists. It would be endless to describe every nostrum, and we shall only mention a few that are most generally approved of.

38 Most approved forms.

The aim in fig. 31. is to make the abutments exactly perpendicular to the thrusts. It does this very precisely; and the share which the tenon and the shoulder have of the whole may be what we please, by the portion of the beam that we notch down. If the wall plate lie duly before the heel of the rafter, there is no risk of straining the tie across or breaking it, because the thrust is made direct to that point where the beam is supported. The action is the same as against the joggle on the head or foot of a king post. We have no doubt but that this is a very effectual joint. It is not, however, much practised. It is said that the sloping seam at the shoulder lodges water; but the great reason seems to be a secret notion that it weakens the tie-beam. If we consider the direction in which it acts as a tie, we must acknowledge that this form takes the best method for bringing the whole of it into action.

Fig. 32. exhibits a form that is more general, but certainly worse. What part of the thrust that is not borne by the tenon acts obliquely on the point of the shoulder, and gives the whole a tendency to rise up and slide outward.

The shoulder joint is sometimes formed like the dotted line *a b c d e f g* of fig. 32. This is much more agreeable to the true principle, and would be a very perfect method, were it not that the intervals *b d* and *d f* are so short that the little wooden triangles *b c d*, *d e f*, will be easily pushed off their bases *b d*, *d f*.

Fig. 33. seems to have the most general approbation. It is the joint recommended by Price (page 7.), and copied into all books of carpentry as the *true joint* for a rafter foot. The visible shoulder-joint is flush with the upper surface of the tie-beam. The angle of the tenon at the tie nearly bisects the obtuse angle formed by the rafter and the beam, and is therefore somewhat oblique to the thrust. The inner shoulder *a c* is nearly perpendicular to *b d*. The lower angle of the tenon is cut off horizontally as at *e d*. Fig 34. is a section of the beam and rafter foot, shewing the different shoulders.

We do not perceive the peculiar merit of this joint. The effect of the three oblique abutments *a b*, *a c*, *e d*, is undoubtedly to make the whole bear on the outer end of the mortise, and there is no other part of the tie-beam that makes immediate resistance. Its only advantage over a tenon extending in the direction of the thrust is, that it will not tear up the wood above it. Had the inner shoulder had the form *e c i*, having its face *i c* perpendicular, it would certainly have acted more powerfully in stretching many filaments of the tie-beam, and would have had much less tendency to force out the end of the mortise. The little bit *c i* would have prevented the sliding upwards along *e c*. At any rate, the joint *a b* being flush with the beam, prevents any sensible abutment on the shoulder *a c*.

Fig. 33. N° 2. is a simpler, and in our opinion a preferable joint. We observe it practised by the most eminent carpenters for all oblique thrusts; but it surely employs less of the cohesion of the tie-beam than might be used without weakening it, at least when it is supported on the other side by the wall plate.

Fig. 33. N° 3. is also much practised by the first carpenters.

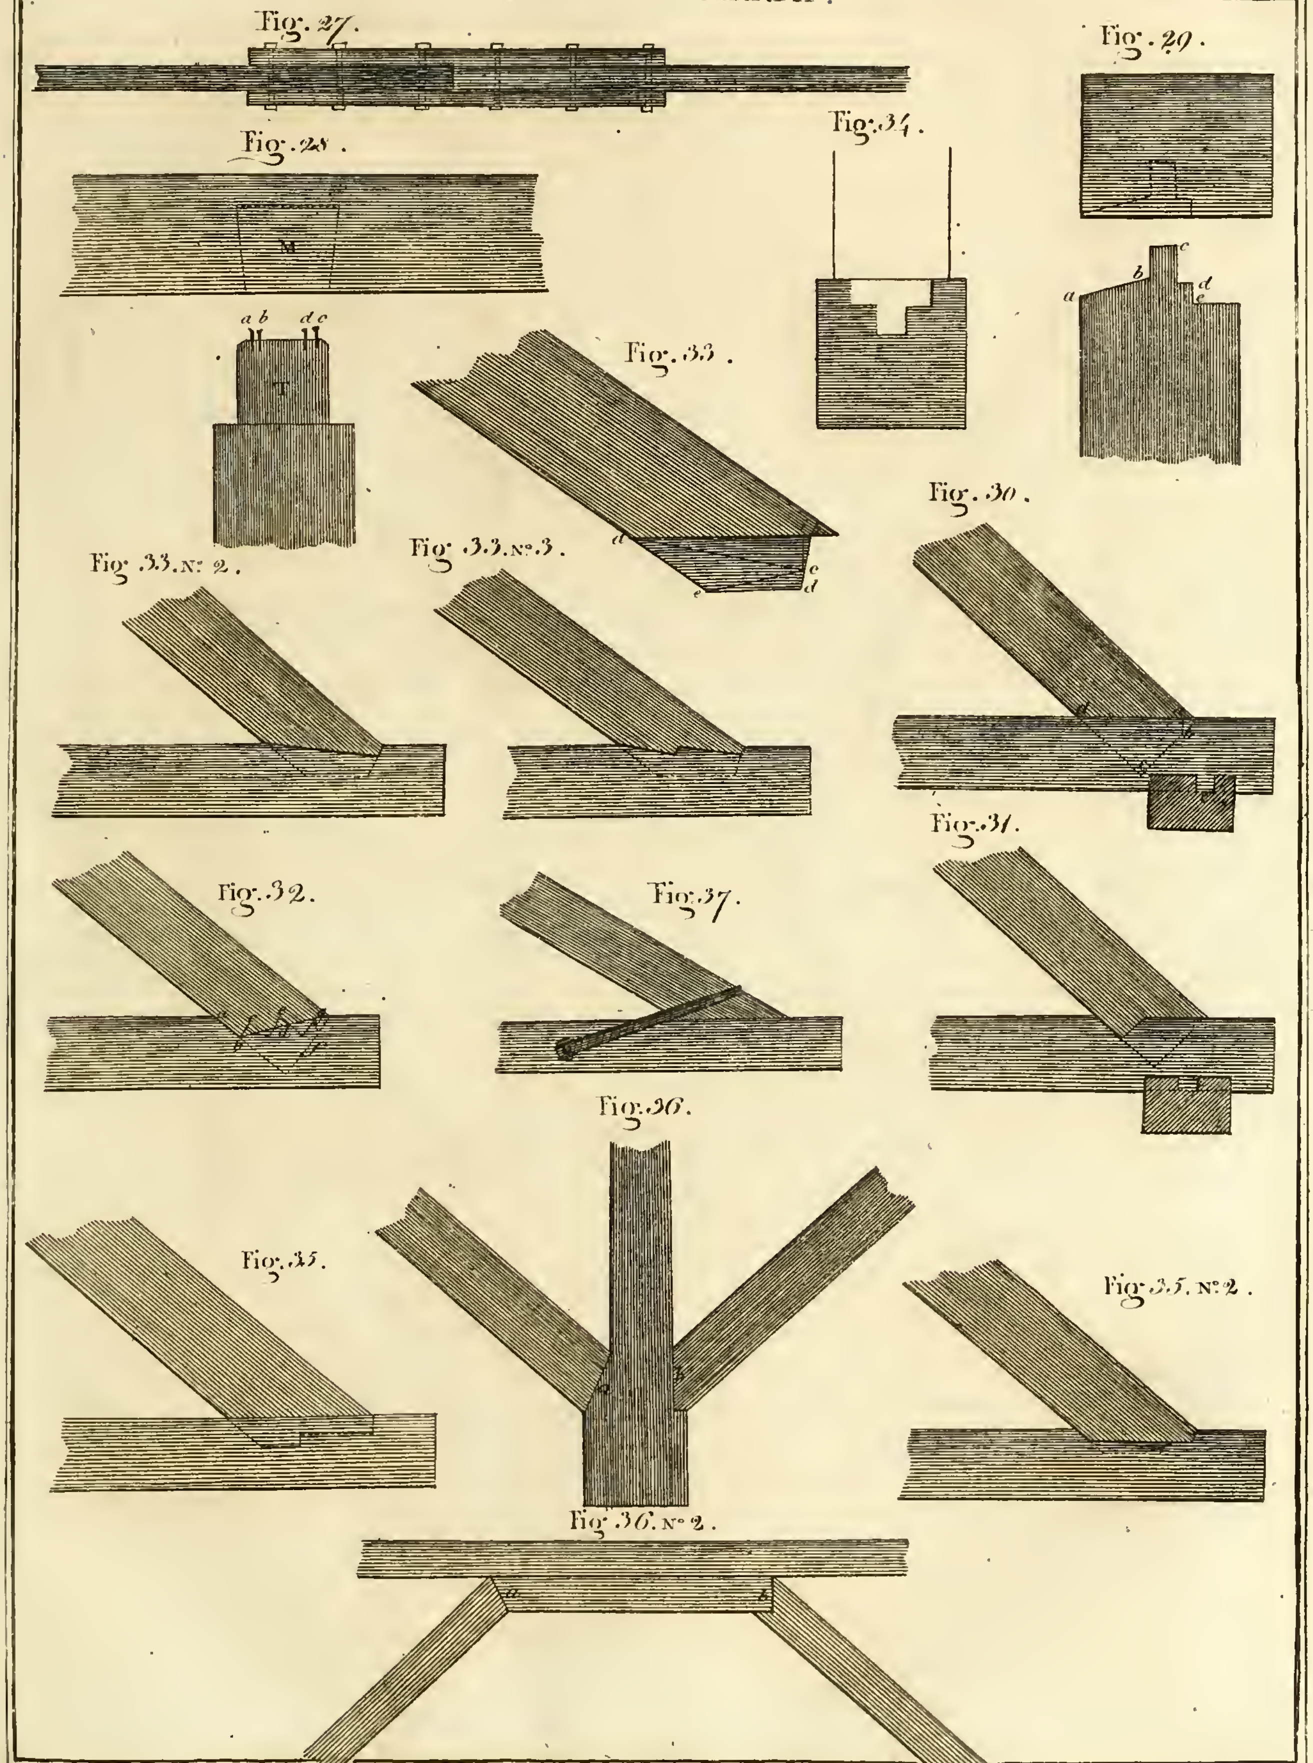
Fig. 35. is proposed by Mr Nicholson (page 65.) as preferable to fig. 33. n° 3. because the abutment of the inner part is better supported. This is certainly the case; but it supposes the whole rafter to go to the bottom of the socket, and the beam to be thicker than the rafter. Some may think that this will weaken the beam too much, when it is no broader than the rafter is thick; in which case they think that it requires a deeper socket than Nicholson has given it. Perhaps the advantages of Nicholson's construction may be had by a joint like fig. 35. n° 2.

Whatever is the form of these butting joints, great care should be taken that all parts bear alike, and the artist will attend to the magnitude of the different surfaces. In the general compression, the greater surfaces will be less compressed, and the smaller will therefore change most. When all has settled, every part should be *equally* close. Because great logs are moved with difficulty, it is very troublesome to try the joint frequently to see how the parts fit; therefore we must expect less accuracy in the interior parts. This should make us prefer those joints whose efficacy depends chiefly on the visible joint. 39 Circumstances to be attended to.

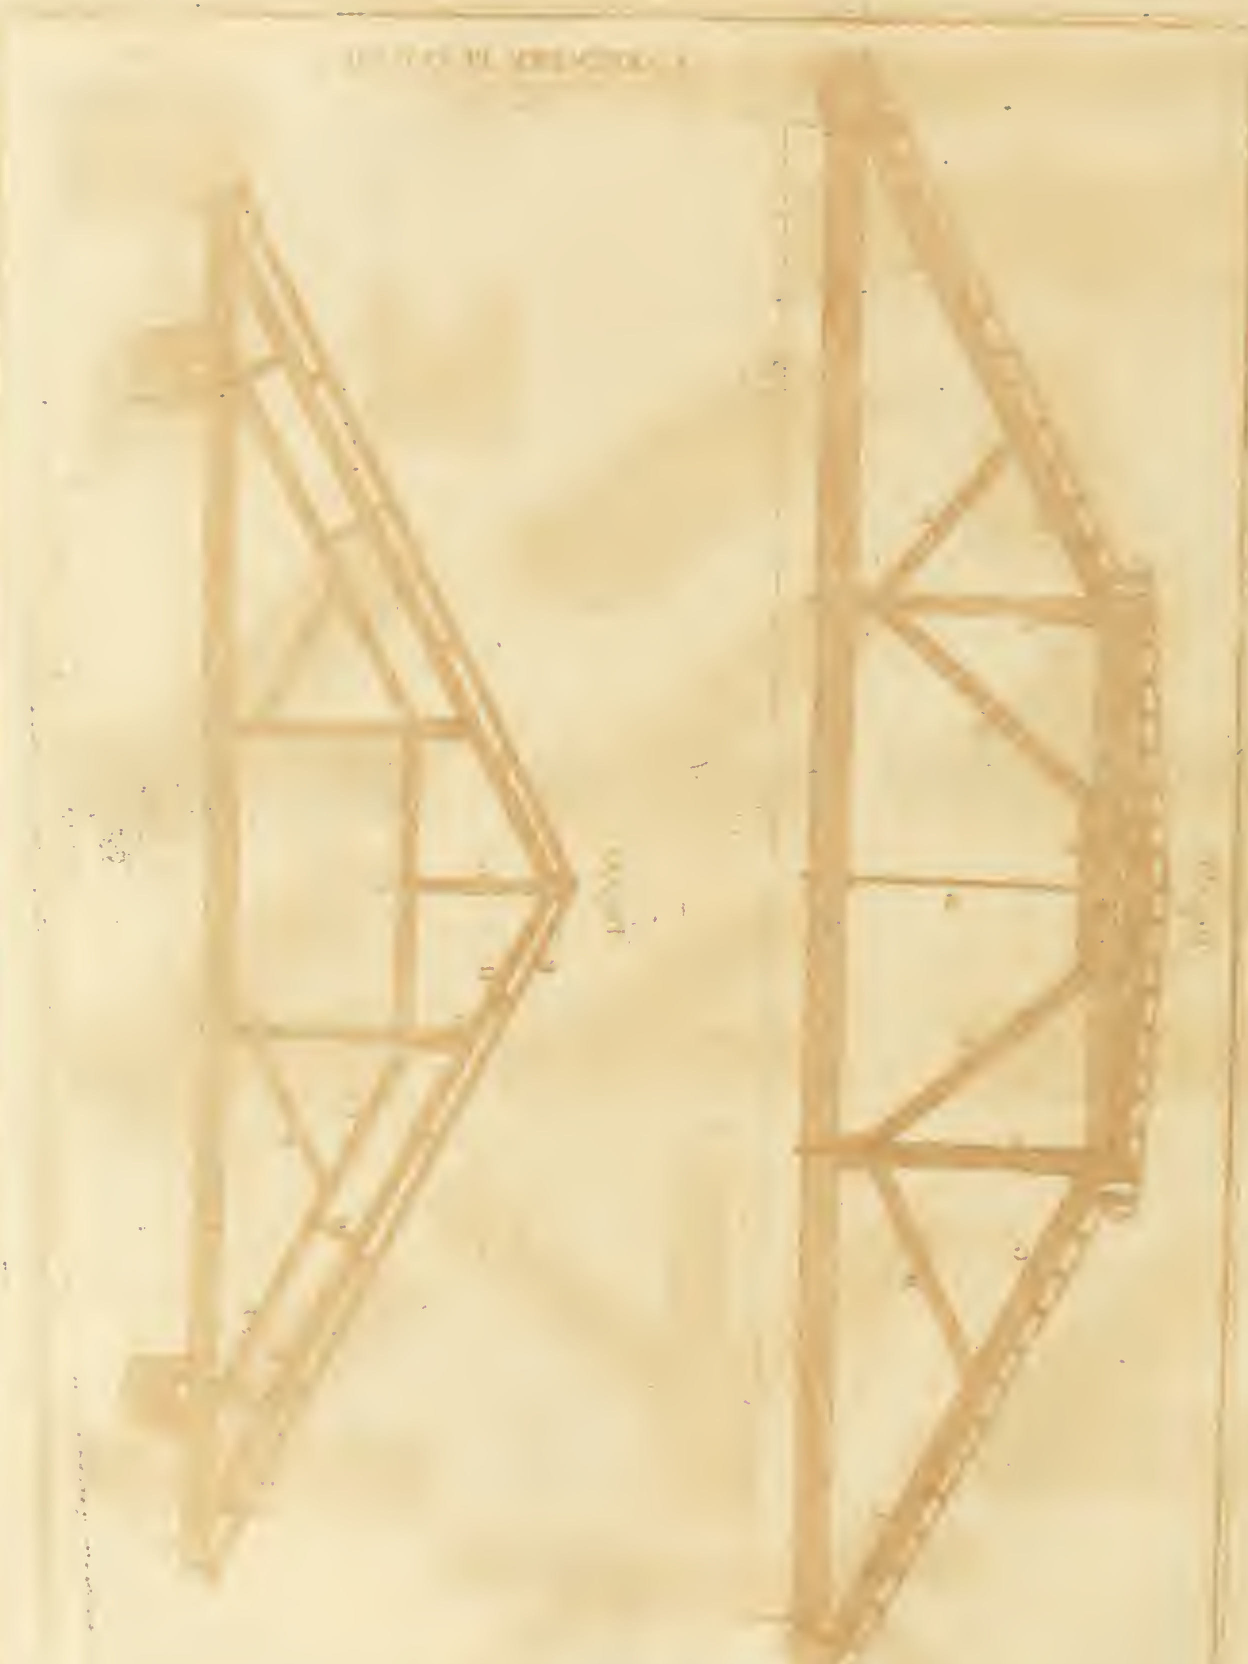
It appears from all that we have said on this subject, that a very small part of the cohesion of the tie-beam is sufficient for withstanding the horizontal thrust of a roof, even though very low pitched. If therefore no other use is made of the tie-beam, one much slenderer may be used, and blocks may be firmly fixed to the ends, on which the rafters might abut, as they do on the joggles on the head and foot of a king post. Although a tie-beam has commonly floors or ceilings to carry, and sometimes the workshops and store rooms of a theatre, and therefore requires a great scantling, yet there frequently occur in machines and engines very oblique stretchers, which have no other office, and are generally made of dimensions quite inadequate to their situation, often containing ten times the necessary quantity of timber. It is therefore of importance to ascertain the most perfect manner of executing such a joint. We have directed the attention to the principles that are really concerned in the effect. In all hazardous cases, the carpenter calls in the assistance of iron straps; and they are frequently necessary, even in roofs, notwithstanding this superabundant strength of the tie-beam. But this is generally owing to bad construction of the wooden joint, or to the failure of it by time. Straps will be considered in their place.

There needs but little to be said of the joints at a joggle worked out of solid timber; they are not near so difficult as the last. When the size of a log will allow the joggle to receive the whole breadth of the abutting brace, it ought certainly to be made with a square shoulder; or, which is still better, an arch of a circle, having the other end of the brace for its centre. Indeed this in general will not sensibly differ from a straight line perpendicular to the brace. By this circular form, the settling of the roof makes no change in the abutment; but when there is not sufficient stuff for this,

CARPENTRY PLATE. XI.



HWW. sc.



CARPENTRY PLATE XII.

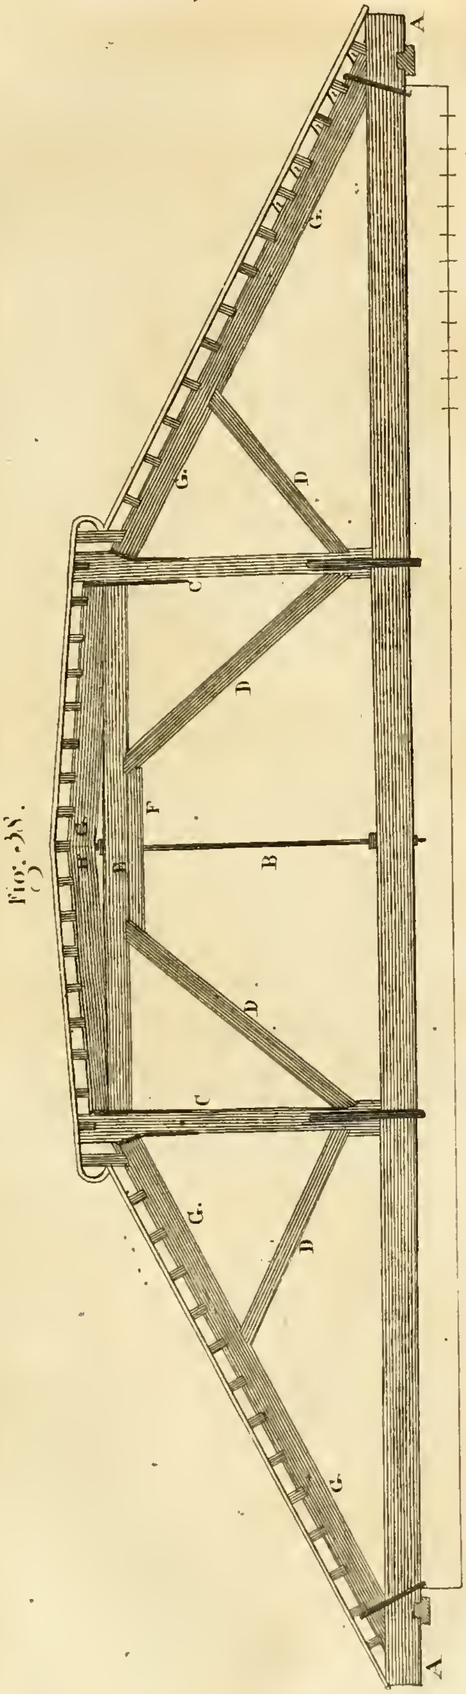


Fig. 38.

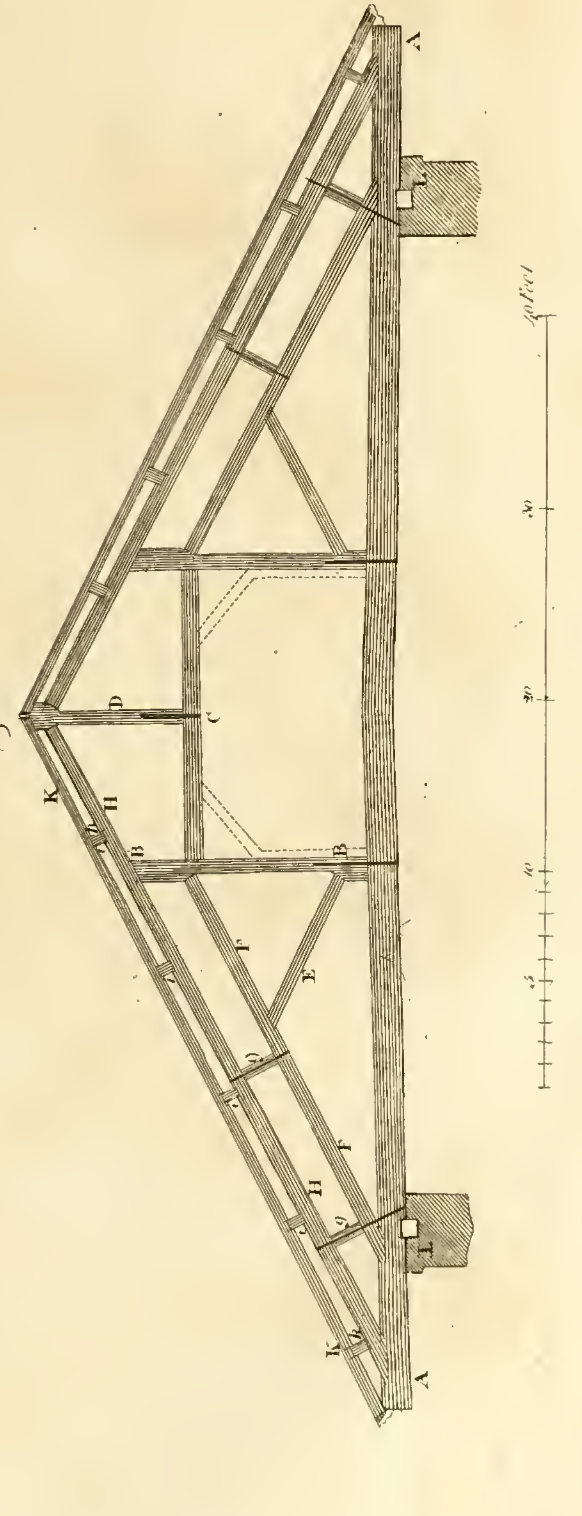

Fig. 39.

this, we muſt avoid bevel joints at the ſhoulders, becauſe theſe always tend to make the brace ſlide off. The brace in fig. 36. muſt not be joined as at *a*, but as at *b*, or ſome equivalent manner. Obſerve the joints at the head of the main poſts of Drury Lane theatre, fig. D.

40 Butting joints. When the very oblique action of one ſide of a frame of carpentry does not extend but compreſs the piece on which it abuts (as in fig. 11.), there is no difficulty in the joint. Indeed a joining is unneceſſary, and it is enough that the pieces abut on each other; and we have only to take care that the mutual preſſure be equally borne by all parts, and that it do not produce lateral preſſures, which may cauſe one of the pieces to ſlide on the butting joint. A very ſlight mortiſe and tenon is ſufficient at the joggle of a king poſt with a rafter or ſtraining beam. It is beſt, in general, to make the butting plain, biſecting the angle formed by the ſides, or elſe perpendicular to one of the pieces. In fig. 36. n° 2. where the ſtraining beam *a b* cannot ſlip away from the preſſure, the joint *a* is preferable to *b*, or indeed to any uneven joint, which never fails to produce very unequal preſſures on the different parts, by which ſome are crippled, others are ſplintered off, &c.

41 Directions for placing iron ſtraps. When it is neceſſary to employ iron ſtraps for ſtrengthening a joint, a conſiderable attention is neceſſary, that we may place them properly. The firſt thing to be determined is the direction of the ſtrain. This is learned by the obſervations in the beginning of this article. We muſt then reſolve this ſtrain into a ſtrain parallel to each piece, and another perpendicular to it. Then the ſtrap which is to be made faſt to any of the pieces muſt be ſo fixed, that it ſhall reſiſt in the direction parallel to the piece. Frequently this cannot be done; but we muſt come as near to it as we can. In ſuch caſes we muſt ſuppoſe that the aſſemblage yields a little to the preſſures which act on it. We muſt examine what change of ſhape a ſmall yielding will produce. We muſt now ſee how this will affect the iron ſtrap which we have already ſuppoſed attached to the joint in ſome manner that we thought ſuitable. This ſettling will perhaps draw the pieces away from it, leaving it looſe and unſerviceable (this frequently happens to the plates which are put to ſecure the obtuſe angles of butting timbers, when their bolts are at ſome diſtance from the angles, eſpecially when theſe plates are laid on the inſide of the angles); or it may cauſe it to compreſs the pieces harder than before; in which caſe it is anſwering our intention. But it may be producing croſs ſtrains, which may break them; or it may be crippling them. We can hardly give any general rules; but the reader will do well to read what is written in n° 36. and 41. of the article Roof, *Encycl.* In n° 36. he will ſee the nature of the ſtrap or ſtirrup, by which the king poſt carries the tie-beam. The ſtrap that we obſerve moſt generally ill-placed is that which connects the foot of the rafter with the beam. It only binds down the rafter, but does not act againſt its horizontal thruſt. It ſhould be placed farther back on the beam, with a bolt through it, which will allow it to turn round. It ſhould embrace the rafter almoſt horizontally near the foot, and ſhould be notched ſquare with the back of the rafter. Such a conſtruction is repreſented in fig. 37. By moving round the eye-bolt, it follows the rafter, and cannot pinch and cripple it, which it always does in its ordinary form. We are of opinion that ſtraps which have eye-bolts in the very angles, and allow all motion round them, are of all the moſt perfect. A branched ſtrap, ſuch as may at once bind the king poſt and the two braces which butt on its foot, will be more ſerviceable if it have a joint. When a roof warps, thoſe branched ſtraps frequently break the tenons, by affording a fulcrum in one of their bolts. An attentive and judicious artiſt will conſider how the beams will act on ſuch occaſions, and will avoid giving riſe to theſe great ſtrains by levers—A ſkilful carpenter never employs many ſtraps, conſidering them as auxiliaries foreign to his art, and ſubject to imperfections in workmanſhip which he cannot diſcern nor amend. We muſt refer the reader to Nicholſon's Carpenter and Joiner's Assistant for a more particular account of the various forms of ſtirrups, ſcrewed rods, and other iron work for carrying tie-beams, &c.

As for thoſe that are neceſſary for the turning joints of great engines conſtructed of timber, they make no part of the art of carpentry.

42 Examples of different pieces of carpentry. After having attempted to give a ſyſtematic view of the principles of framing carpentry, we ſhall conclude, by giving ſome examples which will illuſtrate and confirm the foregoing principles.

43 Roof of Greenwich chapel. Fig. 38. is the roof of the chapel of the Royal Hoſpital at Greenwich, conſtructed by Mr S. Wyatt.

	Inches Scantling.
AA, is the tie-beam, 57 feet long, ſpanning 51 feet clear	14 by 12
CC, Queen poſts	9 × 12
D, Braces	9 × 7
E, Truſs beam,	10 × 7
F, Straining piece	6 × 7
G, Principal rafters	10 × 7
H, A cambered beam for the platform	9.7
B, An iron ſtring, ſupporting the tie-beam	2 × 2

The truſſes are 7 feet apart, and the whole is covered with lead, the boarding being ſupported by horizontal ledgers *h*, *h*, of 6 by 4 inches.

This is a beautiful roof, and contains leſs timber than moſt of its dimenſions. The parts are all diſpoſed with great judgment. Perhaps the iron rod is unneceſſary; but it adds great ſtiffneſs to the whole.

The iron ſtraps at the rafter feet would have had more effect if not ſo oblique. Thoſe at the head of the poſts are very effective.

We may obſerve, however, that the joints between the ſtraining beam and its braces are not of the beſt kind, and tend to bruiſe both the ſtraining beam and the truſs beam above it.

44 St Pauls, Covent Garden. Fig. 39. the roof of St Paul's, Covent Garden, conſtructed by Mr Wapſhot in 1796.

AA, Tie-beam ſpanning 50 feet 2 inches	16.12
B, Queen poſt	9 × 8
C, Truſs beam	10 × 8
D, King poſt (14 at the joggle)	9 × 8
E, Brace	8 × 7½
FF, Principal brace (at bottom)	10 × 8½
HH, Principal rafter (at bottom)	10 × 8½
gg, Studs ſupporting the rafter	8 × 8

This roof far excels the original one put up by Inigo Jones. One of its truſſes contains 198 feet of timber.

One

One of the old roof had 273, but had many inactive timbers, and others ill difpofed (*N. B.* The figure which we gave of it in the article Roof, copied from Price, is very erroneous). The internal trufs FCF is admirably contrived for fupporting the exterior rafters, without any preffure on the far projecting ends of the tie-beam. The former roof had bent them greatly, fo as to appear ungraceful.

We think that the camber (fix inches) of the tie-beam is rather hurtful; becaufe by fettling, the beam lengthens; and this muft be accompanied by a *confiderable* finking of the roof. This will appear by calculation.

45 Birmingham theatre. Fig. 40. the roof of Birmingham theatre, conftructed by Mr Geo. Saunders. The fpan is 80 feet clear, and the truffes are 10 feet apart.

A, Is an oak corbel	9 × 5
B, Inner plate	9 × 9
C, Wall plate	8 × 5½
D, Pole plate	7 × 5
E, Beam	15 × 15
F, Straining beam	12 × 9
G, Oak king poft (in the fhaft)	9 × 9
H, Oak queen poft (in the fhaft)	7 × 9
I, Principal rafters	9 × 9½
K, Common ditto	4 × 2½
L, Principal braces	9 and 6 × 9
M, Common ditto	6 × 9
N, Purlins	7 × 5
Q, Straining fill	5½ × 9

This roof is a fine fpecimen of Britifh carpentry, and is one of the boldeft and lighteft roofs in Europe. The ftraining fill Q gives a firm abutment to the principal braces, and the fpace between the pofts is 19½ feet wide, affording roomy workfhops for the carpenters and other workmen connected with a theatre. The contrivance for taking double hold of the wall, which is very thin, is excellent. There is alfo added a beam (marked R), bolted down to the tie-beams. The intention of this was to prevent the total failure of fo bold a truffing, if any of the tie-beams fhould fail at the end by rot.

46 Drury Lane theatre. Akin to this roof is fig. 41. the roof of Drury Lane theatre, 80 feet 3 inches in the clear, and the truffes 15 feet apart, conftructed by Mr Edward Grey Saunders.

A, Beams	10 by 7
B, Rafters	7 × 7
C, King pofts	12 × 7
D, Struts	5 × 7
E, Purlins	9 × 5
G, Pole plates	5 × 5
I, Common rafters	5 × 4
K, Tie-beam to the main trufs	15 × 12
L, Pofts to ditto	15 × 12
M, Principal braces to ditto	14 and 12 × 12
N, Struts	8 × 12
P, Straining beams	12 × 12

The main beams are truffed in the middle fpace with oak truffes 5 inches fquare. This was neceffary for its width of 32 feet, occupied by the carpenters, painters, &c. The great fpace between the truffes afford good ftore-rooms, dreffing rooms, &c.

It is probable that this roof has not its equal in the world for lightnefs, ftiffnefs, and ftrength. The main trufs is fo judicioufly framed, that each of them will fafely bear a load of near 300 tons; fo it is not likely that they will ever be quarter loaded. The divifion of the whole into three parts makes the exterior roofings very light. The ftrains are admirably kept from the walls, and the walls are even firmly bound together by the roof. They alfo take off the dead weight from the main trufs one-third.

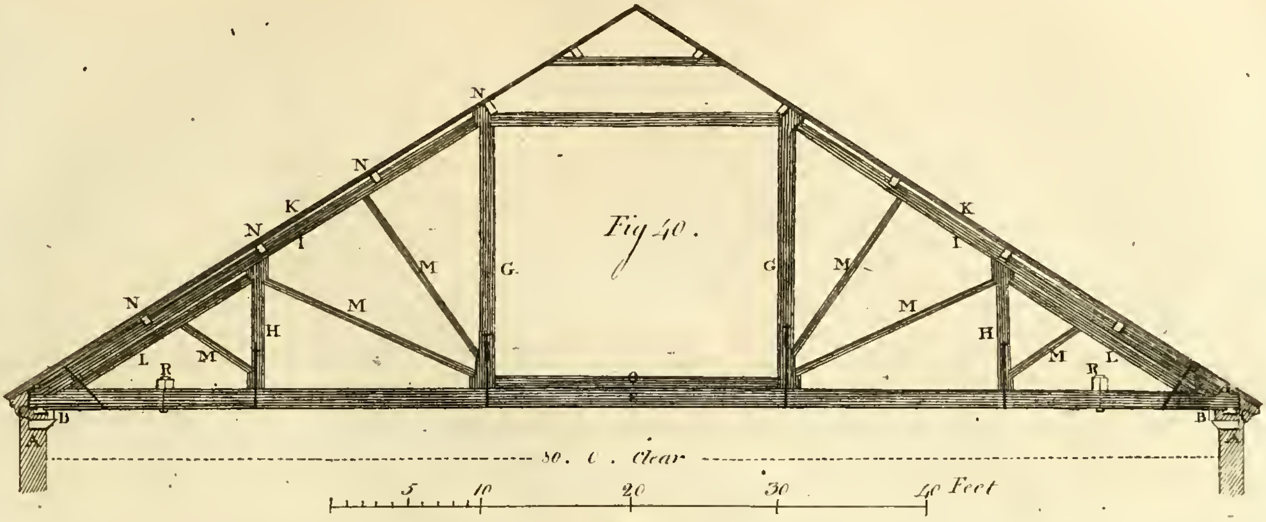
The intelligent reader will perceive that all thefe roofs are on one principle, depending on a trufs of three pieces and a ftraight tie-beam. This is indeed the great principle of a trufs, and is a ftep beyond the roof with two rafters and a king poft. It admits of much greater variety of forms, and of greater extent. We may fee, that even the middle part may be carried to any fpace, and yet be flat at top; for the trufs-beam may be fupported in the middle by an inverted king poft (of timber, not iron), carried by iron or wooden ties from its extremities: And the fame ties may carry the horizontal tie-beam K; for till K be torn afunder, or M, M, and P be crippled, nothing can fail. 47 Remarks.

The roof of St Martin's church in the Fields is conftructed on good principles, and every piece properly difpofed. But although its fpan does not exceed 40 feet from column to column, it contains more timber in a trufs than there is in one of Drury Lane theatre. The roof of the chapel at Greenwich, that of St Paul's, Covent Garden, that of Birmingham, and that of Drury Lane theatres, form a feries gradually more perfect. Such fpecimens afford excellent leffons to the artifts. We therefore account them a ufeful prefent to the public.

48 Project by Mr Nicholfon. There is a very ingenious project offered to the public by Mr Nicholfon (Carpenter's Affiftant, p. 68.) He propofes iron rods for king pofts, queen pofts, and all other fituations where beams perform the office of ties. This is in profecution of the notions which we publifhed in the article Roof of the *Encycl.* (fee n° 36, 37.) He receives the feet of the braces and ftruts in a focket very well connected with the foot of his iron king poft; and he fecures the feet of his queen pofts from being pufhed inwards, by interpofing a ftraining fill. He does not even mortife the foot of his principal rafter into the end of the tie-beam, but fets it in a focket like a fhoe, at the end of an iron bar, which is bolted into the tie-beam a good way back. All the parts are formed and difpofed with the precifion of a perfon thoroughly acquainted with the fubject; and we have not the fmalleft doubt of the fuccefs of the project, and the complete fecurity and durability of his roofs, and we expect to fee many of them executed. We abound in iron, but we muft fend abroad for building timber. This is therefore a valuable project; at the fame time, however, let us not over-rate its value. Iron is but about 12 times ftronger than red fir, and is more than 12 times heavier; nor is it cheaper, weight for weight, or ftrength for ftrength.

Our illuftrations and examples have been chiefly taken from roofs, becaufe they are the moft familiar inftances of the difficult problems of the art. We could have wifhed for more room even on this fubject. The conftruction of dome roofs has been (we think) miftaken, and the difficulty is much lefs than is imagined. We mean in refpect of ftrength; for we grant that the obliquity

CARPENTRY PLATE. XIII.



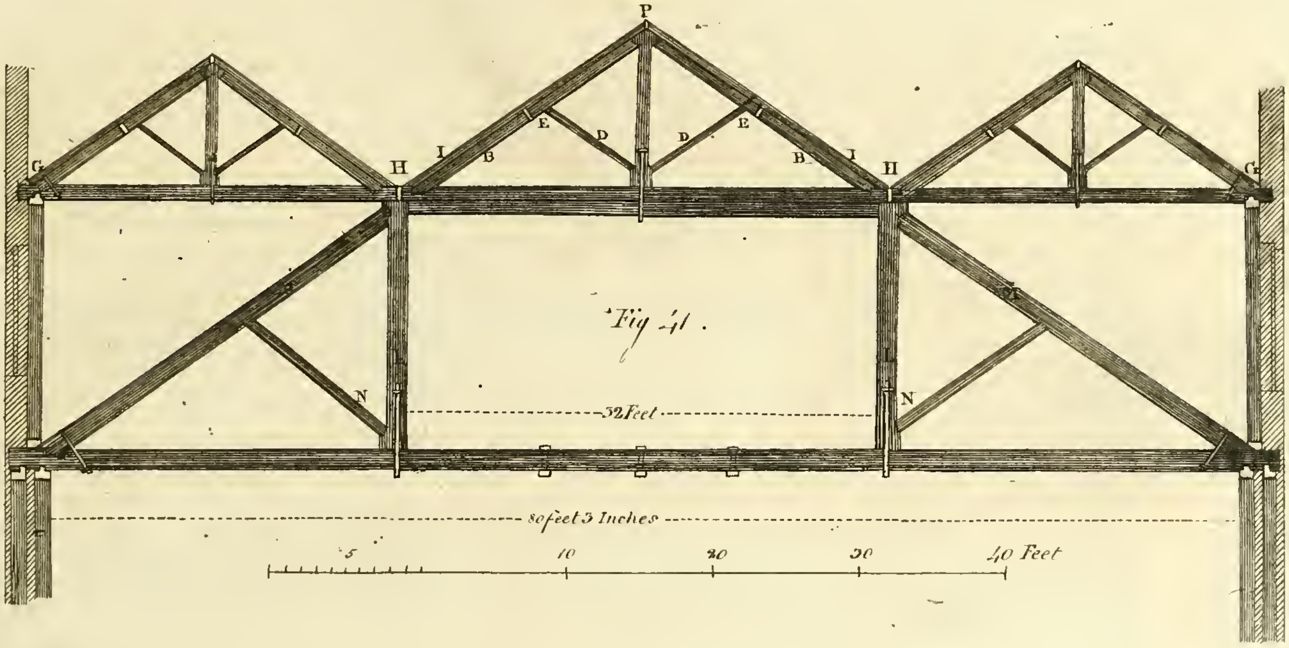


Fig 42.

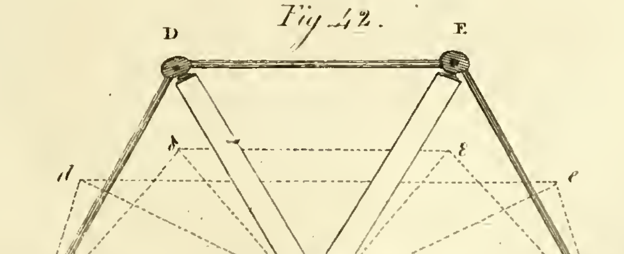

H.B.W.fc.

obliquity of the joints, and a general intricacy, increaſes the trouble of workmanſhip exceedingly. Another opportunity may perhaps occur for conſidering this ſubject.

49 Wooden bridges. Wooden bridges form another claſs equally difficult and important; but our limits are already overpaſſed, and will not admit them. The principle on which they ſhould all be conſtructed, without exception, is that of a truſs, avoiding all lateral bearings on any of the timbers. In the application of this principle, we muſt farther remark, that the angles of our truſs ſhould be as acute as poſſible; therefore we ſhould make it of as few and as long pieces as we can, taking care to prevent the bending of the truſs beams by bridles, which embrace them, but without preſſing them to either ſide. When the truſs conſiſts of many pieces, the angles are very obtuſe; and the thruſts increaſe nearly in the duplicate proportion of the number of angles. The proper maxims will readily occur to the artiſt who conſiders with attention the ſpecimens of centres or coombs, which we ſhall give in the article CENTRE.

50 Framing of great levers. With reſpect to the frames of carpentry which occur in engines and great machines, the varieties are ſuch that it would require a volume to treat of them properly. The principles are already laid down; and if the reader be really intereſted in the ſtudy, he will engage in it with ſeriouſneſs, and cannot fail of being inſtructed. We recommend to his conſideration, as a ſpecimen of what may be done in this way, the working beam of Hornblower's ſteam engine (ſee *STEAM-Engine*, n° 84. *Encycl.*) When the beam muſt act by chains hung from the upper end of arch heads, the framing there given ſeems very ſcientifically conſtructed; at the ſame time, we think that a ſtrap of wrought iron, reaching the whole length of the upper bar (ſee the figure), would be vaſtly preferable to thoſe partial plates which the engineer has put there, for the bolts will ſoon work looſe.

But when arches are not neceſſary, the form employed by Mr Watt is vaſtly preferable, both for ſimplicity and for ſtrength. It conſiſts of a ſimple beam AB (fig. 42.), having the gudgeon C on the upper ſide. The two piſton rods are attached to wrought iron joints A and B. Two ſtrong ſtruts DC, EC reſt on the upper ſide of the gudgeon, and carry an iron ſtring ADEB, conſiſting of three pieces, connected with the ſtruts by proper joints of wrought iron. A more minute deſcription is not needed for a clear conception of the principle. No part of this is expoſed to a croſs ſtrain; even the beam AB might be ſawed through at the middle. The iron ſtring is the only part which is ſtretched; for AC, DC, EC, BC, are all in a ſtate of compreſſion. We have made the angles equal, that all may be as great as poſſible, and the preſſure on the ſtruts and ſtrings a minimum. Mr Watt makes them much lower, as $A\,d\,e\,B$, or $A\,\delta\,\epsilon\,B$. But this is for economy, becauſe the ſtrength is almoſt inſuperable. It might be made with wooden ſtrings; but the workmanſhip of the joints would more than compenſate the cheapneſs of the materials.

WE offer this article to the public with deference, and we hope for an indulgent reception of our eſſay on a ſubject which is in a manner new, and would require much ſtudy. We have beſtowed our chief attention on the ſtrength of the conſtruction, becauſe it is here that perſons of the profeſſion have the moſt ſcanty information. We beg them not to conſider our obſervations as too refined, and that they will ſtudy them with care. One principle runs through the whole; and when that is clearly conceived and familiar to the mind, we venture to ſay that the practitioner will find it of eaſy application, and that he will improve every performance by a continual reference to it. 51 Concluſion.

If this attempt to inſtruct our moſt valuable and much eſteemed artiſts ſhall appear to meet with their approbation, it may encourage us to engage in the ſerious taſk of compoſing a ſyſtem on the ſubject. But this is a great work, and will require much time and liberal contribution of knowledge from the eminent carpenters who do honour to this country by their works.

CAR

CAR

Carré. CARRE' (Lewis), was, in 1663, born in the province of Brie in France; and refuſing to enter into the ſervice of the church, for which his education was intended to fit him, he incurred the diſpleaſure of his father. His reſources being thus cut off, he was obliged to quit the univerſity, and go out into the world without employment or the means of ſubſiſtence. In this exigency he was ſomehow introduced to the celebrated Malebranche, and retained by him as an amanuenſis. Under this great maſter he ſtudied mathematics and metaphyſics, and could hardly fail to become ſtrongly attached to the latter ſcience. After reſiding ſeven years with Malebranche, he reſolved to enter upon ſome employment, which might procure him a leſs precarious eſtabliſhment than what could be enjoyed by the favour of any individual: and with that view he began at Paris a courſe of lectures in mathematics, metaphyſics, and moral philoſophy, to ſuch young ladies and gentlemen as choſe to put themſelves under his tuition. When we think of the maſter under whom he himſelf ſtudied thoſe ſciences, we cannot wonder that he made geometry ſerve merely as an introduction to his beloved metaphyſics; and indeed the order of his courſe deſerves to be univerſally adopted. It is ſurely much better to accuſtom the youthful mind to ſteady apprehenſion and patient thinking in the ſtudy of the ancient geometry, before it proceed to ſciences more abſtract, than to hurry it at once, as is the practice in ſome univerſities, into all the mazes and intricacies of what is called the firſt philoſophy. Carré.

But although M. Carré gave the preference to metaphyſics, he did not neglect mathematics; and while he taught both, he took care to make himſelf acquainted with all the new diſcoveries in the latter. This was all that his conſtant attendance on his pupils would allow him to do till the year 1697, when M. Varignon ſo remarkable for his extreme ſcrupulouſneſs in the choice of his eleves, took M. Carré to him in that ſtation. Soon after, viz. in the year 1700, our author, thinking himſelf bound to do ſomething that might render him worthy of that title, publiſhed the firſt complete work on the integral calculus, under the title of "A Method of

Carré.

of Measuring Surfaces and Solids, and finding their Centres of Gravity, Percussion, and Oscillation." He afterwards discovered some errors in the work, and was candid enough to own and correct them in a subsequent edition.

In a little time M. Carré became associate, and at length one of the pensioners of the Academy. And as this was a sufficient establishment for one who knew so well how to keep his desires within just bounds, he gave himself up entirely to study; and as he enjoyed the appointment of mechanician, he applied himself more particularly to mechanics. He took also a survey of every branch relating to music; such as the doctrine of sounds, and the description of musical instruments; though he despised the practice of music as a mere sensual pleasure. Some sketches of his ingenuity and industry in this way may be seen in the Memoirs of the French Academy of Sciences. M. Carré also composed some treatises on other branches of natural philosophy, and some on mathematical subjects; all which he bequeathed to that illustrious body, though it does not appear that any of them have yet been published. It is not unlikely that he was hindered from putting the last hand to them by a train of disorders proceeding from a bad digestion, which, after harrassing him during the space of five or six years, at length brought him to the grave in 1711, at 48 years of age.

Though he possessed a considerable degree of science and much ingenuity, like many other eminent men he had neglected in his youth to study the language of his native country. In consequence of this, one of the earliest of his female pupils, perceiving that his language was the reverse of elegant, told him pleasantly, that as an acknowledgment for the trouble which he had taken to teach her philosophy, she would in return teach him French; and he ever afterwards said, that from her lessons he had reaped great advantage. To this circumstance probably it was owing that he thought more highly of the genius of women than that of men.

The following is a chronological list of his memoirs printed in the volumes of the Academy.

1. The rectification of curve lines by tangents, 1701. 2. Solution of a problem proposed to geometricians, &c. 1701. 3. Reflections on the table of equations, 1701. 4. On the cause of the refraction of light, 1702. 5. Why the tides are always augmenting from Brest to St Malo, and diminishing along the coasts of Normandy, 1702. 6. The number and the names of musical instruments, 1702. 7. On the vinegar which causes small stones to roll upon an inclined plane, 1703. 8. On the rectification, &c. of the caustics by reflection, 1703. 9. Method for the rectification of curves, 1704. 10. Observations on the production of sound, 1704. 11. On a curve formed from a circle, 1705. 12. On the refraction of musket-balls in water, and on the resistance of that fluid, 1705. 13. Experiments on capillary tubes, 1705. 14. On the proportion of pipes to have a determinate quantity of water, 1705. 15. On the laws of motion, 1706. 16. On the properties of pendulums, with some new properties of the parabola, 1707. 17. On the proportion of cylinders, that their sounds may form the musical cords, 1709. 18. On the elasticity of the air, 1710. 19. On catoptrics, 1710. 20. On the Monochord: in the *Machines*, tom. 1. with some other pieces, not mathematical.

Carteret ‖ Cassini.

CARTERET, a maritime co. of Newbern district, N. Carolina, on Core and Pamlico Sounds. It contains 3732 inhabitants, including 713 slaves. Beaufort is the chief town.—*Morse.*

CASCABEL, the knob or button of metal behind the breech of a cannon, as a kind of handle by which to elevate and direct the piece; to which some add the fillet and ogees as far as the base-ring.

CASCO *Bay*, in the district of Maine, spreads N. W. between Cape Elizabeth on the S. W. and Cape Small Point on the N. E. Within these points, which are about 40 miles apart, are about 300 small islands, some of which are inhabited, and nearly all more or less cultivated. The land on these islands, and on the opposite coast on the main, is the best for agriculture of any on the sea coast of this country. Casco includes several bays. *Maquoit Bay* lies about 20 miles N. of Cape Elizabeth. The waters of Casco extend several arms or creeks of salt water into the country. The waters go up *Meadows River*, where vessels of a considerable size are carried by the tide, and where it flows within one mile of the waters of Kennebeck. On the E. side of Cape Elizabeth is the arm of the sea called *Stroudwater*. Farther E. is *Presumpscot River* formerly called Presumpca, or Presumpkeag, which rises in Sebago Pond. This river opens to the waters of Casco Bay on the E. of Portland; its extent is not great, but it has several valuable mills upon it. *Rayal's River* called by the natives Westecustego, falls into the bay 6 miles from Presumpscot River. It has a good harbor at its mouth for small vessels; and has several mills upon it; 2 miles higher a fall obstructs the navigation. Between it and Kennebeck there are no rivers; some creeks and harbors of Casco Bay throw themselves into the main land, affording harbors for small vessels, and intersecting the country in various forms.—*Morse.*

CASEMATE, or CAZEMATE, in fortification, a kind of vault or arch of stone-work, in that part of the flank of a bastion next the curtain; serving as a battery to defend the face of the opposite bastion, and the moat or ditch.

It is now seldom used, because the batteries of the enemy are apt to bury the artillery of the casemate in the ruins of the vault; beside, the great smoke made by the discharge of the cannon renders it intolerable to the men. So that, instead of the ancient covered casemates, later engineers have contrived open ones, only guarded by a parapet, &c.

CASEMATE is also used for a well with several subterraneous branches, dug in the passage of the bastion, till the miner is heard at work, and air given to the mine.

CASSINI (James), a celebrated French astronomer, was born at Paris February 18. 1677, being the younger son of Johannes Dominicus Cassini, of whom some account has been given in the *Encyclopædia*.

After his first studies in his father's house, in which it is not to be supposed that mathematics and astronomy would be neglected, he was sent to study philosophy at the Mazarine college, where the celebrated Varignon was then professor of mathematics. From the assistance of this eminent man young Cassini profited so well, that at 15 years of age he supported a mathematical thesis with great honour. At the age of 17 he was admitted a member of the Academy of Sciences; and the same year he accompanied

accompanied his father in a journey to Italy, where he affifted him in the verification of the meridian at Bologna and other meafurements. On his return he performed fimilar operations in a journey into Holland, where he difcovered fome errors in the meafure of the earth by Snell, the refult of which was communicated to the Academy in 1702. He made alfo a vifit to England in 1696, where he was made a member of the Royal Society. In 1712 he fucceeded his father as aftronomer royal at the obfervatory of Paris. In 1717 he gave to the Academy his refearches on the diftance of the fixed ftars; in which he fhewed that the whole annual orbit, of near 200 millions of miles diameter, is but as a point in comparifon of that diftance. The fame year he communicated alfo his difcoveries concerning the inclination of the orbits of the fatellites in general, and efpecially of thofe of Saturn's fatellites and ring. In 1725 he undertook to determine the caufe of the moon's libration, by which fhe fhews fometimes a little towards one fide, and fometimes a little on the other, of that half which is commonly behind or hid from our view.

In 1732 an important queftion in aftronomy exercifed the ingenuity of our author. His father had determined, by his obfervations, that the planet Venus revolved about her axis in the fpace of 23 hours; and M. Bianchini had publifhed a work in 1729, in which he fettled the period of the fame revolution at 24 days 8 hours. From an examination of Bianchini's obfervations which were upon the fpots in Venus, he difcovered that he had intermitted his obfervations for the fpace of three hours, from which caufe he had probably miftaken new fpots for the old ones, and fo had been led into the miftake. The probability is, that both had fallen into fome miftake, or that they had proceeded on very different principles; for otherwife fuch different refults are wholly unaccountable. Dr Herfchel feems fatisfied that the period of the revolution is lefs than Bianchini has made; but he does not fay what it is, or that it is not much greater than it was fuppofed by Caffini. Our author, after he had convicted Bianchini, as he thought, of error, determined the nature and quantity of the acceleration of the motion of Jupiter at half a fecond per year, and of that of the retardation of Saturn at two minutes per year; that thefe quantities would go on increafing for 2000 years, and then would decreafe again. In 1740 he publifhed his Aftronomical Tables, and his Elements of Aftronomy; very extenfive and accurate works.

Although aftronomy was the principal object of our author's confideration, he did not confine himfelf abfolutely to that branch, but made occafional excurfions into other fields. We owe alfo to him, for example, Experiments on Electricity, or the Light produced by Bodies by Friction; Experiments on the Recoil of Fire-arms; Refearches on the Rife of the Mercury in the Barometer at different Heights above the Level of the Sea; Reflections on the perfecting of Burning-glaffes; and other Memoirs.

The French Academy had properly judged, that one of its moft important objects was the meafurement of the earth. In 1669 Picard meafured a little more than a degree of latitude to the north of Paris; but as that extent appeared too fmall from which to conclude the whole circumference with fufficient accuracy, it was refolved to continue that meafurement on the meridian of Paris to the north and the fouth, through the whole extent of the country. Accordingly, in 1683, the late M. de la Hire continued that on the north fide of Paris, and the older Caffini that on the fouth fide. The latter was affifted in 1700 in the continuation of this operation by his fon our author. The fame work was farther continued by the fame academicians; and, finally, the part left unfinifhed by De la Hire in the north was finifhed in 1718 by our author, with the late Maraldi, and De la Hire the younger.

Thefe operations produced a confiderable degree of precifion. It appeared alfo, from this meafured extent of fix degrees, that the degrees were of different lengths in different parts of the meridian; and in fuch fort that our author concluded, in the volume publifhed for 1718, that they decreafed more and more towards the pole, and that therefore the figure of the earth was that of an oblong fpheroid, or having its axis longer than the equatorial diameter. He alfo meafured the perpendicular to the fame meridian, and compared the meafured diftance with the differences of longitude as before determined by the eclipfes of Jupiter's fatellites: whence he concluded that the length of the degrees of longitude was fmaller than it would be on a fphere, and that therefore again the figure of the earth was an oblong fpheroid, contrary to the determination of Newton by the theory of gravity. Though Newton was of all men the moft averfe from controverfy, the other mathematicians in Britain did not tamely fubmit to conclufions in direct oppofition to the fundamental doctrine of a philofopher of whofe talents the nation was juftly proud. The confequence was, that the French government fent two different fets of meafurers, the one to meafure a degree at the equator, the other at the polar circle; and the comparifon of the whole determined the figure to be an oblate fpheroid, contrary to Caffini's determination.

After a long and laborious life, James Caffini died in April 1756, in confequence of a fall, and was fucceeded in the Academy and Obfervatory by the fubject of the following article. He publifhed, A Treatife on the Magnitude and Figure of the Earth; as alfo, The Elements or Theory of the Planets, with Tables; befide an infinite number of papers in the Memoirs of the Academy, from the year 1699 to 1755.

Cassini de Thury (Cefar François), a celebrated French aftronomer, director of the obfervatory, penfioner aftronomer, and member of moft of the learned focieties of Europe, was born at Paris June 17. 1714, being the fecond fon of James Caffini, the fubject of the preceding memoir, whofe occupations and talents he inherited and fupported with great honour. He received his firft leffons in aftronomy and mathematics from MM. Maraldi and Camus; and made fuch a rapid progrefs, that when he was not more than ten years of age he calculated the phafes of a total eclipfe of the fun. At the age of eighteen he accompanied his father in his two journeys undertaken for drawing the perpendicular to the obfervatory meridian from Strafbourg to Breft. From that time a general chart of France was devifed; for which purpofe it was neceffary to traverfe the country by feveral lines parallel and perpendicular to the meridian of Paris, and our author was charged with the conduct of this bufinefs; in which he was fo fcrupulous as to meafure again what had been meafured ed by his father. This great work was publifhed in 1740, with a chart fhewing the new meridian of Paris, by two different feries of triangles, paffing along the fea coafts to Bayonne, traverfing the frontiers of Spain to the Mediterranean and Antibes, and thence along the eaftern limits of France to Dunkirk, with parallel and perpendicular lines defcribed at the diftance of 6000 toifes from one another, from fide to fide of the country.

A tour which, in 1741, our author made in Flanders, in the train of the king, gave rife, at his majefty's inftance, to the chart of France; relative to which Caffini publifhed different works, as well as a great number of the fheets of the chart itfelf. In 1761 he undertook an expedition into Germany, for the purpofe of continuing to Vienna the perpendicular of the Paris meridian; to unite the triangles of the chart of France with the points taken in Germany; to prepare the means of extending into that country the fame plan as in France; and thus to eftablifh fucceffively for all Europe a moft ufeful uniformity.—Our author was at Vienna the 6th of June 1761, the day of the tranfit of the planet Venus over the fun, of which he obferved as much as the ftate of the weather would permit him to do, and publifhed the account of it in his *Voyage en Allemagne*.

Finally, M. Caffini, always meditating the perfection of his grand defign, profited of the peace of 1783 to propofe the joining of certain points taken upon the Englifh coaft with thofe which had been determined on the coaft of France, and thus to connect the general chart of the latter with that of the Britifh ifles, like as he had before united it with thofe of Flanders and Germany. The propofal was favourably received by the Englifh government, and prefently carried into effect under the direction of the Royal Society, the execution being committed to the late General Roy. See the life of that general in this *Supplement*.

Between the years 1735 and 1770, M. Caffini publifhed, in the volumes of Memoirs of the French Academy, a prodigious number of pieces, confifting chiefly of aftronomical obfervations and queftions; among which are obfervable, refearches concerning the parallax of the fun, the Moon, Mars, and Venus; on aftronomical refractions, and the effect caufed in their quantity and laws by the weather; numerous obfervations on the obliquity of the ecliptic, and on the law of its variations. In fhort, he cultivated aftronomy for fifty years, the moft important for that fcience that ever elapfed for the magnitude and variety of objects, in which he commonly fuftained a principal fhare.

M. Caffini was of a very ftrong and vigorous conftitution, which carried him through the many laborious operations in geography and aftronomy which he conducted. An habitual retention of urine, however, rendered the laft twelve years of his life very painful and diftreffing, till it was at length terminated by the fmallpox the 4th of September 1784, in the 71ft year of his age. He was fucceeded in the academy, and as director of the obfervatory, by his only fon John-Dominic Caffini, the fourth in order of direct defcent who has filled that honourable ftation.

CASTINE, the fhire town of Hancock co. diftrict of Maine, is fituated on Penobfcot bay. It was taken from the town of Penobfcot, and incorporated in Feb. 1796. It is named after a French gentleman who refided here 130 years ago, as alfo

Castine *River*, which is about 14 miles long, is navigable for 6 miles, and has feveral mills at the head of it. It empties into Penobfcot bay.—*Morse*.

CASTLETON, a townfhip and river in Rutland co. Vermont, 20 miles S. E. of Mount Independence, at Ticonderoga. Lake Bombazon is chiefly in this town and fends its waters into Caftleton River which, rifing in Pittsford, paffes through this town in a S. wefterly courfe, and falls into Pultney River in the town of Fairhaven, a little below Col. Lyon's iron works. Fort Warner ftands in this town. Inhabitants 805.—*ib.*

CASTRAMETATION, the art or act of encamping an army.

CASWELL *Co.* in Hillfborough diftrict, N. Carolina, borders on Virginia N. It contains 10,096 inhabitants, of whom 2,736 are flaves. Leefburg is the chief town.—*Morse*.

CATABAW *Indians*, a fmall tribe who have one town called Catabaw, fituated on the river of that name, N. lat. 34. 49. on the boundary line between N. and S. Carolina, and contains about 450 inhabitants, of which about 150 are fighting men. They are the only tribe which refides in the ftate: 144 000 acres of land were granted them by the proprietary government. Thefe are the remains of a formidable nation, the braveft and moft generous enemy the fix nations had; but they have degenerated fince they have been furrounded by the whites. —*ib.*

CATACAUSTICS, or Catacaustic Curves, in the higher geometry, are the fpecies of cauftic curves formed by reflection.

CATACOUSTICS, or Cataphonics, is the fcience of reflected founds; or that part of acouftics which treats of the properties of echoes.

CATALOGUES of Books, is a fubject of which a very curious hiftory has been given to the world by Profeffor Beckmann. In the Encyclopædia mention has been made of fome of the moft valuable catalogues, their defects pointed out, and rules given for making them more perfect; but nothing has there been faid of their origin, or of the ufes which might be made of the oldeft catalogues.

According to the Profeffor, George Willer, whom fome improperly call Viller, and others Walter, a bookfeller at Augfburg, who kept a very large fhop, and frequented the Franckfort fairs, firft fell upon the plan of caufing to be printed, before every fair, a catalogue of all the new books, in which the fize and printers names were marked Le Mire, better known under the name of Miræus, fays, that catalogues were firft printed in the year 1554; but Labbe (A), Reimann (B) and Heumann (C), who took their information from Le Mire, make the year erroneoufly to be 1564.

Willer's

(C) Confpectus Reip. Litter. c. vi. § 2. p. 316.

Catalogues.

Willer's catalogues were printed till the year 1592 by Nicol. Baſſæus, printer at Franckfort. Other bookſellers, however, muſt have ſoon publiſhed catalogues of the like kind, though that of Willer continued a long time to be the principal.

In all theſe catalogues, which are in quarto and not paged, the following order is obſerved. The Latin books occupy the firſt place, beginning with the Proteſtant theological works, perhaps becauſe Willer was a Lutheran; then come the Catholic; and after theſe, books of juriſprudence, medicine, philoſophy, poetry, and muſic. The ſecond place is aſſigned to German books, which are arranged in the ſame manner.

The bookſellers of Leipſic ſoon perceived the advantage of catalogues, and began not only to reprint thoſe of Franckfort, but alſo to enlarge them with many books which had not been brought to the fairs in that city. Our author had for ſome time in his cuſtody, *Catalogus univerſalis pro nundinis Francofurtenſibus vernalibus, de anno* 1600; or, A catalogue of all the books on ſale in Book-ſtreet, Franckfort, and alſo of the books publiſhed at Leipſic, which have not been brought to Franckfort, with the permiſſion of his highneſs the elector of Saxony, to thoſe new works which have appeared at Leipſic. Printed at Leipſic by Abraham Lamberg, and to be had at his ſhop. On the September catalogue of the ſame year, it is ſaid that it is printed from the Franckfort copy with additions. He found an Imperial privilege for the firſt time on the Franckfort September catalogue of 1616: *Cum gratia et privilegio ſpeciali ſ. caeſ. maj. Proſtat. apud J. Krugerum Auguſtanum.*

Reimmann ſays, that after Willer's death the catalogue was publiſhed by the Leipſic bookſeller Henning Groſſe, and by his ſon and grandſon. The council of Franckfort cauſed ſeveral regulations to be iſſued reſpecting catalogues; an account of which may be ſeen in D. Orth's *Treatiſe on the Imperial Fairs at Franckfort.* After the buſineſs of book-ſelling was drawn from Franckfort to Leipſic, occaſioned principally by the reſtrictions to which it was ſubjected at the former by the cenſors, no more catalogues were printed there; and the ſhops in Book-ſtreet were gradually converted into taverns (A).

"In the 16th century there were few libraries; and theſe, which did not contain many books, were in monaſteries, and conſiſted principally of theological, philoſophical, and hiſtorical works, with a few, however, on juriſprudence and medicine; while thoſe which treated of agriculture, manufactures, and trade, were thought unworthy of the notice of the learned, or of being preſerved in large collections. The number of theſe works was, nevertheleſs, far from being inconſiderable; and at any rate, many of them would have been of great uſe, as they would have ſerved to illuſtrate the inſtructive hiſtory of the arts. Catalogues which might have given occaſion to inquiries after books, that may be ſtill ſomewhere preſerved, have ſuffered the fate of tombſtones, which, being waſted and crumbled to pieces by the deſtroying hand of time, become no longer legible. A complete ſeries of them perhaps is nowhere to be found, at leaſt I do not remember (ſays the Profeſſor) to have ever ſeen one in any library."

Catalogues ‖ Catalogue of the Stars.

This loſs, however, he thinks, might be in ſome meaſure ſupplied by the catalogues of Cleſs and Draudius; who, by the deſire of ſome bookſellers, collected together all the catalogues which had been publiſhed at the different fairs in different years. The work of Cleſs has the following title: *Unius ſæculi ejuſque virorum litteratorum monumentis tum florentiſſimi, tum fertiliſſimi, ab anno* 1500 *ad* 1602 *nundinarum autumnalium incluſive, elenchus conſummatiſſimus—deſumtus partim ex ſingularum nundinarum catalogis, partim ex bibliothecis.* Auctore Joanne Cleſſio, Winecceuſi, Hannoio, philoſopho ac medico.—By the editor's preface, it appears that the firſt edition was publiſhed in 1592. The order is almoſt the ſame as that obſerved by Willer in his catalogues.

The work of Draudius, which was printed in ſeveral quarto volumes for the firſt time in 1611, and afterwards in 1625, is far larger, more complete, and more methodical. Our author, however, confeſſes, that he never ſaw a perfect copy of either edition. This catalogue conſiſts of three parts; of which the firſt has the title of *Bibliotheca claſſica, ſive Catalogus officinalis, in quo ſinguli ſingularum facultatum ac profeſſionum libri, qui in quavis fere lingua extant—recenſentur; uſque ad annum* 1624 *incluſive.* Auctore M. Georgio Draudio.—It contains Latin works on theology, juriſprudence, medicine, hiſtory, geography, and politics. The copy in the library of the univerſity of Gottingen ends at page 1304, which has, however, a catch-word, that ſeems to indicate a deficiency.—The ſecond part is entitled, *Bibliotheca claſſica ſive Catalogus officinalis, in quo philoſophici artiumque adeo humaniorum, poetici etiam et muſici libri uſque ad annum* 1624 *continentur.* This part, containing Latin books alſo, begins at page 1298, and ends with page 1654, which is followed by an index of all the authors mentioned.—A ſmaller volume, of 302 pages, without an index, has for title, *Bibliotheca exotica, ſive Catalogus officinalis librorum peregrinis linguis uſualibus ſcriptorum.* And a third part, forming 759 pages, beſides an index of the authors, is called, *Bibliotheca librorum Germanicorum claſſica;* that is, A catalogue of all the books printed in the German language till the year 1625.

We have reaſon to believe that there are other editions of this catalogue than thoſe mentioned by Profeſſor Beckman; and it might become ſome prince or great man, for it is not a work for a bookſeller, to compare all the editions together, and publiſh a new one more correct than any that is at preſent extant. This indeed would be an expenſive and not an eaſy taſk; for our author obſerves, that all the oldeſt catalogues had the ſame faults as thoſe of later date, and that theſe faults have been copied by Draudius. Many books are mentioned which were never printed, and many titles, names, and dates, are given incorrectly; but Draudius nevertheleſs is well worth the attention of any one who may be inclined to employ his time and ingenuity on the hiſtory of literature; and his work certainly was of uſe to Haller when he compoſed his *Bibliotheca.*

CATALOGUES *of the Stars,* have uſually been diſpoſed, either

(A) Joh. Adolp. Stock, Frankfurter Chronik, p. 77.

either as collected into certain figures called *conſtellations*, or according to their right aſcenſions, that is, the order of their paſſing over the meridian.

Of the principal catalogues, according to the firſt of theſe forms, an account has been given in the *Encyclopædia*. The firſt catalogue, we believe, that was printed in the new or ſecond form, according to the order of the right aſcenſions, is that of De la Caille, given in his Ephemerides for the ten years between 1755 and 1765, and printed in 1755. It contains the right aſcenſions and declinations of 307 ſtars, adapted to the beginning of the year 1750. In 1757 De la Caille publiſhed his *Aſtronomiæ Fundamenta*, containing a catalogue of the right aſcenſions and declinations of 398 ſtars, likewiſe adapted to the beginning of 1750. And in 1763, the year after his death, was publiſhed the *Cœlum Auſtrale Stelliferum* of the ſame author; containing a catalogue of the places of 1942 ſtars, all ſituated to the ſouthward of the tropic of Capricorn, and obſerved by him while he was at the Cape of Good Hope in 1751 and 1752; their places being alſo adapted to the beginning of 1750. In the ſame year was publiſhed his Ephemerides for the ten years between 1765 and 1775; in the introduction to which are given the places of 515 zodiacal ſtars, all deduced from the obſervations of the ſame author; the places adapted to the beginning of the year 1765.

In the Nautical Almanac for 1773, is given a catalogue of 387 ſtars, in right aſcenſion, declination, longitude, and latitude, derived from the obſervations of the late celebrated Dr Bradley, and adjuſted to the beginning of the year 1760. This ſmall catalogue, and the reſults of about 1200 obſervations of the moon, are all that the public have yet ſeen of the multiplied labours of this moſt accurate and indefatigable obſerver, although he has now (1798) been dead upwards of 36 years.

In 1775 was publiſhed a thin volume, intitled, *Opera Inedita*, containing ſeveral papers of the late Tobias Mayer, and among them a catalogue of the right aſcenſions and declinations of 998 ſtars, which may be occulted by the moon and planets; the places being adapted to the beginning of the year 1756.

At the end of the firſt volume of "Aſtronomical Obſervations made at the Royal Obſervatory at Greenwich," publiſhed in 1776, Dr Maſkelyne, the preſent aſtronomer royal, has given a catalogue of the places of 34 principal ſtars, in right aſcenſion and north polar diſtance, adapted to the beginning of the year 1770.

Theſe being the reſult of ſeveral years repeated obſervations, made with the utmoſt care, and the beſt inſtruments, it may be preſumed are exceedingly accurate.

In 1782, M. Bode of Berlin publiſhed a very extenſive catalogue of 5058 of the fixed ſtars, collected from the obſervations of Flamſteed, Bradley, Hevelius, Mayer, De la Caille, Meſſier, Monnier, D'Arquier, and other aſtronomers; all adapted to the beginning of the year 1780; and accompanied with a celeſtial atlas or ſet of maps of the conſtellations, engraved in a moſt delicate and beautiful manner.

To theſe may be added Dr Herſchel's catalogue of double ſtars printed in the Phil. Tranſ. for 1782 and 1783; Meſſier's nebulæ and cluſters of ſtars, publiſhed in the *Connoiſſance des Temps* for 1784; and Herſchel's catalogue of the ſame kind, given in the Phil. Tranſ. for 1786.

In 1789 Mr Francis Wollaſton publiſhed "A Specimen of a General Aſtronomical Catalogue, in Zones of North-polar Diſtance, and adapted to January 1. 1790." Theſe ſtars are collected from all the catalogues before-mentioned, from that of Hevelius downwards. This work contains five diſtinct catalogues; viz. Dr Maſkelyne's new catalogue of 36 principal ſtars; a general catalogue of all the ſtars, in zones of north-polar diſtance; an index to the general catalogue; a catalogue of all the ſtars, in the order in which they paſs the meridian; and a catalogue of zodiacal ſtars, in longitude and latitude.

Finally, in 1792, Dr Zach publiſhed at Gotha, *Tabulæ Motuum Solis*; to which is annexed a new catalogue of the principal fixed ſtars, from his own obſervations made in the years 1787, 1788, 1789, 1790. This catalogue contains the right aſcenſions and declinations of 381 principal ſtars, adapted to the beginning of the year 1800.—*Hutton's Mathematical Dictionary.*

Beſides theſe two methods of forming *catalogues* of the ſtars, Dr Herſchel has conceived a new one, in which the comparative brightneſs of the ſtars is accurately expreſſed. It is long ſince aſtronomers were firſt led to arrange the ſtars in claſſes of different magnitudes by their various degrees of brilliancy or luſtre. Brightneſs and ſize have at all times been conſidered as ſynonymous terms; ſo that the brighteſt ſtars have been referred to the claſs comprehending thoſe of the firſt magnitude; and as the ſubſequent orders of ſtars have been ſuppoſed to decreaſe in luſtre, their magnitude has been determined in the ſame decreaſing progreſſion: but the want of ſome fixed and ſatisfactory ſtandard of luſtre has been the ſource of conſiderable confuſion and uncertainty in ſettling the relative magnitudes of the ſtars. A ſtar marked 1. 2m. is ſuppoſed to be between the firſt and ſecond magnitude; but 2. 1m. intimates, that the ſtar is nearly of the ſecond magnitude, and that it partakes ſomewhat of the luſtre of a ſtar of the firſt order. Such ſubdiviſions may be of ſome uſe in aſcertaining ſtars of the firſt, ſecond, and third claſſes; but the expreſſions 5m, 5.6m, 6.5m, 6m, muſt be very vague and indefinite. Dr Herſchel obſerves that he has found them ſo in fact; and he therefore conſiders this method of pointing out the different luſtre of ſtars as a reference to an imaginary ſtandard. If any dependence could be placed on this method of magnitudes, "it would follow, that no leſs than eleven ſtars in the conſtellation of the Lion, namely, $\beta\ \sigma\ \pi\ \xi$ A *b c d* 54. 48, 72, had all undergone a change in their luſtre ſince Flamſteed's time: For if the idea of magnitudes had been a clear one, our author, who marked β 1.2m. and γ 2m. ought to be underſtood to mean that β is larger than γ; but we now find that actually γ is larger than β. Every one of the eleven ſtars (ſays Dr Herſchel) which I have pointed out may be reduced to the ſame contradiction."

The author has pointed out the inſtances of the inſufficiency of this method, and of the uncertain concluſions that are deduced from it in determining the comparative brightneſs of ſtars found not only in Mr Flamſteed's catalogue, but alſo in the catalogues of other aſtronomers. It is ſufficiently apparent that the preſent method of expreſſing the brightneſs of the ſtars is very defective.

Catalogue of the Stars. defective. Dr Herſchel therefore propoſes a different mode, that is more preciſe and ſatisfactory.

"I place each ſtar (he ſays), inſtead of giving its magnitude, into a ſhort ſeries, conſtructed upon the order of brightneſs of the neareſt proper ſtars. For inſtance, to expreſs the luſtre of D, I ſay CDE. By this ſhort notation, inſtead of referring the ſtar D to an imaginary uncertain ſtandard, I refer it to a preciſe and determined exiſting one. C is a ſtar that has a greater luſtre than D, and E is another of leſs brightneſs than D. Both C and E are neighbouring ſtars, choſen in ſuch a manner that I may ſee them at the ſame time with D, and therefore may be able to compare them properly. The luſtre of C is in the ſame manner aſcertained by BCD; that of B by ABC; and alſo the brightneſs of E by DEF; and that of F by EFG.

"That this is the moſt natural, as well as the moſt effectual way to expreſs the brightneſs of a ſtar, and by that means to detect any change that may happen in its luſtre, will appear, when we conſider what is requiſite to aſcertain ſuch a change. We can certainly not wiſh for a more deciſive evidence, than to be aſſured, by actual inſpection, that a certain ſtar is now no longer more or leſs bright than ſuch other ſtars to which it has been formerly compared; provided we are at the ſame time aſſured that thoſe other ſtars remain ſtill in their former unaltered luſtre. But if the ſtar D will no longer ſtand in its former order CDE, it muſt have undergone a change; and if that order is now to be expreſſed by CED, the ſtar has loſt ſome part of its luſtre; if, on the contrary, it ought now to be denoted by DCE, its brightneſs muſt have had ſome addition. Then, if we ſhould doubt the ſtability of C and E, we have recourſe to the orders BCD and DEF, which expreſs their luſtre; or even to ABC and EFG, which continue the ſeries both ways. Now having before us the ſeries BCDEF, or if neceſſary even the more extended one ABCDEFG, it will be impoſſible to miſtake a change of brightneſs in D, when every member of the ſeries is found in its proper order except D."

In the author's journal or catalogue, in which the order of the luſtre of the ſtars is fixed, each ſtar bears its own proper name or number, *e g.* "the brightneſs of the ſtar δ Leonis may be expreſſed by β δ ε Leonis, or better by 94—68—17 Leonis; theſe being the numbers which the three above ſtars bear in the Britiſh catalogue of fixed ſtars."

This method of arrangement occurred to Dr Herſchel ſo early as the year 1782; but he was diverted from the regular purſuit of it by a variety of other aſtronomical engagements. After many trials, he propoſed, in the Tranſactions of the Royal Society of London for 1796, the plan which appeared to him the moſt eligible. It is as follows:—Inſtead of denoting particular ſtars by letters, he makes uſe of numbers; and in his choice of the ſtars which are to expreſs the luſtre of any particular one, he directs his firſt view to perfect equality. When two ſtars ſeem to be ſimilar both in brightneſs and magnitude, he puts down their numbers together, ſeparated merely by a point, as 30.24 Leonis; but if two ſtars, which at firſt ſeemed alike in their luſtre, appeared on a longer inſpection to be different, and the preference ſhould be always decidedly in favour of the ſame ſtar, he ſeparates theſe ſtars by a comma, thus, 41,94 Leonis. This order muſt not be varied; nor can three ſuch ſtars, as 20, 40, 39, Libræ, admit of a different arrangement. If the ſtate of the heavens ſhould be ſuch as to require a different order in theſe numbers, we may certainly infer that a change has taken place in the luſtre of one or more of them. When two ſtars differ very little in brightneſs, but ſo that the preference of the one to the other is indiſputable, the numbers that expreſs them are ſeparated by a ſhort line as 17—70 Leonis, or 68—17—70 Leonis. When two ſtars differ ſo much in brightneſs, that one or two other ſtars might be interpoſed between them, and ſtill leave ſufficient room for diſtinction, they are diſtinguiſhed by a line and comma, thus, —, or by two lines, as 32— —41 Leonis. A greater difference than this is denoted by a broken line, thus — — — 29 Bootis. On the whole, the author obſerves, the marks and diſtinctions which he has adopted cannot poſſibly be miſtaken; "a point denoting equality of luſtre; a comma indicating the leaſt perceptible difference; a ſhort line to mark a decided but ſmall ſuperiority; a line and comma, or double line, to expreſs a conſiderable and ſtriking exceſs of brightneſs; and a broken line to mark any other ſuperiority which is to be looked upon as of no uſe in eſtimations that are intended for the purpoſe of directing changes."

The difficulties that attend this arrangement are not diſguiſed; but the importance and utility of it more than compenſate for the labour which it muſt neceſſarily require. By a method of this kind, many diſcoveries of changeable and periodical ſtars might probably have been made, which have eſcaped the moſt diligent and accurate obſervers. We might then, as the author ſuggeſts, be enabled to reſolve a problem in which we are all immediately concerned.

"Who, for inſtance, would not wiſh to know what degree of permanency we ought to aſcribe to the luſtre of our ſun? Not only the ſtability of our climates, but the very exiſtence of the whole animal and vegetable creation itſelf, is involved in the queſtion. Where can we hope to receive information upon this ſubject but from aſtronomical obſervations? If it be allowed to admit the ſimilarity of ſtars with our ſun as a point eſtabliſhed, how neceſſary will it be to take notice of the ſate of our neighbouring *ſuns*, in order to gueſs at that of our own! That *ſtar*, which among the multitude we have dignified by the name of *ſun*, to-morrow may ſlowly begin to undergo a gradual decay of brightneſs, like β Leonis, α Ceti, α Draconis, δ Urſæ majoris, and many other diminiſhing ſtars that will be mentioned in my catalogues. It may ſuddenly increaſe, like the wonderful ſtar in the back of Caſſiopea's chair, and the no leſs remarkable one in the foot of Serpentarius; or gradually come on like β Geminorum, β Ceti, ζ Sagittarii, and many other increaſing ſtars, for which I alſo refer to my catalogues; and, laſtly, it may turn into a periodical one of 25 days duration, as Algol is one of three days, δ Cephei of five, β Lyræ of ſix, η Antinoi of ſeven days, and as many others as are of various periods."

Having thus explained the general principle on which this catalogue is formed, as we find it in the author's firſt memoir on the ſubject, we muſt refer the reader to the Doctor's own account for its particular arrangement; obſerving only that the catalogue ſubjoined comprehends nine conſtellations, which are arranged in al-

 phabetical

phabetical order, with the comparative brightnefs of the ftars accurately ftated. In a fubfequent paper, publifhed in the fame volume, he has completely verified the utility of his method by experience, and fhewn that there is no permanent change of luftre in the ftars. In the notes to his firft catalogue he mentioned α Herculis as a periodical ftar. By a feries of obfervations on this ftar, compared with κ Ophiuchi, which was moft conveniently fituated for his purpofe, he has been able not only to confirm this opinion, but to afcertain its period. His obfervations are arranged in a table, by means of which he determines that this ftar had gone through four fucceffive changes in an interval of 241 days; and therefore the duration of its period muft be about 60 days and a quarter. This fact concurs with other circumftances in evincing the rotatory motion of the ftars on their axes. "Dark fpots, or large portions of the furface, lefs luminous than the reft, turned alternately in certain directions, either towards or from us, will account for all the phenomena of periodical changes in the luftre of the ftars, fo fatisfactorily, that we certainly need not look out for any other caufe." If it be alleged that the periods in the change of luftre of fome ftars, fuch as Algol, β Lyræ, δ Cephei, and η Antinoi, are fhort, being only 3, 5, 6, and 7 days refpectively; while thofe of ο Ceti, and of the changeable ftar in Hydra, and that in the neck of the Swan, are long, amounting to 331, 394, and 497 days; and that we cannot afcribe phenomena fo different in their duration to the fame caufe—it may be anfwered to this objection, that the force of it is founded on our limited acquaintance with the ftate of the heavens. To the 7 ftars, the periodical changes of which were before known, we may now add α Herculis, which performs a revolution of its changes in 60 days.

"The ftep from the rotation of α Herculis to that of ο Ceti is far lefs confiderable than that from the period of Algol to the rotation of α Herculis; and thus a link in the chain is now fupplied, which removes the objection that arofe from the vacancy." The rotation of the fifth fatellite of Saturn is proved by the change obfervable in its light; and "this variation of light, owing to the alternate expofition of a more or lefs bright hemifphere of this periodical fatellite, plainly indicates, that the fimilar phenomenon of a changeable ftar arifes from the various luftre of the different parts of its furface, fucceffively turned to us by its rotatory motion."

Befides, we perceive a greater fimilarity between the fun and the ftars, by means of the fpots that muft be admitted to exift on their furfaces, as well as on that of the fun.

Dr Herfchel farther obferves, that the ftars, befides a rotatory motion on their axes, may have other movements; "fuch as nutations or changes in the inclination of their axes; which, added to bodies much flattened by quick rotatory motions, or furrounded by rings like Saturn, will eafily account for many new phenomena that may then offer themfelves to our extended views." To this paper is likewife fubjoined a catalogue of nine conftellations; and the author promifes to give the whole of them in fucceffive fhort catalogues on the fame plan.

CATAWESSY, a townfhip in Northumberland co. Pennfylvania, fituated on the S. E. bank of the E. branch of Sufquehannah River oppofite the mouth of Fifhing Creek, and about 20 miles N. E. of Sunbury. —*Morse.*

CATENARIA, or CATENARY CURVE. See *Encycl.* and ARCH in this *Supplement*.

CATHARINE II. emprefs of all the Ruffias, acted fo confpicuous a part on the theatre of the world; poffeffed fuch uncommon powers of mind, highly cultivated by fcience and literature; and was fuch a patronefs of fcience and literature in others—that it cannot be deemed foreign from a work of this nature to give fome account of the principal events of her more private life.

SOPHIA AUGUSTA FREDERICA, who, upon her marriage to the grandfon of Peter the Great, affumed the name CATHARINE ALEXIEVNA, was born at *Stettin* on the 2d of May 1729. Her father was Chriftian Auguftus, prince of Anhalt Zerbft-Dornburg, at that time major general in the Pruffian fervice, commander in chief of the regiments of infantry, and governor of the town and fortrefs of Stettin. Her mother, who was born princefs of Holftein Eutin, was a woman of great parts and beauty, of nearly the fame age with the prince royal of Pruffia, afterwards Frederic the Great, with whom fhe kept up a regular correfpondence, and who afterwards contributed to the aggrandifement of her daughter. This accomplifhed princefs took upon herfelf the care of educating the young Sophia, whom fhe brought up in the fimpleft manner, and would not fuffer to exhibit the leaft fymptoms of that pride to which fhe had fome propenfity from her earlieft childhood. The confequence of this falutary reftraint was, that good humour, intelligence, and fpirit, were even then the ftriking features of her youthful character. Being naturally addicted to reading, to reflection, to learning, and to employment, fhe was taught the French and other fafhionable languages; and was inftructed to read fuch books chiefly as might make her acquainted with hiftory and with the principles of fcience; whilft the doctrines of the Lutheran religion were carefully explained to her by a divine, who little thought how foon his illuftrious pupil would embrace another faith.

The emprefs Elizabeth, who then fwayed the fceptre of Ruffia, had in early life been promifed in marriage to the young prince of Holftein-Eutin, brother to the princefs of Anhalt Zerbft; but at the inftant when the marriage was about to be celebrated, the prince fell fick and died. Elizabeth, who loved him to excefs, became inconfolable, and in the bitternefs of her grief made a vow of celibacy. This vow, though fenfual, and even lafcivious, fhe kept fo far as never publicly to acknowledge any man as a hufband; and upon her afcending the throne of her anceftors, fhe called her nephew the Duke of Holftein Gottorp to her court, where he was folemnly proclaimed, when fourteen years of age, Grand Duke, with the title of Imperial Highnefs, and declared fucceffor to the Emprefs Elizabeth. To fecure the fucceffion in the family of Peter the Great, the Emprefs was very defirous to have her nephew married; and the princefs of Anhalt Zerbft, not ignorant of the tender remembrance which fhe ftill preferved for her brother, conceived the idea of placing, by means of it, her daughter on the throne of Ruffia. She communicated her plan to the king of Pruffia, who not only applauded it, but lent her his affiftance to carry it into execution.

Full

Catharine.

Full of ambitious hopes, therefore, the princefs repaired with her daughter to St Peterfburgh, where fhe was received with friendfhip by Elizabeth, and where the young Sophia foon made a confiderable impreffion on the mind of the Grand Duke. As Peter was well made, of a good figure, and, though uneducated, not deftitute of natural talents, the attachment became reciprocal; and the princefs of Zerbft, throwing herfelf at the feet of the emprefs, affured her, that the two lovers were attached to each other by a paffion unconquerable; and calling to her mind the love which fhe had herfelf borne to the prince of Holftein, conjured her to promote the happinefs of that prince's niece. The ftratagem fucceeded. The choice of Elizabeth was next day announced to the council and to the foreign minifters; and preparations were made for celebrating the marriage with a magnificence worthy of the heir of the throne of the Ruffias. In the mean time the Grand Duke was feized with the fmall pox, from which, though he recovered, it was with fuch a change of features, as rendered him, from being comely, almoft hideous, and converted the love of the young princefs of Anhalt, if indeed fhe ever felt for him that paffion, into horror and difguft. She was not, however, of a difpofition to let a disfigured countenance frighten her from a throne. She embraced the Greek religion, changed her name from Sophia Augufta Frederica to Catharina Alexievna, and with the entire approbation of Elizabeth was married to her nephew the Grand Duke.

For fome time this ill matched pair lived together, though without love, yet on terms apparently decent; but a mutual diflike gradually took place between them, which the courtiers quickly difcovered, and were at pains to foment into hatred. Peter was now ugly and his mind was uninformed. Catharine, if not a beauty, was at leaft a lovely woman, and highly accomplifhed. She could find no entertainment in his converfation, and he felt himfelf degraded by her fuperiority. A faction was formed at court, headed by the great chancellor Beftucheff, to exclude the Grand Duke from the throne, and to place Catharine at the head of affairs; and to accomplifh this end, every art was employed to fill the feeble mind of the emprefs with jealoufies of her nephew, and with a contempt of his character. He was reprefented at one time as extremely ambitious, and capable of the moft daring enterprifes, to get immediate poffeffion of the throne; and at another, as a wretch given up to drunkennefs and to every unprincely vice.

The confequence of the firft of thefe accufations was, that he was kept at a diftance from his aunt, and a ftranger to public affairs; and being wholly unemployed, that time which his education had not fitted him to fill up with reading, reflection, and rational converfation, hung fo heavy on his mind, that it was no difficult matter for thofe diffipated young men, who were placed about him for that very purpofe, to initiate him in the habits of drunkennefs and the other mean practices to which it was pretended he had long been devoted. In fuch a fchool, it was no wonder that he became a proficient in grovelling diffipation: or that, being unpolifhed, and even of rude manners, he chofe for his companions fome of the loweft of the people.

Catharine, in the mean time, languifhed for that happinefs which fhe could not find in the fociety of her hufband. She was fond of pleafure; but it was that comparatively refined pleafure which fhe had enjoyed at the court of Berlin. She loved balls, mufic, and elegant converfation, and could take no fhare in the drunken revels of Peter. Among the young men with whom he was furrounded, his chamberlain Soltikoff was particularly remarked for the elegance of his tafte and the graces of his perfon; and though yet fcarcely more than a boy in years, he was faid to have obtained the favours of feveral ladies of the court. Succefs had made him confident and ambitious; and his ambition prompted him to afpire at making a conqueft even of the Grand Duchefs. By ftudying her tafte, and contriving to amufe her, he was at laft fuccefsful; and obtained from her Imperial Highnefs every favour which he could wifh; but he enjoyed not his fortune with moderation, and his enemies contrived to get him placed in an honourable office at a diftance from the court. He was commiffioned to repair to Stockholm, with the title of Envoy Extraordinary, to notify to the king of Sweden the birth of Paul Petrovitch, of whom the Grand Duchefs had juft been delivered.* The prefumptuous Soltikoff, proud of the employment, fet off with hafte to Sweden, and left it with equal fpeed. But fcarcely had he quitted Stockholm, on the wings of love and ambition, when he was ftopped on the road by a courier, who put into his hands an order for him to go immediately to Hamburgh, and there to refide in the quality of minifter plenipotentiary from the court of Ruffia.

* Oct. 1. 1754.

Catharine for fome time preferved her attachment to the exiled chamberlain: but all at once the prefence of a ftranger, whom fortune had brought to the court of Ruffia, made her forget the lover whom fhe no longer faw. This perfon was Staniflaus Poniatowfky, the late king of Poland, who firft made his appearance at St Peterfburg in the train of the Britifh ambaffador, and very quickly gained the affections of the Grand Duchefs. In carrying on this intrigue, the lovers were not fo cautious as to deceive the eyes of the envious courtiers, who reported to the emprefs not only all that they faw, but whatever they fufpected. Elizabeth was incenfed, and commanded Poniatowfky to quit without delay the dominions of Ruffia. The accomplifhed Pole obeyed; but foon returned clothed with a character which made him in fome degree independent of the emprefs.

The Count de Bruhl, then prime minifter to the king of Poland, faw of what importance it was to his mafter to have a powerful intereft at the court of Ruffia. He was likewife no ftranger to the paffion which the Grand Duchefs entertained for Poniatowfky; and having got that nobleman decorated with the order of the White Eagle, he fent him back to St Peterfburgh in the quality of minifter plenipotentiary from the republic and king of Poland. Nor was this all that Bruhl did for the two lovers. Being informed by the chancellor Beftucheff, that the Grand Duke and Grand Duchefs were languifhing in a penury unworthy of their rank, he remitted to Poniatowfky 6000 ducats, to be employed in fuch a manner as he might judge beft for fecuring the favour of the prince and his confort. The ambaffador profited by thefe counfels and benefactions. He was already fure of the Grand Duchefs's heart, and he very quickly gained the favour of her hufband. He

talked

Catharine. talked English and German with him; drank, smoked, abused the French, and extolled the king of Prussia with unlimited praise.

The Grand Duchess was so blinded by her passion, that she was never without Poniatowsky in her company. She devoted to him the whole of her time; and she made this intimacy so little a secret, that public report was loud to her prejudice. In the mean time she was delivered of the Princess Anne†, who lived only fifteen months. The Grand Duke was the only person about court who seemed to know nothing of what was passing. His whole time was occupied in copying, with servile affectation, the air, the manners, the tone of the king of Prussia; and in dressing a little army at Oranienbaum in the Prussian uniform. His eyes, however, were at last opened. Some of the courtiers, from hatred to the chancellor, who countenanced the intrigue between the Grand Duchess and the Polish ambassador, roused his jealousy in order to destroy their enemy. They succeeded. He forbade his wife to be seen with Poniatowsky, and prevailed with the empress to deprive the chancellor of his office, and to banish him to an estate which he had 120 versts beyond Moscow.

† February 1758.

Catharine had now to support at once the aversion of her husband, the indignation of the empress, the insulting disdain of a court, which a few days before was lavish of its assiduities and smiles; and what afflicted her most of all, the dread of losing for ever her favourite Poniatowsky. Her courage, however, did not forsake her. Poniatowsky was indeed recalled, and left Russia, after suffering some deserved indignities from the Grand Duke, who about this time formed a connection with one of the daughters of the Senator Vorontzoff, brother to the new chancellor. This lady, Elizabeth Romanovna Vorontzoff, was elder sister to the Princess Dashkoff, who acted so conspicuous a part in the revolution which set the crown on the head of Catharine. She was beautiful, but vain; and possessed not either the wit or the understanding of her sister.

In the mean time the health of the empress visibly declining, Catharine was very desirous of being reconciled to her: but the irritated sovereign would listen to no accommodation, except on terms too humiliating for the haughty spirit of the Grand Duchess. Catharine, therefore, absented herself from court, and asked permission to retire into Germany. This, as she had foreseen, was refused. Elizabeth was too fond of the young Paul Petrovitch to permit the departure of his mother, and thereby expose him to the danger of being at some future period declared illegitimate. She took the Grand Duchess again into favour; and it is thought, that had she lived a little longer than she did, she would have excluded Peter from the throne, and declared Paul her immediate successor.

While the empress was meditating the aggrandizement of the young prince and his mother, the Grand Duke had conceived a plan for degrading them both. He had resolved, at the moment his aunt should close her eyes, to assemble his troops, to get himself proclaimed emperor, to repudiate the Grand Duchess, to declare the young Paul Petrovitch illegitimate, and publicly to marry his mistress Elizabeth Romanovna Vorontzoff. We have shown elsewhere (see Russia, n° 72. *Encycl.*) how this plan, when almost ready to be carried into execution, was betrayed to Catharine, who, ever since her caballing with the Chancellor Bestucheff, had resolved, by some means or other, to snatch the sceptre from the feeble hand of her husband. At present, we believe she was not acquainted with it; and though she had, she could not now have turned it to her advantage, as her party, ever since the disgrace of Bestucheff, was without a leader of any abilities.

Catharine.

Amid these distractions caused by the prospect of the death of the empress, and the known hatred of the Grand Duke and Duchess to each other, Count Panin, preceptor to the young prince, devoted himself entirely to Catharine. He wished to see her possessed of all the power of the empire; but he was afraid to proceed to the extremity to which she proposed to go, and to deprive Peter of the name of Emperor. He contrived therefore to procure an apparent reconciliation between the Grand Duke and his consort, as well as between him and his aunt Elizabeth; and he had almost persuaded the silly prince not to assume the sovereign power on the death of the empress, till he should be solemnly invested with it by a decree of the senate. Could he obtain this point, he knew that the power of Peter would be limited, and the authority secured to his wife and his son. He was, however, disappointed. Catharine herself disapproved of this plan, and concurred with the real friends of her husband in advising him "to conform to established custom in assuming the reins of empire."

He had hardly received this advice when word was brought him that the Empress Elizabeth was dead (A); and the courtiers pressed in crowds about him. He accosted them with dignity, received the oaths of the officers of his guard, and seemed at once to have laid aside his weakness. In an hour he got on horseback, traversed the streets of St Petersburg, and distributed money among the multitude and the soldiers. He had been so treated by his aunt, that he could not possibly be grieved at her death; but in paying the last duties to her remains, he betrayed no indecent elation. The first actions of his reign were prudent and patriotic, and such as would have done honour to a greater prince. He appeared to be reconciled to his wife, in whose company he spent much of his time; he recalled from prison and banishment 17,000 persons, some of them of rank and of great talents, who had been the victims of Elizabeth's jealous timidity; he permitted the nobility to bear arms or not at their own discretion, freeing them at the same time from the extreme servitude under which they had been held by his immediate predecessors; and he abolished *the secret committee*, an infamous inquisitorial tribunal, which ever since the reign of the father of Peter the Great had been the chief engine of Russian despotism.

He neglected, however, one thing; which, among the people over whom he was appointed to reign, would have contributed more to the security of his throne than all the wise and beneficent edicts which he had published. He made no preparations to be crowned at Moscow. Instead of complying with this ancient ceremony, and humouring the prejudices of his superstitious subjects,

---

(A) Christmas-day 1761 according to the Russian calendar, or the 5th of January 1762 according to ours.

Catharine.

jects, he thought of nothing but of war with Denmark, and of a personal interview with the king of Prussia in Germany. His admiration of that great monarch hurried him indeed into the most extravagant follies. Not contented with giving him peace, and entering into an offensive and defensive alliance with him, he had the meanness to solicit a commission in his army, and to accept of the rank of major-general. Of this title he seemed more vain than of that of Emperor of all the Russias. He constantly wore the Prussian uniform; introduced among his troops the Prussian discipline, which, though better than their own, was disagreeable, because it was new, and much more because it was German; and he raised his uncle, a man of no military talents, and a foreigner, to the dignity of generalissimo of the Russian armies; giving him at the same time the particular command of the horse-guards, a body of men which had never before been under any command but that of the supreme head of the empire. Nor did his infatuated predilection for Germany, a country abhorred by the Russians, stop even here: He disbanded the noble guards which had placed Elizabeth on the throne, dismissed the horse-guards from the service which they performed at court, and substituted his Holstein guards in their place.

Whilst he was thus alienating from himself the affections of the army, he contrived to disgust another order of men, whose attachment he should have laboured above all things to retain. He was at pains to shew his preference of the Lutheran faith and worship to the doctrines and ceremonies of the Greek church; he attempted to make some alterations in the dress of the monks; he annexed great part of the possessions of the church to the domains of the crown; and he banished the archbishop of Novogorod, who opposed these innovations; and found himself obliged suddenly to recal him.

He had now returned to his former courses. He shut himself up for whole days with his mistress and drunken companions; he compelled the nobility and ladies of the court to sit in company with buffoons and comedians; he insulted every foreign minister but the ministers of Great-Britain and Prussia; and he made no secret of his intention to repudiate the empress, declare Paul Petrovitch illegitimate, and marry the Countess Vorontzoff. Convinced, however, as it would seem, that he could not be a father, he resolved to adopt Prince Ivan, the descendant of the elder brother of Peter the Great, whom Elizabeth had dethroned and confined in prison, to declare him his successor, and to unite him in marriage with the young princess of Holstein Beck, who was then at St Petersburgh, and whom he cherished as his daughter.

This inconsistent and weak conduct of the emperor turned the attention of all orders of men to the empress, who made it her sole employment to gain those hearts which he was losing. Instructed from her infancy in the arts of dissimulation, it was not difficult for her to affect, in the sight of the multitude, sentiments the most foreign to her mind. The pupil of the French philosophers put on the air of a bigot to the most superstitious ceremonies of the Greek religion, and treated the ministers of that religion with the profoundest reverence. And whilst her husband was getting drunk amidst a rabble of buffoons, and disgusting every person of decency who approached him, she kept her court with a mixture of dignity and affability, which attracted to her all who, by capacity, courage, or reputation, were capable of serving her.

Catharine.

Correct, however, as her public conduct appeared, her private life was not less licentious than formerly. While yet Grand Duchess, she had formed a very tender connection with Gregory Orloff, a man of mean birth, and of no education, but possessed at once of personal beauty and the most daring courage. He had an inferior commission in the artillery, while his two brothers were common soldiers in the regiments of guards. The intrigue which she carried on with him was known only to one of her women named Catharine Ivanovna; nor did Orloff himself for some time suspect the rank of the lady who so lavishly conferred upon him her favours in secret. At last finding him intrepid and discreet, she discovered herself, unveiled to him all her ambitious designs, and easily prevailed with him and his brothers to enter with zeal into her conspiracy against the emperor. Orloff likewise gained over Bibikoff his friend, a Lieutenant Passick, with other officers; and by their means easily seduced some regiments of the guards. The Princess Dashkoff was strongly attached to Catharine, we believe, from worthy motives, and had frequent meetings with Orloff on the business of the conspiracy, without suspecting that he was so much as known to the empress. Count Panin, too, and the Hetman of the Kossacks, were determined to tumble Peter from the throne; but they were not inclined to go all the lengths proposed by Catharine and her two favourites. Hoping to enjoy the actual power of the empire themselves, they were for declaring Paul Petrovitch emperor in the room of his father, and conferring upon his mother the name and authority only of regent; while the princess and Orloff, knowing the sentiments and wishes of the empress, were resolved to vest her with sovereign power, or to perish themselves in the hazardous attempt.

In the mean time the anniversary of the patron saints of Russia was at hand, when Peter had determined, at the conclusion of the festival, to divorce the empress, shut her up in prison, declare her son illegitimate, and publickly marry his mistress. As they who plan a conspiracy are always more vigilant than those against whom it is directed, the friends of Catharine were carefully informed of all that passed about the emperor, whilst he was kept in total ignorance of their proceedings. It was therefore necessary for them to unite in the same plan, and to carry it quickly into execution; for delay or divisions would involve them all in one common ruin. The empress contrived to bring over the Hetman entirely to her views; and the Princess Dashkoff, by the sacrifice, it has been said, of her charms, found little difficulty in reconciling Count Panin to the same measures. They now agreed to seize the Tzar on his arrival at Peterhoff, an Imperial palace on the shore of the Gulf of Cronstadt, where he proposed to celebrate the approaching festival; and they were waiting impatiently for the moment of action, when all at once their plot was discovered.

Passick, who has been mentioned among the conspirators, had gained the soldiers of the company of guards in which he was a lieutenant; but one of them, who thought that his captain was in the secret, asked that officer

Catharine. officer one evening, When they were to take up arms against the emperor? The captain, surprised, had recourse to dissimulation, and easily drew from the soldier all that he knew of the conspiracy. It was nine o'clock at night. Passick was put under arrest; but found means to slip into the hands of a man who had been placed as a spy over him by the Princess Dashkoff, a scrap of paper containing these words, " Proceed to execution this instant, or we are undone." The man was desired to carry it to the Hetman, by whom he would be handsomely rewarded; but he hurried with it to the princess, who instantly communicated the intelligence to the other conspirators. She herself put on man's apparel, and hastened to the place where she was accustomed to meet Orloff and his friends; where she found them, as impatient as herself to carry their plot into immediate execution.

During this awful crisis the empress was at Peterhoff, at the distance of 25 versts from St Petersburgh; and one of the brothers of Gregory Orloff, named Alexius, undertook to find her out, whilst he himself, with his other brother and Bibikoff his friend, repaired to the barracks for the purpose of instructing the soldiers of their party how to act on the first signal. Alexius Orloff carried with him a short note from the Princess Dashkoff, but neglected to deliver it; and the empress, being suddenly roused from a sound sleep, was much alarmed, when she saw at the side of her bed a soldier of whom she knew nothing. Her alarm was increased when the stranger said, " Your majesty has not a moment to lose; get ready to follow me;" and instantly disappeared. She rose, however, and calling her woman Ivanovna, they disguised themselves in such a manner that they could not be known by the sentinels about the palace; and the soldier returning, they hurried with him to a coach which was waiting at the garden gate. Orloff took the reins, but drove with such fury that the horses soon fell down; and they were obliged to travel part of the way on foot. They had not, however, gone far, when they met a light country cart; and she who was aspiring to the throne of the greatest empire in the world, was glad to enter the capital of that empire in this humble vehicle.

It was seven in the morning when she arrived in St Petersburgh: and to the soldiers, who gathered about her in great numbers, she said, that " her danger had driven her to the necessity of coming to ask their assistance; that the Tzar had intended, that very night, to put her and her son to death; and that she had so great confidence in their dispositions, as to put herself entirely into their hands." They immediately shouted, " Long live the empress!" And the chaplain of one of the regiments fetching a crucifix, received their oaths of fidelity.

The troops, however, were not unanimous in this revolt. Though Gregory Orloff was treasurer of the artillery, and well enough beloved by the soldiers, that corps refused to follow him until he should produce the orders of Villebois their general; and that officer, withheld either by fidelity to the emperor or by fear, presumed to speak to Catharine of the obstacles which yet remained for her to surmount; adding, that she ought to have foreseen them. She haughtily replied, that " she had not sent for him to ask what she ought to have foreseen, but to know how he intended to act." " To obey your majesty," returned Villebois; and putting himself at the head of his regiment, he immediately joined the conspirators. So ripe indeed were the minds of all men for this revolt, that in the space of two hours the empress found herself surrounded by 2000 warriors, together with great part of the inhabitants of Petersburgh; and with that numerous train of attendants she repaired to the church of Kasan, where the archbishop of Novogorod, setting the Imperial crown on her head, proclaimed her sovereign of all the Russias, declaring, at the same time, Paul Petrovitch her successor.

Matters had now proceeded by much too far to admit of any compromise between Catharine and her husband: but had the infatuated Tzar put his affairs wholly into the hands of Marshal Munich, that intrepid veteran would have tumbled the empress from her throne almost as quickly as she had got possession of it. He acted, however, a very different part. Upon receiving intelligence of what had been done at St Petersburgh, he asked indeed the Marshal's advice, but suffered himself to be guided by his mistress and timid companions. Through their terrors and his own irresolution opportunities were lost which could never be recovered; for though his Holstein guards, with tears in their eyes, swore that they were all ready to sacrifice their lives in his service, and though the old Marshal offered to lead them against the rebels, saying to the emperor, " I will go before you, and their swords shall not reach you till they have pierced my body," he was persuaded to treat with the empress, to acknowledge his misconduct, and to offer to share with her the sovereign power. At last he was weak enough to abandon his troops, and to surrender at discretion to his consort; whose creatures hurried him from Oranienbaum to Peterhoff, stripped him of all his clothes, and after leaving him for some time in his shirt, a butt to the outrages of an insolent soldiery, threw over him an old morning gown, and shut him up alone, with a guard at the door of his wretched apartment. On the 29th of June, O. S.* 1762, Count Panin was sent to him by the empress; and after a long conference, prevailed with him to write and sign a solemn resignation of his crown, and a declaration of his utter incapacity to govern so great an empire.

* July 10.

The revolution was now complete, and Peter seemed to enjoy some composure of mind; but in the evening he was carried a prisoner to Ropscha, a small Imperial palace, at the distance of 20 versts from Peterhoff, where he was murdered on the 17th of July, just one week after his deposition. Of the manner of his death different accounts have been given. By some he is said to have been poisoned; by others, to have been strangled by one of the Orloffs; and a few have thought that he perished by the same means as Henry VI. of England. Whether the empress was accessary to his death is not known; though it is certain, that so far from making any inquiry after his murderers, she affected to believe that he had died naturally of the *piles!*

The first care of Catharine was to reward those who had been the principal actors in the revolt. Panin was made prime minister; the Orloffs received the title of Count; and the favourite Gregory was appointed lieutenant-general of the Russian armies, and knight of the order of St Alexander Nefsky, the second order of the empire. Several officers of the guards were promoted, of whom 24 received considerable estates; and among the

Catharine. the soldiers, whom ſhe treated with the greateſt affability, brandy and beer were liberally diſtributed. The chancellor Beſtucheff, who had been the moſt inveterate enemy of Peter, was recalled from his exile, reſtored to his rank of field-marſhal, and had an annual penſion ſettled upon him of 20,000 rubles. To the friends of the emperor ſhe behaved with great moderation. Prince George, whom he had conſtituted Duke of Courland, was indeed obliged to renounce his title; but the adminiſtration of Holſtein was committed to him, and he ever after ſerved the empreſs with zeal and fidelity.

The news of the revolution was ſoon ſpread over Europe; and none of the ſovereigns, though they knew by what ſteps Catharine had mounted the throne, heſitated for a moment to acknowledge her title. She was not, however, at perfect eaſe in her own mind; nor was her right recogniſed by all her ſubjects. Tho' ſhe publiſhed manifeſtos, ſetting forth the intentions of the late emperor towards her and her ſon, which made reſiſtance neceſſary; though in theſe papers ſhe attributed her elevation to the wiſhes of her people and the providence of God; and though ſhe called upon all who were ſincerely attached to the orthodox faith of the Greek church, to conſider the ſudden death of Peter as the judgment of heaven in favour of the revolution; yet in the diſtant provinces no exultations were heard; both ſoldiers and peaſants obſerved a gloomy ſilence. Even at Moſcow, ſo great was the diſaffection to Catharine's government, that it was ſome time before ſhe could venture to go to that city to be crowned; and ſhe found in it at laſt ſo cold a reception, that ſhe very quickly returned to St Peterſburgh.

Nor was this the only cauſe of her uneaſineſs. The connection between Orloff and her became viſible, and gave juſt offence to her other friends. The princeſs of Daſhkoff firſt perceived it; and when ſhe preſumed to expoſtulate with the empreſs on the meanneſs and imprudence of her paſſion, ſhe was baniſhed from the court to Moſcow. Count Panin and the Hetman ſaw with indignation that they had dethroned the grandſon of Peter the great, to aggrandiſe a rude and low born upſtart. Cabals and conſpiracies were entered into by high and low, both againſt Catharine and againſt her favourite; and it required all her abilities and firmneſs to preſerve at once her throne and her lover. On one occaſion ſhe hoped to obtain from the Princeſs Daſhkoff ſufficient proof that Panin and the Hetman of the Koſſacks were concerned in a plot which had juſt been diſcovered; and with this view ſhe wrote to her a letter of four pages, filled with the moſt tender epithets and the moſt magnificent promiſes, conjuring her in the name of their long ſtanding friendſhip, to reveal what ſhe knew of the recent conſpiracies. With becoming magnanimity, the princeſs replied, "Madam, I have heard nothing; but if I had heard any thing, I ſhould take good care how I ſpoke of it. What is it you require of me? That I ſhould expire upon a ſcaffold? I am ready to mount it."

Catharine, deſpairing of conquering ſuch a ſpirit, attempted to attach to her thoſe whom ſhe dared not to puniſh. Some of the inferior conſpirators were baniſhed to Siberia, while Panin and the Hetman, whom ſhe moſt dreaded, received additional marks of her favour. In the mean time, to gain the affections of the people at large, ſhe paid the utmoſt attention to the adminiſtration of juſtice; formed magnificent eſtabliſhments for Catharine. the education of the youth of both ſexes; founded hoſpitals for orphans, for the ſick, and for lying-in women; invited foreigners of all nations, poſſeſſed of any merit, to ſettle in different parts of her vaſt territories; increaſed the naval force of the empire; and gave ſuch encouragement to the cultivation of every elegant and uſeful art, that in the ſhort ſpace of a year and a half from her acceſſion to the throne, the national improvement of Ruſſia was viſible.

In the good fortune and glory of Catharine, no one rejoiced more ſincerely than Count Poniatowſky. He approached towards the confines of Ruſſia, and wrote to her in the tendereſt ſtyle of congratulation, requeſting permiſſion to pay his reſpects to her in the capital of her empire. It is not improbable that he flattered himſelf with the hopes that ſhe would give him her hand in marriage, and thus raiſe him to the throne of the Tzars; but ſhe had promiſed to the Empreſs Elizabeth, that ſhe would never again ſee the count; and to that promiſe ſhe at preſent adhered. She wrote to him, however, in the moſt affectionate terms; and tho' ſhe gave him no encouragement to repair to St Peterſburgh, ſhe aſſured him that ſhe had other proſpects in view for his aggrandiſement, and that he might depend upon her perpetual friendſhip: and ſhe ſoon appeared to be as good as her word. On the death of Auguſtus III. ſhe raiſed her former favourite to the throne of Poland, in oppoſition to the wiſhes of the courts of Vienna and Verſailles, as well as of a great majority of the Poliſh nobles. She defeated the intrigues of the two foreign courts by more ſkilfully conducted intrigues of her own; and, by pouring her armies into the republic, ſhe ſo completely overawed the nuncios, that Poniatowſky was choſen by the unanimous ſuffrages of the diet which met for the election of a ſovereign; and, on the 7th of September 1764, was proclaimed King of Poland and Grand Duke of Lithuania, by the name of Staniſlaus Auguſtus.

Whilſt ſhe was thus diſpoſing of foreign kingdoms, ſhe was kept under perpetual dread of being tumbled from the throne of her own vaſt empire. Her want of title to that throne was now ſeen by all ranks of her ſubjects; the good qualities of Peter the third were remembered, and his failings and faults forgotten. His fate was univerſally lamented; and, except the conſpirators, who may be ſaid to have embrued their hands in his blood, there was hardly a Ruſſian who did not regret that the ſovereignty had paſſed from the ancient family of the Tzars to a foreigner, allied only by marriage to the blood royal. Even the conſpirators themſelves had loſt much of their regard for Catharine. The princeſs of Daſhkoff was a ſecond time baniſhed to Moſcow; and, to magnify her own importance, ſhe ſpoke freely of the means by which the empreſs, whom ſhe accuſed of ingratitude, had been raiſed to the throne. The inhabitants of Moſcow, who never favoured the uſurpation, were thus made ripe for a revolt. At St Peterſburgh, Count Panin felt himſelf uneaſy under the predominant influence of the favourite, and tried in vain to divert Catharine's affections to a new object. She received a few ſecret viſits from a handſome young man, and then appointed him to a lucrative and honourable employment in ſome diſtant province of the empire; when Orloff recovered his former

Catharine. mer afcendency, which through his own careleffnefs he had nearly loft. In this ftate of the public mind, confpiracies were very frequent; and as the general object of them was to place on the throne prince Ivan, who was again languifhing in the dungeon from which Peter had taken him, the emprefs had given to his guard an order, figned by her own hand, to put that unfortunate prince to death, fhould any attempt be made to liberate him from his prifon. An attempt was made by a very inferior officer, as fome have fuppofed, by the inftructions of Catharine, and her bloody order was inftantly obeyed. The affaffins were rewarded and promoted in the army; but the officer who attempted to refcue the prince was condemned to death, and fuffered unexpectedly the fentence of the law. The brothers and fifters of Ivan, who had been kept in a prifon different from his, were fent to Denmark; and, to provide them with neceffaries fuitable to their rank, the emprefs made them a prefent of 200,000 rubles, and paid annually to the maintenance of their dignity a penfion of thirty thoufand.

The throne of Catharine was now firmly eftablifhed by the death or renunciation of every perfon who was defcended of the imperial family; and fhe had leifure to turn her thoughts to the aggrandifement of the empire. It was foon feen that this was the object which fhe had in view when fhe raifed Count Poniatowfky to the throne of Poland, and that fhe was not actuated on that occafion by any remains of her former attachment. We have elfewhere fhewn (fee Poland, *Encycl.* n° 98—115) under what pretences fhe invaded the kingdom of him who had formerly been one of her moft favoured lovers, and by what means fhe annexed great part of it to the territories of Ruffia. But it is not through her wars that in this article we mean to trace her character: It is not as a fovereign and heroine that her life is entitled to a place in a general repofitory of arts, fciences, and mifcellaneous literature, but as a patronefs of art and of fcience, and as the legiflatrix of a vaft empire, who employed all her talents and all her power for the civilization of a great part of the human race.

Under the article Russia *(Encycl.)*, we have mentioned the famous *code of laws for a great empire*, and the propofed *convention of deputies from all the claffes*, which Catharine and the princefs Dafhkoff fo artfully employed as means to bring about the revolution which feated the former on the throne. The ftates actually met in the ancient capital of the empire, and the fovereign's inftructions for framing a new code of laws was read amidft reiterated burfts of applaufe. All prefent extolled the fagacity, the wifdom, the humanity of the emprefs; but fear and flattery had a greater fhare in thefe exclamations than any juft knowledge of the fubject. The deputies of the Samoiedes alone had the courage to fpeak freely. One of them ftood up, and, in the name of himfelf and his brethren, faid, "We are a fimple and honeft people. We quietly tend our reindeer. We are in no want of a new code; but make laws for the Ruffians, our neighbours, that may put a ftop to their depredations." The following fittings did not pafs fo quietly. A debate about the liberation of the boors was carried on with fuch warmth, that fatal confequences were to be apprehended; and the deputies were difmiffed to their refpective provinces in the manner which we have elfewhere related. Previous, however, to the diffolution of this affembly, the members were required to fignalize the meeting by fome confpicuous act of gratitude; and, by a general acclamation, the titles of Great, Wise, Prudent, and Mother of the Country, were decreed to the emprefs. With affumed modefty fhe accepted only of the laft, "as the moft benign and glorious recompence for her labours and folicitudes in behalf of a people whom fhe loved."

For that people fhe did indeed labour, and labour moft ufefully. She introduced into the adminiftration of juftice the greateft reformation of which the half civilized ftate of Ruffia would perhaps admit. She fpared neither trouble nor expence to diffufe over the empire the light of fcience, and the benefits of ufeful and elegant arts; and fhe protected, as far as fhe could, the poor from the oppreffions of the rich. About the middle of 1767, fhe conceived the idea of fending feveral learned men to travel through the interior of her vaft dominions, to determine the geographical pofition of the principal places, to mark their temperature, and to examine into the nature of their foil, their vegetable and mineral productions, and the manners of the people by whom they were inhabited. To this employment fhe appointed Pallas, Gmelin, Euler, and many others of the higheft eminence in the republic of letters; from whofe journals of thefe interefting travels large additions have been made to the general ftock of ufeful knowledge. This furvey of the empire, and the maps made from it, had Catharine done nothing elfe, would alone have been fufficient to render her name immortal. Well convinced in her own mind, that it is not fo much by the power of arms, as by precedence in fcience, that nations obtain a confpicuous place in the annals of the world, with a laudable zeal fhe encouraged artifts and fcholars of all denominations. She granted new privileges to the two academies of fciences and the arts; encouraged fuch of the youth as had behaved well in thefe national inftitutes, to travel for farther improvement over Europe, by beftowing upon them, for three years, large penfions to defray their expence; and, to remove as much as poffible the Ruffian prejudice againft all kinds of learning, fhe granted patents of nobility to thofe who, during their education, had conducted themfelves with propriety, and become proficients in any branch of ufeful or elegant knowledge. Still farther to encourage the fine arts in her dominions, fhe affigned an annual fum of 5000 rubles for the tranflation of foreign literary works into the Ruffian language.

In the year 1768, the fmall-pox raged at St Peterfburgh, and proved fatal to vaft numbers of all ranks and of every age. The emprefs was defirous to introduce the practice of inoculation among her fubjects; and refolved to fet the example by having herfelf and her fon inoculated. With this view, fhe applied for a phyfician from England: and Dr Thomas Dimfdale of Hertford being recommended to her, he repaired with his fon to the capital of Ruffia, where he inoculated firft the emprefs, then the grand duke, and afterwards many of the nobility. The experiment proving fuccefsful, he was created a baron of the empire, appointed actual counfellor of ftate, and phyfician to her imperial majefty, with a penfion of L. 500 fterling a-year, a-year, to be paid him in England, befides L. 10,000 which he immediately received. So popular was the emprefs at this period, that, by a decree of the fenate, the anniverfary of her recovery from the fmall-pox was enjoined to be celebrated as a religious feftival; and it has ever fince been obferved as fuch.

She was now engaged in war with the Turks, of which a fufficient account for a work of this nature has been given under the title TURKEY *(Encycl.)*; but there was one tranfaction of her and her friends, of which no mention was made in that article, though it is of importance to him who would form a juft eftimate of her perfonal character.

We have noticed the fenfuality of the emprefs Elizabeth. She bore three children to the grand veneur Alexy Gregorievitch Razumoffky, to whom, indeed, fhe is faid to have been clandeftinely married. Of thefe children the youngeft was a girl, brought up under the name of princefs Tarrakanoff. Prince Radzivil, who has been mentioned in the article POLAND *(Encycl.)*, irritated at Catharine's cruelties to his countrymen, conceived the project of placing the young princefs on the throne of her anceftors; and, having gained over the perfons to whom her education was entrufted, he carried her off to Rome as a place of fafety. Catharine, in return, feized his large eftates; and he and the princefs were reduced to extreme poverty. Radzivil repaired to Poland in order to learn what could be done to forward his great enterprife; and fcarcely had he arrived there when an offer was made to reftore to him his poffeffions, upon condition of his carrying his ward to St Peterfburgh. This he refufed; but had the bafenefs to promife, that he would give himfelf no farther concern about the daughter of Elizabeth; and he was put in poffeffion of all his eftates.

By the inftructions of the emprefs, Alexius Orloff, who nominally commanded the Ruffian fleet at the Dardanelles, repaired to Rome, got accefs to young Tarrakanoff, and found means to perfuade her that all Ruffia was ready to revolt from Catharine, and place her on the throne of her mother. To convince her of his fincerity, he pretended to feel for her the tendereft and moft refpectful paffion; and the unfufpicious lady was induced to accept of him as a hufband. The ruffian who had affaffinated the grandfon of Peter the Great, did not hefitate to feduce and betray his granddaughter. Under pretence of having the marriage ceremony performed according to the rites of the Greek church, he fuborned fome fubaltern villains to perfonate priefts and lawyers; thus combining profanation with impofture againft the unprotected and too confident Tarrakanoff.

Having been treated for fome days, both at Rome and at Leghorn, with all the refpect due to a fovereign, the unfufpecting princefs expreffed a wifh to go on board a Ruffian fhip of war. This was juft what Orloff wanted. Attended by a numerous and obfequious train, fhe was rowed from the fhore in a boat with magnificent enfigns, hoifted upon the deck of the fhip in a fplendid chair, and immediately handcuffed. In vain did fhe throw herfelf at the feet of her pretended hufband, and conjure him by every thing tender which had paffed between them. She was carried down into the hold; the next day the veffel failed for St Peterfburgh; where, upon her arrival, the princefs was fhut up in the fortrefs; and what became of her fince was never known. Such were the means which Catharine fcrupled not to employ in order to get rid of all pretenders to her throne.

Soon after this fervice rendered to her by Alexius Orloff, fhe difmiffed his brother Gregory from her favour, and connected herfelf with Vaffiltchikoff, a fub-lieutenant of the guards. The former favourite had indeed become infolent, and, as Catharine thought, ungrateful. He afpired to nothing lefs than the throne. From love to himfelf and to a fon which fhe had born to him, fhe offered to enter into a fecret marriage; but with this propofal the proud prince (A) was not fatisfied, and hoped that his refufal would impel her to receive him publicly as her hufband and partner in power. He was miftaken. She divefted him of all his employments; but gave him a penfion of 150,000 rubles, a handfome fervice of plate, and an eftate with 6000 peafants upon it; and, thus enriched, he fet out upon a journey through various parts of Europe. He returned, however, much fooner than was expected; the new favourite was handfomely rewarded, and fent to a diftance; Orloff was reftored to all his offices, and his baleful influence was again felt.

He attempted to perfuade the emprefs to difmifs Panin from the court; but the grand duke interpofed in behalf of his old preceptor; and, for once, Catharine liftened to the entreaties of her fon. When a dreadful rebellion, under a Koffak of the name of Pugetfhoff, who pretended to be Peter III. efcaped from his affaffins, was fhaking the throne to its foundation—the influence of Orloff was fuch as to prevent the emprefs, for fome time, from employing her ableft general againft the rebels, becaufe that general was Panin, brother to the minifter. Danger, however, at laft prevailed over the favourite: Panin was fent againft Pugetfhoff; the rebellion was crufhed; and Catharine found leifure to give fomething like a legal conftitution to the empire. In that work, the laws and regulations eftablifhed for the government of the various provinces, and for the equitable adminiftration of juftice through the whole of her vaft dominions, evinces the greateft wifdom and fagacity in their author, as well as a proper regard to the practicable liberties and rights of men. In the capital, fhe eftablifhed the moft perfect police, by which the internal tranquillity of a great city was, perhaps, ever maintained; and whilft her private conduct was far from correct, fhe was acting in the capacity of fovereign, fo as to deferve, indeed, the appellation of *Mother of her people.*

To follow her through all her wars and intrigues with foreign courts, would fwell this article to the fize of a volume. Such a narrative, too, belongs rather to the hiftory of Ruffia than to the memoirs of Catharine; in which it is the bufinefs of the biographer to develope the private character of the woman rather than to detail the exploits of the fovereign. Her partition of Poland, and afterwards the annihilation of it as an independent

(A) She had fome time before obtained for him a patent, creating him a prince of the Roman empire.

Catharine. dependent republic; her encroachments on the territories of the grand fignior; her formation of the armed neutrality; the influence which fhe maintained over the courts of Sweden and Denmark; and the art with which fhe threw the weight of Ruffia fometimes into the fcale of Auftria, and fometimes into that of Pruffia, juft as the interefts of her own dominions required the one or the other to preponderate—fhew how admirably fhe was qualified to guide the helm of a great empire in all its tranfactions with foreign ftates. We fpeak not of the equity of her proceedings; for it muft be confeffed, that equity formed no barrier againft her ambition; and that fhe never failed to fubjugate thofe whom fhe pretended to take under her protection. Her ruling paffion was to enlarge her own territories, already fo very extenfive; and, for the attainment of that object, fhe contrived the moft judicious plans, which fhe executed with vigour. In this part of her conduct, however, fhe has been equalled by other monarchs; but in the zeal and the wifdom with which fhe endeavoured to introduce among her half-favage fubjects the bleffings of knowledge and induftry, fhe ftands unrivalled, except, perhaps, by her predeceffor Peter the Great. Of this we need bring no other proof, in addition to what has been already ftated, than that fhe founded in St Peterfburgh alone thirty-one feminaries, where 6800 children of both fexes were educated at the annual expence to the government of 754,335 rubles. She fuperintended herfelf the education of her grandchildren, and wrote for them books of inftruction. If it be true, that "every man acquainted with the common principles of human action, will look with veneration on the writer who is at one time combating Locke, and at another making a catechifm for children in their fourth year;" with what veneration fhould we look upon the emprefs of Ruffia, could we forget the means by which fhe obtained that elevation from which fhe frequently defcended for a fimilar employment? This fhe did, not for her own defcendants alone, but alfo for the children of others; of whom fhe had always a great number in her apartments, who fhared in the inftruction given to her grandchildren, and whofe careffes fhe returned with extreme complaifance.

Her greateft weaknefs was furely that grofs paffion which her panegyrifts have dignified with the name of love: but to fuch an appellation it had no claim, if love be any thing more than a fexual appetite. Befides Gregory Orloff, fhe had not fewer than ten favourites after the death of her hufband; and of thefe fhe feems to have felt a refined affection for none but Lanfkoi, a young Pole of a very ancient family, and of elegant manners, and the famous Potemkin, to whom fhe is faid fecretly to have given her hand, and who preferved her friendfhip, if not her affection, to the end of his life. To Lanfkoi, whofe education had been much neglected, fhe condefcended to become preceptrix; and, as he made great progrefs in the acquifition of ufeful knowledge, fhe admired in him her own creation. Potemkin, though not amiable, deferved her favour for the fidelity and abilities with which he ferved her, both in the council and in the field; and in him, when fhe had ceafed to look on him with the eyes of love, fhe refpected the intriguing politician and intrepid commander, who had formed plans for driving the Turks out of Europe, and fetting her on the throne of Byzantium. Her other favourites had nothing to recommend them but mafculine beauty and corporeal ftrength. One of them, however, thought it neceffary to have a library in the grand houfe, of which the emprefs, upon receiving him into favour, had made him a prefent; and defired the principal bookfeller to fill his fhelves. The man afked him what books he would pleafe to have. "You underftand that better than I (replied the favourite); that is your bufinefs. You know the proper affortments; I have deftined a large room to receive them. Let there be large books at the bottom, and fmaller and fmaller up to the top; that is the way they ftand in the emprefs's library!" In the converfation of fuch men, the cultivated mind of Catharine could enjoy no interchange of fentiments. Catharine.

We know not whether that more than Afiatic magnificence, which fhe difplayed on every public occafion, fhould be confidered as an inftance of weaknefs or of wifdom. If fhe delighted in balls, and mafquerades, and fumptuous entertainments, and drefs loaded with jewels and every kind of fplendid ornament, for their own fakes, fhe betrayed a weaknefs unworthy of that fovereign who held in her hand the balance of Europe, and at whofe nod the greateft powers of Afia trembled: but if fhe introduced fuch fplendour into her court merely to divert the attention of the Ruffians from the means by which fhe got poffeffion of the throne, and to wean them from their own favage and flovenly manners; even this may perhaps be confidered as one of her moft mafterly ftrokes in politics.

Her ambition was boundlefs; but, if fuch a phrafe may be allowed, it was not always true ambition. When the French republic had eftablifhed itfelf on the ruins of monarchy, and was propagating new theories of government through all Europe, true ambition would furely have led the autocratrix of the north to unite her forces with thofe of the coalefced powers, in order to crufh the horrid hydra before its anarchical principles could be introduced among her own barbarous fubjects. Such would certainly have been the advice of her favourite Potemkin, who longed to lead a Ruffian army into France, even before the murder of the unfortunate Louis. That general, however, had died in October 1791; and when Britain, Auftria, and Pruffia, were leagued againft the new republic, Catharine looked coolly on, in hopes, it is probable, of availing herfelf of their weaknefs, when exhaufted by a long and bloody war. She gave refuge, indeed, in her dominions to many emigrants from France, and fent a fquadron of fhips to co-operate with the navy of England: but in this laft meafure fhe regarded merely her own immediate intereft; for her crazy fhips were repaired by Britifh carpenters at the expence of the Britifh government, and her officers had an opportunity of learning the evolutions of the Britifh navy. She had likewife other profpects in view when fhe lent to the allies this flender aid. She meditated a new war with Turkey; and, depending upon meeting with no oppofition, if fhe fhould not receive affiftance from England and Auftria, fhe flattered herfelf with accomplifhing her darling project of driving the Ottomans out of Europe, and of reigning in Conftantinople. But fhe was difappointed. On the morning of the 9th of November 1796, fhe was feized with what her principal phyfician judged a fit of apoplexy; and, at 10 o'clock in the evening

evening of the following day, expired, in the 68th year of her age, leaving behind her the character of one of the greateft fovereigns that ever fwayed a fceptre.

After this long detail of the incidents of her life, it is needlefs to inform the reader that Catharine II. had no religion, and, of courfe, no principles of morality, which could induce her in every inftance to do to others as fhe would have them do to her. She was a profeffed difciple of the French philofophers; by fome of whom fhe was ridiculed, and by others cheated. The incenfe which fhe paid to the genius of Voltaire did not hinder him from frequently breaking his jefts upon the autocratrix of Ruffia and her fucceffive favourites; and Diderot, whom fhe careffed, fold to her an immenfe library, when he poffeffed hardly a book, and was obliged to ranfack Germany and France for volumes to enable him to fulfil his bargain. Such is the friendfhip, and fuch the gratitude, which fubfift among the amiable pupils of nature, and the philanthropic advocates for the rights of man.

CAVENDISH, a townfhip in Windfor co. Vermont, W. of Weathersfield, on Black river, having 491 inhabitants. Upon this river, and within this townfhip, the channel has been worn down 100 feet, and rocks of very large dimenfions have been undermined and thrown down one upon another. Holes are wrought in the rocks of various dimenfions, and forms; fome cylindrical, from 1 to 8 feet in diameter, and from 1 to 15 feet in depth; others are of a fpherical form from 6 to 20 feet diameter, worn almoft perfectly fmooth, into the folid body of a rock.—*Morse*.

CAUSE has been defined, we think, with accuracy in the Encyclopædia, and the doctrine ftated which we believe to be true. Objections however have been made to that doctrine, of which we have endeavoured to remove fome, under the title ACTION, in this Supplement; and the doctrine itfelf has been well illuftrated (at leaft fuch is our opinion) in the fupplementary article ASTRONOMY. We have, therefore, very little to add here on the fubject of caufes, though it is the moft important fubject which can employ the mind of man. What is the relation between a phyfical caufe and that which is termed its effect—between heat, for inftance, and the fufion of metals? Is it a *neceffary connection*, or only a *conjunction*, difcovered by experience to be *conftant?*

If by *neceffary* connection be meant that kind of connection of which the contrary cannot be conceived, we do not think that the connection of any phyfical caufe with its effect can be called neceffary. We fee no difficulty in conceiving, that fire, inftead of fufing gold, might fix mercury. This *may* indeed be impoffible; and we might perhaps fee the impoffibility, did we as completely know the nature of fire and of metals as we know the relations of pure geometry. We know that the three angles of a plain triangle cannot poffibly be either greater or lefs than two right angles; for in this comparifon nothing is hid from our mental view. We do not, however, perceive the impoffibility of mercury being fixed, as clay is hardened, by heat; for of *heat*, and mercury, and clay, we know very little, and that little is the offspring of experience.

But if the connection between caufe and effect be not *neceffary*, are we not deprived of the means of demonftrating the great fundamental truth of religion? We have nowhere faid, that the connection between caufe and effect is not neceffary; but only, that we do not perceive the neceffary connection between what are called *phyfical* caufes and their effects. That every event is, and muft be, brought about by *fome caufe*, or fome *agency*, we hold to be a felf-evident truth, which no man can deny who underftands the terms in which it is expreffed; but what or where the agency is, we can very feldom, if ever, know, except when we think of our own voluntary actions. When a change is obferved, we cannot doubt of its being produced by fomething: either the thing changed is animated and has produced the change by its own agency, juft as we move our heads and legs by an act of volition; or if it be inanimated, and of itfelf incapable of agency, the change has been produced by fomething external, denominated a *caufe*. But all external caufes, which are not likewife agents, in the proper fenfe of the word, may be traced, we think, as effects up to fome agency; and therefore, in our opinion, there is no real, ultimate, efficient, caufe but mind, or that which is endued with power. In proof of this doctrine, if it need any proof, we can only refer to what has been faid elfewhere on our notions of *power* and of *phyfical caufes*. See *(Encycl.)* METAPHYSICS n° 109, &c.—PHILOSOPHY and PHYSICS *paffim*—and *(Suppl.)* ACTION and ASTRONOMY.

CAYAHAGA, or *Cayuga*, fometimes called the Great river, empties in at the S. bank of lake Erie, 40 miles eaftward of the mouth of Huron; having an Indian town of the fame name on its banks. It is navigable for boats; and its mouth is wide, and deep enough to receive large floops from the lake. Near this are the celebrated rocks which project over the lake. They are feveral miles in length, and rife 40 or 50 feet perpendicular out of the water. Some parts of them confift of feveral ftrata of different colours, lying in a horizontal direction; and fo exactly parallel, that they refemble the work of art. The view from the land is grand, but the water prefents the moft magnificent profpect of this fublime work of nature; it is attended, however,

however, with great danger; for if the leaft ftorm arifes, the force of the furf is fuch that no veffel can efcape being dafhed to pieces againft the rocks. Col. Broadfhead fuffered fhipwreck here in the late war and loft a number of his men, when a ftrong wind arofe, fo that the laft canoe narrowly efcaped. The heathen Indians, when they pafs this impending danger, offer a facrifice of tobacco to the water.

Part of the boundary line between the U. S. A. and the Indians, begins at the mouth of Cayahoga, and runs up the fame to the portage between that and the Tufcarawa branch of the Mufkingum.

The Cayuga nation, confifting of 500 Indians, 40 of whom refide in the United States, the reft in Canada, receive of the ftate of New-York an annuity of 2300 dollars, befides 50 dollars granted to one of their chiefs, as a confideration for lands fold by them to the ftate, and 500 dollars from the United States, agreeably to the treaty of 1794.—*Morse.*

CAYUGA, a beautiful lake in Onondaga co. New-York, from 35 to 40 miles long, about 2 miles wide, in fome places 3, and abounds with falmon, bafs, catfifh, eels, &c. It lies between Seneca and Owafco lake, and at the N. end empties into Scayace River which is the S. eaftern part of Seneca River whofe waters run to lake Ontario. On each fide of the lake is a ferry houfe, where good attendance is given. The refervation lands of the Cayuga Indians lie on both fides of the lake, at its northern end.—*ib.*

CEDAR *Point*, a port of entry in Charles co. Maryland, on the E. fide of Potowmac River, about 12 miles below Port Tobacco, and 96 S. by W. of Baltimore. Its exports are chiefly tobacco and Indian corn, and in 1794, amounted in value to 18,593 dollars.—*ib.*

1 Definition. CENTER, or CENTRE, a word borrowed from the French name *ceintre* or *cintre*, given to the frame of timber by which the brick or ftone of arched vaulting is fupported during its erection and from which it receives its form and curvature.

2 Purpofe of this article. It is not our intention to defcribe the variety of conftructions which may be adopted in eafy fituations, where the arches are of fmall extent, and where fufficient foundation can be had in every part of it for fupporting the frame. In fuch cafes, the frequency of the props which we can fet up difpenfes with much care; and a frame of very flight timbers, connected together in an ordinary way, will fuffice for carrying the weight, and for keeping it in exact fhape. But, when the arches have a wide fpan, and confequently a very great weight, and when we cannot fet up intermediate pillars, either for want of a foundation in the foft bottom of a river, or becaufe the arch is turned between two lofty piers, as in the dome of a ftately cathedral—we are then obliged to reft every thing on the piers themfelves; and the framing which is to fupport our arch before the keyftone is fet, muft itfelf be an arch, depending on the mutual abutment of its beams. One fhould think that this view of the conftruction of a centre would offer itfelf at the firft, naturally derived from the erection it was to affift: but it has not been fo. When intermediate pillars were not employed, it was ufual to frame the mould for the arch with little attention to any thing but its fhape, and then to crofs it and recrofs it in all directions with other pieces of timber, till it was thought fo bound together that it could be lifted in any pofition, and, when loaded with any weight, could not change its fhape. The frame was then raifed in a lump, like any folid body of the fame fhape, and fet in its place. This is the way ftill practifed by many country artifts, who, having no clear principles to guide them, do not ftop till they have made a load of timber almoft equal to the weight which it is to carry.

But this artlefs method, befides leading the employer into great expence, is frequently fatal to the undertaker, from the unfkilfulnefs of the conftruction. The beams which connect its extremities, are made alfo to fupport the middle by means of pofts which reft on them. They are therefore expofed to a tranfverfe or crofs ftrain, which they are not able to bear. Their number muft therefore be increafed, and this increafes the load. Some of thefe crofs ftrains are derived from beams which are preffed very obliquely, and therefore exert a prodigious thruft on their fupports. The beams are alfo greatly weakened by the mortifes which are cut in them to receive the tenons of the croffing beams: and thus the whole is exceedingly weak, in proportion to what the fame quantity of timber may be made by a proper difpofition of its parts.

3 General principles of conftruction. The principles from which we are to derive this difpofition are the general mechanical principles of carpentry, of which we have given fome account in that article. Thefe furnifh one general rule: When we would give the utmoft ftrength poffible to a frame of carpentry, every piece fhould be fo difpofed that it is fubject to no ftrain but what either pufhes or draws it in the direction of its length: and, if we would be indebted to timber alone for the force or ftrength of the centre, we muft reft all on the firft of thefe ftrains; for when the ftraining force tends to *draw* a beam out of its place, it muft be held there by a mortife and tenon, which poffeffes but a very trifling force, or by iron ftraps and bolts. Cafes occur where it may be very difficult to make every ftrain a thruft, and the beft artifts admit of ties; and indeed where we can admit a tie-beam connecting the two feet of our frame, we need feek no better fecurity. But this may fometimes be very inconvenient. When it is the arch of a bridge that we are to fupport, fuch a tie-beam would totally ftop the paffage of fmall craft up and down the river. It would often be in the water, and thus expofed to the moft fatal accidents by frefhes, &c. Interrupted ties, therefore, muft be employed, whofe joint or meetings muft be fupported by fomething analogous to the king-pofts of roofs. When this is judicioufly done, the fecurity is abundantly good. But great judgment is neceffary, and a very fcrupulous attention to the difpofition of the pieces. It is by no means an eafy matter to difcern whether a beam, which makes a part of our centre is in a ftate of compreffion or in a ftate of extenfion. In fome works of the moft eminent carpenters even of this day, we fee pieces confidered as ftruts (and confiderable dependence had on them in this capacity), while they are certainly performing the office of tie-beams, and fhould be fecured accordingly. This was the cafe in the boldeft centre (we think) that has been executed in Europe, that of the bridge of Orleans, by Mr Hupeau. Yet it is evidently of great confequence not to be miftaken in this point; for when we are miftaken, and the piece is ftretched which we imagine to be compreffed, we not only are deprived of fome

fupport

Center. support that we expected, but the expected support has become an additional load.

4 How to distinguish a strut from a tie.

To ascertain this point, we may suppose the piers to yield a little to the pressure of the archstones on the centre frames. The feet, therefore, fly outwards, and the shape is altered by the sinking of the crown. We must draw our frame anew for this new state of things, and must notice what pieces must be made longer than before. All such pieces have been acting the part of tie beams.

But a centre has still another office to sustain; it must keep the arch in its form; that is, while the load on the centre is continually increasing, as the masons lay on more courses of arch-stones, the frame must not yield and go out of shape, sinking under the weight on the haunches, and rising in the crown, which is not yet carrying any load. The frame must not be supple; and must derive its stiffness, not from the closeness and strength of its joints, which are quite insignificant when set in competition with such immense strains, but from struts or ties, properly disposed, which hinder any of the angles from changing its amplitude.

5 How to secure stiffness and strength.

It is obvious, from all that has been said, that the strength and stiffness of the whole must be found in the triangles into which this frame of carpentry may be resolved. We have seen that the strains which one piece produces on two others, with which it meets in one point, depends on the angles of their intersection; and that it is greater as an obtuse angle is more obtuse, or an acute angle more acute. And this suggests to us the general maxim, "to avoid as much as possible all very obtuse angles." Acute angles, which are not necessarily accompanied by obtuse ones, are not so hurtful; because the strain here can never exceed the straining force; whereas, in the case of an obtuse angle, it may surpass it in any degree.

Such are the general rules on this subject. Although something of the mutual abutment of timbers, and the support derived from it, has been long perceived, and employed by the carpenters in roofing, and also (doubtless) in the forming of centres, yet it is a matter of historical fact, that no general and distinct views had been taken of it till about the beginning of this century, or a little earlier. Fontana has preserved the figure of the frames on which the arches of St Peter's at Rome were turned. The one employed for the dome is constructed with very little skill; and those for the arches of the nave and transepts, though incomparably superior, and of considerable simplicity and strength, are yet far inferior to others which have been employed in later times. It is much to be regretted that no trace remains of the forms employed by the great architect and consummate mechanician Sir Christopher Wren. We should doubtless have seen in them every thing that science and great sagacity could suggest. We are told, indeed, that his centering for the dome of St Paul's was a wonder of its kind; begun in the air at the height of 160 feet from the ground, and without making use of even a projecting corniche whereon to rest it.

6 The earliest theory, on scientific principles,

The earliest theory of the kind that we have met with, that is proposed on scientific principles, and with the express purpose of serving as a lesson, are two centres by Mr Pitot of the Academy of Sciences, about the beginning of this century. As they have considerable merit (greatly resembling those employed by Michael Angelo in the nave of St Peter's), and afford some good maxims, we shall give a short account of them. We crave the excuse of the artists if we should employ their terms of art somewhat aukwardly, not being very familiarly acquainted with them. Indeed, we observe very great differences, and even ambiguity, in the terms employed.

What we shall describe under the name of a *centre* is (properly speaking) only one frame, truss, or rib, of a centre. They are set up in vertical planes, parallel to each other, at the distance of 5, 6, 7, or 8 feet, like the trusses or main couples of a roof. Bridging joists are laid across them.—In smaller works these are laid sparingly, but of considerable scantling, and are boarded over; but for great arches, a bridging joist is laid for every course of archstones, with blockings between to keep them at their proper distances. The stones are not laid immediately on these joists, but beams of soft wood are laid along each joist, on which the stone is laid. These beams are afterwards cut out with the chissel, in order to separate the centre from the ring of stones, which must now support each other by their mutual abutment.

The centre is distinguishable into two parts, ALLB (fig. 1.) and LDL, which are pretty independent of each other, or at least act separately. The horizontal STRETCHER LL cuts the semicircle ADB half way between the spring and the crown of the arch; the arches AL,LD, being 45° each. This stretcher is divided in the same proportion in the points G and H; that is, GH is one half of LL, and LG, HL are each one-fourth of LL nearly. Each end is supported by two STRUTS EI, GI, which rest below on a SOLE OR BED properly supported. The interval between the heads of the struts GI, HK is filled up by the STRAINING BEAM GH, abutting in a proper manner on the struts (see CARPENTRY, *Supplement*). The extremities L, L, are united in like manner by butting joints, with the heads of the outer struts. The ARCH MOULDS AP, BP, are connected with the struts by cross pieces PQ, which we shall call BRIDLES, which come inwards on each side of the struts (being double), and are bolted to them. This may be called the lower part of the frame. The upper part consists of the king post DR, supported on each side by the two struts or braces ML, ON, mortised into the post, and also mortised into the stretcher, at the points L, N, where it is supported by the struts below. The arches LD, LD are connected with the struts by the bridles PQ, in the same manner as below. 7 Illustrated Plate XIV.

8 Propriety of this arrangement.

There is a great propriety in many parts of this arrangement. The lower parts or haunches of the arch press very lightly on the centres. Each archstone is lying on an inclined plane, and tends to slide down only with its relative weight; that is, its weight is to its tendency to slide down the joint as radius to the sine of elevation of the joint. Now it is only by this tendency to slide down the joint that they press on the centering, which in every part of the arch is perpendicular to the joint: But the pressure on the joint, arising from this cause, is much less than this, by reason of the friction of the joints. A block of dry freestone will not slide down at all; and therefore will not press on the centering, if the joint be not elevated 35 degrees at least. But the archstones are not laid in this manner, by sliding them down along the joint, but are laid on the centres, and slide

ſlide down *their* ſlope, till they touch the blocks on which they are to reſt; ſo that, in laying the archſtones, we are by no means allowed to make the great deduction from their weight juſt now mentioned, and which Mr Couplet preſcribes (Mem. Acad. Sciences, 1729). But there is another cauſe which diminiſhes the preſſure on the centres; each block ſlides down the planks on which it is laid, and preſſes on the block below it, in the direction of the tangent to the arch. This preſſure is tranſmitted through this block, in the ſame direction, to the next, and through it to the third, &c. In this manner it is plain that, as the arch advances, there is a tangential preſſure on the lower archſtones, which diminiſhes their preſſure on the frame, and, if ſufficiently great, might even puſh them away from it. Mr Couplet has given an analyſis of this preſſure, and ſhews, that in a ſemicircular arch of uniform thickneſs none of the arch ſtones below 30° preſs on the frames. But he (without ſaying ſo) calculates on the ſuppoſition that the blocks deſcend along the circumference of this frame in the ſame manner as if it were perfectly ſmooth. As this is far from being the caſe, and as the obſtructions are to the laſt degree various and irregular, it is quite uſeleſs to inſtitute any calculation on the ſubject. A little reflection will convince the reader, that in this caſe the obſtruction ariſing from friction *muſt* be taken into account, and that it *muſt not* be taken into account in eſtimating the preſſure of each ſucceſſive courſe of ſtones as they are laid. It is enough that we ſee that the preſſure of the lower courſes of archſtones on the frame is diminiſhed. Mr Couplet ſays, that the whole preſſure of a ſemicircular arch is but $\frac{4}{5}$ths of its weight; but it is much greater, for the reaſon juſt now given. We have tried, with a well-made wooden model (of which the circumference was rubbed with black lead to render it more ſlippery), whether *any* part of the wooden blocks repreſenting the archſtones were detached from the frame by the tangential preſſure of the ſuperior blocks; but we could not ſay confidently that any were ſo detached. We perceived that all kept hold of a thin ſlip of Chineſe paper (alſo rubbed with black lead) between them and the frame, ſo that a ſenſible force was required to pull it out. From a combination of circumſtances, which would be tedious to relate, we believe that the centres carry more than two-thirds of the weight of the arch before the keyſtone is ſet. In elliptical and lower pitched circular arches, the proportion is ſtill greater.

9 By a centre of M. Pitot's.

It ſeems reaſonable enough, therefore, to diſpoſe the framing in the manner propoſed by Pitot, directing the main ſupport to the upper maſs of the arch, which preſſes moſt on the frame. We ſhall derive another advantage from this conſtruction, which has not occurred to Mr Pitot.

There is an evident propriety in the manner in which he has diſtributed the ſupports of the upper part. The ſtruts which carry the king poſt ſpring from thoſe points of the ſtretcher where it reſts on the ſtruts below: thus the ſtretcher, on which all depends, bears no tranſverſe ſtrains. It is ſtretched by the ſtrut above it, and it is compreſſed in a ſmall degree between the ſtruts below it, at leaſt by the outer ones. Mr Pitot propoſes the ſtraining beam GH as a lateral ſupport to the ſtretcher, which may therefore be of two pieces: but although it *does* augment its ſtrength, it does not ſeem neceſſary for it. The ſtretcher is abundantly carried by the ſtrap, which may and ſhould ſuſpend it from the king poſt. The great uſe of the ſtraining piece is to give a firm abutment to the inner ſtruts, without allowing any lateral ſtrain on the ſtretcher. *N. B.* Great care muſt be taken to make the hold ſufficiently firm and extenſive between the ſtretcher and the upper ſtruts, ſo that its coheſion to reſiſt the thruſts from theſe ſtruts may be much employed.

The only imperfection that we find in this frame is the lateral ſtrains which are brought upon the upper ſtruts by the bridles, which certainly tranſmit to them part of the weight of the archſtones on the curves. The ſpace between the curves and ML ſhould alſo have been truſſed. Mr Pitot's form is, however, extremely ſtiff; and the cauſing the middle bridle to reach down to the ſtretcher, ſeems to ſecure the upper ſtruts from all riſk of bending.

This centre gives a very diſtinct view of the offices of all the parts, and makes therefore a proper introduction to the general ſubject. It is the ſimpleſt that can be in its principle, becauſe all the eſſential parts are ſubjected to one kind of ſtrain. The ſtretcher LL is the only exception, and its extenſion is rather a collateral circumſtance than a ſtep in the general ſupport.

10 The ſtrength of this frame

The examination of the ſtrength of the frame is extremely eaſy. Mr Pitot gives it for an arch of 60 feet ſpan, and ſuppoſes the archſtones 7 feet long, which is a monſtrous thickneſs for ſo ſmall an arch; 4 feet is an abundant allowance, but we ſhall abide by his conſtruction. He gives the following ſcantlings of the parts:

The ring or circumference conſiſts of pieces of oak 12 inches broad and 6 thick.

The ſtretcher LL is 12 inches ſquare.

The ſtraining piece GH is alſo 12 by 12.

The lower ſtruts 10 by 8.

The king poſt 12 by 12.

The upper ſtruts 10 by 6.

The bridles 20 by 8.

Theſe dimenſions are French, which is about $\frac{1}{17}$th larger than ours, and the ſuperficial dimenſions (by which the ſection and the abſolute ſtrength is meaſured) is almoſt $\frac{1}{8}$th larger than ours. The cubic foot, by which the ſtones are meaſured, exceeds ours nearly $\frac{1}{5}$th. The pound is deficient about $\frac{1}{13}$th. But ſince very nice calculation is neither eaſy nor neceſſary on this ſubject, it is needleſs to depart from the French meaſures, which would occaſion many fractional parts and a troubleſome reduction.

The arch is ſuppoſed to be built of ſtone which weighed 160 pounds per foot. Mr Pitot, by a computation (in which he has committed a miſtake), ſays, that only $\frac{11}{14}$ths of this weight is carried by the frame. We believe, however, that this is nearer the truth than Mr Couplet's aſſumption of $\frac{4}{5}$ths already mentioned.

Mr Pitot farther aſſumes, that a ſquare inch of ſound oak will carry 8640 pounds. By his language we ſhould imagine that it will not carry much more: but this is very far below the ſtrength of any Britiſh oak that we have tried; ſo far, indeed, that we rather imagine that he means that this load may be laid on it with perfect ſecurity for any time. But to compenſate for knots and other accidental imperfections, he aſſumes 7200 as the meaſure of its abſolute force.

He

Center.

He computes the load on each frame to be 707520 pounds, which he reduces to $\frac{11}{14}$ths, or 555908 pounds.

The abſolute force of each of the lower ſtruts is 576000 (at 7200 per inch), and that of the curves 518400. Mr Pitot, conſidering that the curves are kept from bending outwards by the arch ſtones which preſs on them, thinks that they may be conſidered as acting preciſely as the outer ſtruts EI. We have no objection to this ſuppoſition.

11 Computed.

With theſe data we may compute the load which the lower truſs can ſafely bear by the rule delivered in the article CARPENTRY. We therefore proceed as follows:

Meaſure off by a ſcale of equal parts $a\,s$, $a\,t$, each 576000, and add $t\,v$ 518400. Complete the parallelogram $a\,v\,x\,s$, and draw the vertical $x\,c$, meeting the horizontal line a C in c. Make $c\,b$ equal to $c\,a$. Join $x\,b$, and complete the parallelogram $a\,x\,b\,y$. It is evident that the diagonal $x\,y$ will repreſent the load which theſe pieces can carry; for the line $a\,v$ is the united force of the curve AP and the ſtrut IE, and $a\,s$ is the ſtrength of IG. Theſe two are equivalent to $a\,x$. $x\,b$ is, in like manner, equivalent to the ſupport on the other ſide, and $x\,y$ is the load which will juſt balance the two ſupports $a\,x$ and $b\,x$.

When $x\,y$ is meaſured on the ſame ſcale, it will be found = 2850000 pounds. This is more than five times the load which actually lies on the frame. It is therefore vaſtly ſtronger than is neceſſary. Half of each of the linear dimenſions would have been quite ſufficient, and the ſtruts needed only to be 5 inches by 4. Even this would have carried twice the weight, and would have borne the load really laid on it with perfect ſafety.

We proceed to meaſure the ſtrength of the upper part. The force of each ſtrut is 432000, and that of the curve is 518400; therefore, having drawn M v parallel to the ſtrut ON, make M v = 432000, and M s = 432000 + 518400. Complete the parallelogram M $s\,r\,v$. Draw the horizontal line $r\,k$, cutting the vertical MC in k, and make $k\,y$ = M k. It is plain, from what was done for the lower part, that M y will meaſure the load which can be carried by the upper part. This will be found = 1160000. This is alſo greatly ſuperior to the load; but not in ſo great a proportion as the other part. The chief part of the load lies on the upper part; but the chief reaſon of the difference is the greater obliquity of the upper ſtruts. This ſhortens the diagonal M y of the parallelogram of forces. Mr Pitot ſhould have adverted to this; and inſtead of making the upper ſtruts more ſlender than the lower, he ſhould have made them ſtouter.

The ſtrain on the ſtretcher LL is not calculated. It is meaſured by $r'\,k'$, when M y is the load actually lying on the upper part. Leſs than the ſixth part of the coheſion of the ſtretcher is more than ſufficient for the horizontal thruſt; and there is no difficulty of making the foot joints of the ſtruts abundantly ſtrong for the purpoſe.

The reader will perceive that the computation juſt now given does not ſtate the proportions of the ſtrains *actually exerted* on the different pieces, but the load on the whole, on the ſuppoſition that each piece is ſubjected to a ſtrain proportioned to its ſtrength. The other calculation is much more complicated, but is not neceſſary here.

Center.

This centre has a very palpable defect. If the piers ſhould yield to the load, and the feet of the centre fly out, the lower part will exert a very conſiderable ſtrain on the ſtretcher, tending to break it acroſs between N and L, and on the other ſide. HKF of the lower part is firmly bound together, and cannot change its ſhape, and will therefore act like a lever, turning round the point F. It will draw the ſtrut HK away from its abutment with GH, and the ſtretcher will be ſtrained acroſs at the place between H and F, where it is bolted with the bridle. This may be reſiſted in ſome degree by an iron ſtrap uniting ON and HK; but there will ſtill be a want of proportional ſtrength. Indeed, in an arch of ſuch height (a ſemicircle), there is but little riſk of this yielding of the piers; but it is an imperfection.

12 A centre on the ſame principles for an elliptical arch.

The centre (fig. 2.) is conſtructed on the ſame principle preciſely for an elliptical arch (A). The calculation of its ſtrength is nearly the ſame alſo; only the two upper ſtruts of a ſide being parallel, the parallelogram M $s\,r\,v$ (of fig. 1.) is not needed, and in its ſtead we meaſure off on ON a line to repreſent twice its ſtrength. This comes in place of M r' of fig. 1.—*N. B.* The calculation proceeds on the ſuppoſition that the ſhort ſtraining piece MM makes but one firm body with the king poſt. Mr Pitot employed this piece (we preſume) to ſeparate the heads of the ſtruts, that their obliquity might be leſſened thereby: and this is a good thought; for when the angle formed by the ſtruts on each ſide is very open, the ſtrain on them becomes very great.

The ſtretcher of this frame is ſcarfed in the middle. Suppoſe this joint to yield a little, there is a danger of the lower ſtrut ON loſing its hold, and ceaſing to join in the ſupport; for when the crown ſinks by the lengthening of the ſtretcher, the triangle ORN of fig. 2. will be more diſtorted than the ſpace above it, and ON will be looſened. But this will not be the caſe when the ſinking of the crown ariſes from the mere compreſſion of the ſtruts. Nor will it happen at all in the centre, fig. 1. On the contrary, the ſtrut ON will abut more firmly by the yielding of the foot of ML.

The figure of this arch of Mr Pitot's conſiſts of three arches of circles, each of 60 degrees. As it is elegant, it will not be unacceptable to the artiſt to have a conſtruction for this purpoſe.

13 How to conſtruct ſuch an arch.

Make BY = CD, and CZ = $\frac{1}{2}$ CY. Deſcribe the ſemicircle ZÆY, and make ZS = ZÆ. S is the centre of the ſide arches, each of 60 degrees. The centre T of the arch, which unites theſe two, is at the angle of an equilateral triangle STS.

This conſtruction of Mr Pitot's makes a handſome oval, and very near an ellipſis, but lies a little without it. We ſhall add another of our own, which coincides with the ellipſe in eight points, and furniſhes the artiſt, by

(A) It is the middle arch of the bridge at Liſle Adam, of which Mr Pitot had the direction. It is of 80 feet ſpan, and riſes 31 feet.

Center. by the way, a rule for drawing an infinite variety of ovals.

Let AB, DE (fig. 2. N° 2.) be the axes of an ellipse, C the centre, and F, *f* the two foci. Make C *b* = CD, and describe a circle A D *b e* passing through the three given points A, D, and *b*. It may be demonstrated, that if from any point P of the arch AD be drawn a chord PD, and if a line P R *r* be drawn, making the angle DPR=PDC, and meeting the two axes in the points R and *r*, then R and *r* will be the centres of circles, which will form a quarter APD of an oval, which has AB and DE for its two axes.

We want an oval which shall coincide as much as possible with an ellipsis? The most likely method for this is to find the very point P where the ellipsis cuts the circle AD *b e*. The easiest way for the artist is to describe an arch of a circle *a m*, having AB for its radius, and the remote focus *f* for its centre. Then set one foot of the compasses on any point P, and try whether the distance PF from the nearest focus F is exactly equal to its distance P *m* from that circle. Shifting the foot of the compasses from one point of the arch to another, will soon discover the point. This being found, draw PD, make the angle DP *r* = PD *r*, and R and *r* are the centres wanted. Then make C *s* = CR, and we get the centres for the other side.

The geometer will not relish this mechanical construction. He may therefore proceed as follows: Draw D *d* parallel to AB, cutting the circle in *d*. Draw *e d*, cutting AC in N. Draw CG parallel to A *e*, and make the angle CG *i* = AD *e*. Bisect CN in O, and join O *i*. Make OM, OM′= O *i*, and draw MP, M′P′ perpendicular to AB. These ordinates will cut the circle AD *b e* in the points P and P′, where it is cut by the ellipse. We leave the demonstration as a geometrical exercise for the dilettante.

14 Centre for the nave of St Peter's.

We said, that this centering of Mr Pitot's resembled in principle the one employed by Michael Angelo for the nave and transepts of St Peter's church at Rome. Fontana, who has preserved this, ascribes the construction of it to one of the name of San Gallo. A sketch of it is given in fig. 3. It is, however, so much superior, and so different in principle, from that employed for the cupola, that we cannot think it the invention of the same person. It is, like Pitot's, not only divisible, but really divided into two parts, of which the upper carries by much the greatest part of the load. The pieces are judiciously disposed, and every important beam is amply secured against all transverse strains. Its only fault is a great profusion of strength. The innermost polygon *a g h b* is quite superfluous, because no strain can force in the struts which rest on the angles. Should the piers yield outwards, this polygon will be loose, and can do no service. Nor is the triangle *g i h* of any use, if the king post above it be strapped to the tie-beam and straining sill. Perhaps the inventor considered the king post as a pillar, and wished to secure the tie-beam against its cross strain. This centering, however, must be allowed to be very well composed; and we expect that the well-informed reader will join us in preferring it to Mr Pitot's, both for simplicity of principle, for scientific propriety, and for strength.

There is one considerable advantage which may be derived from the actual division of the truss into two parts. If the tie-beam LL, instead of resting on the stretcher EF, had rested on a row of chocks formed like double wedges, placed above each other, head to point, the upper part of the centering might be struck independent of the lower, and this might be done gradually, beginning at the outer ends of the stretcher. By this procedure, the joints of the archstones will close on the haunches, and will almost relieve the lower centering, so that all can be pulled out together. Thus may the arch settle and consolidate in perfect safety, without any chance of breaking the bond of the mortar in any part; an accident which frequently happens in great arches. This procedure is peculiarly advisable for low pitched or elliptical arches. But this will be more clearly seen afterwards, when we treat of the internal movements of an arch of masonry.

This may suffice for an account of the more simple construction of trussed centres; and we proceed to such as have a much greater complication of principle. We shall take for examples some constructed by Mr Perronet, a very celebrated French architect.

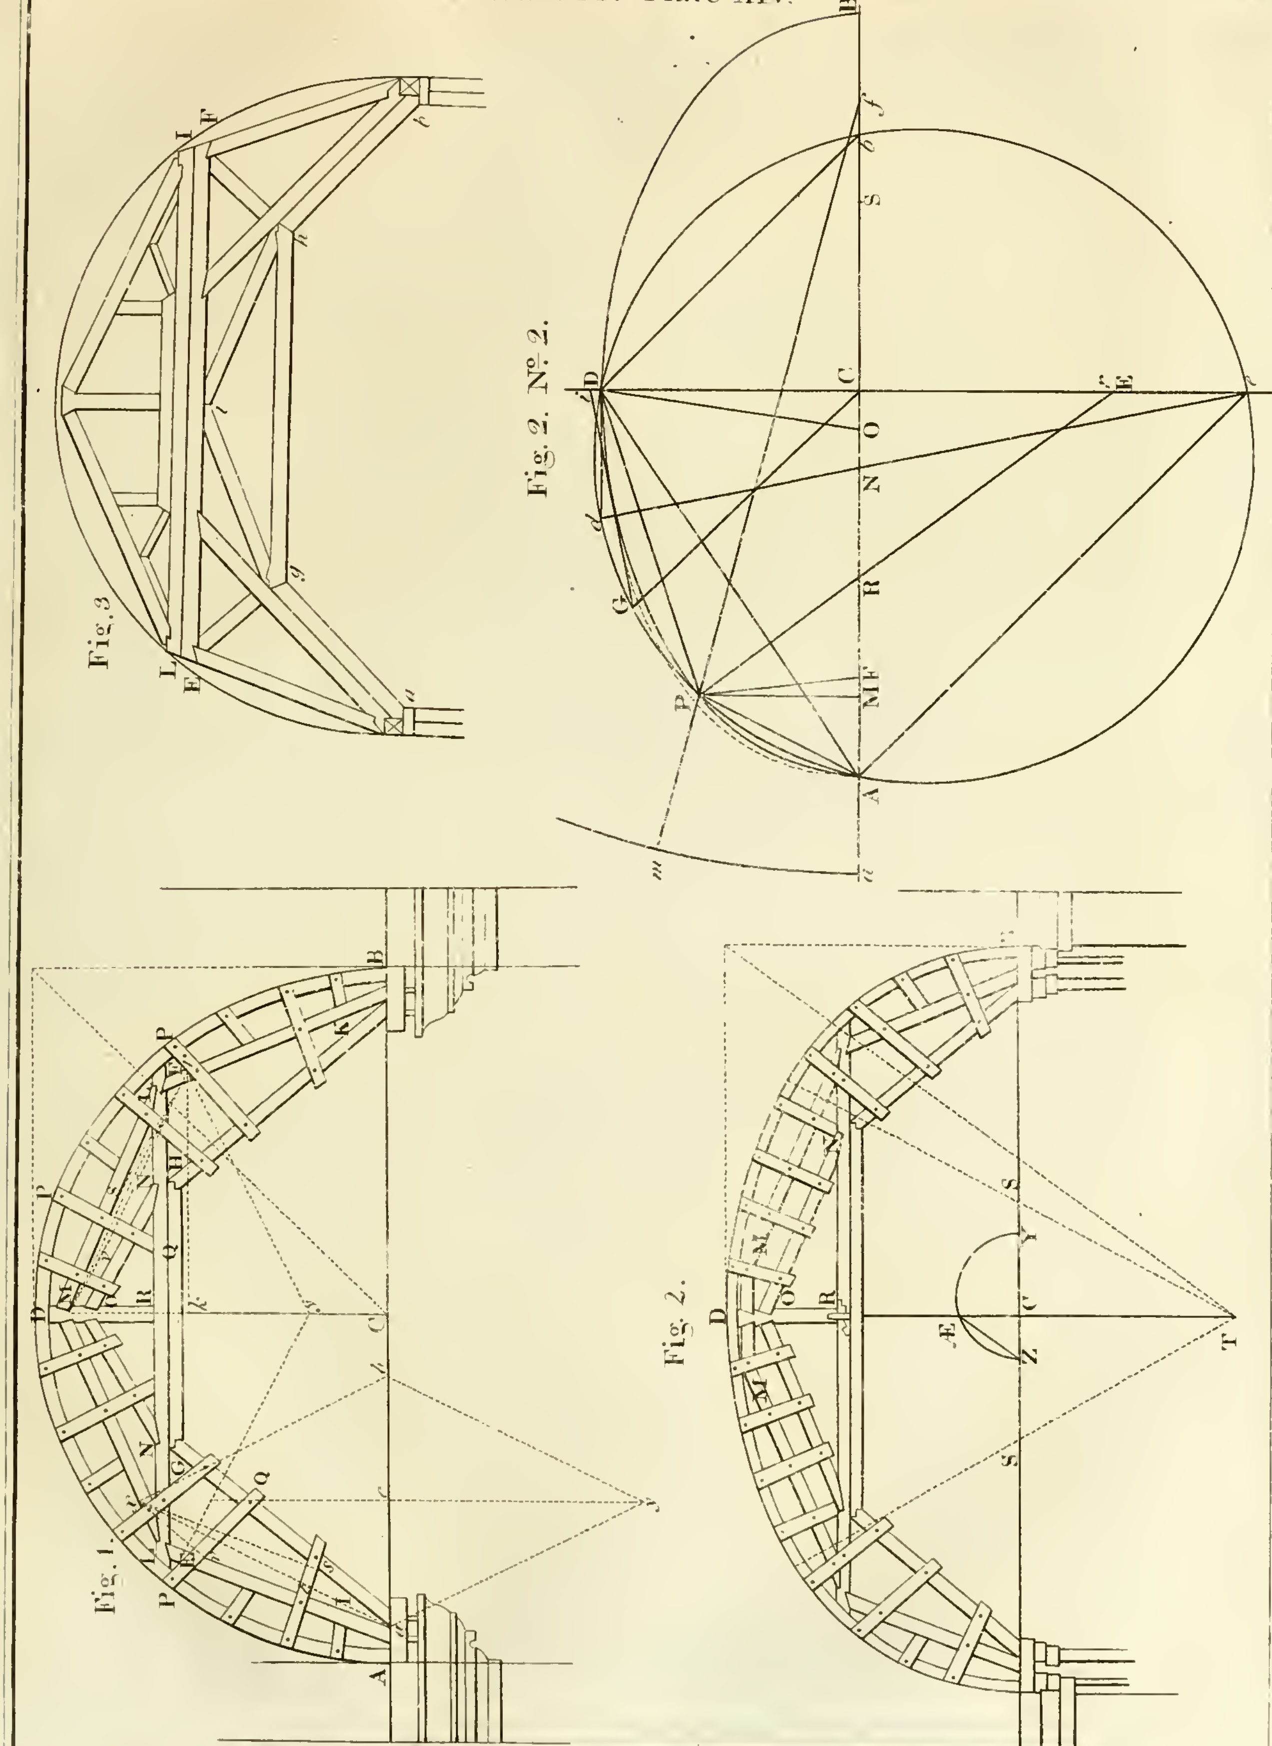
15 Perronet's maxim of construction.

Mr Perronet's general maxim of construction is to make the truss consist of several courses of separate trusses, independent (as he thinks) of each other, and thus to employ the joint support of them all. In this construction it is not intended to make use of one truss, or part of one truss, to support another, as in the former set, and as is practised in the roofs of St Paul's church, Covent Garden, and in Drury Lane theatre. Each truss spans over the whole distance of the piers, and would stand alone (having, however, a tottering equilibrium). It consists of a number of struts, set end to end, and forming a polygon. These trusses are so arranged, that the angles of one are in the middle of the sides of the next, as when a polygon is inscribed in a circle, and another (of the same number of sides) is circumscribed by lines which touch the circle in the angles of the inscribed polygon. By this construction the angles of the alternate trusses lie in lines pointing towards the centre of the curve. King posts are therefore placed in this direction between the adjoining beams of the trusses. These king posts consist of two beams, one on each side of the truss, and embrace the truss-beams between them, meeting in the middle of their thickness. The abutting beams are mortised, half into each half of the post. The other beam which makes the base of the triangle, passes through the post, and a strong bolt is driven through the joint, and secured by a key or a nut. In this manner is the whole united; and it is expected, that when the load is laid on the uppermost truss, it will all butt together, forcing down the king posts, and therefore pressing them on the beams of all the inferior trusses, causing them also to abutt on each other, and thus bear a share of the load. Mr Perronet does not assume the invention to himself; but says, that it was invented and practised by Mr Mansard de Sagonne at the great bridge of Moulins. It is much more ancient, and is the work of the celebrated physician and architect Perrault; as may be seen in the collection of machines and inventions of that gentleman published after his death, and also in the great collection of inventions approved of by the Academy of Sciences. It is this which we propose to examine.

16 Centering employed for the bridge of Cravant.

Fig. 4. represents the centering employed for the bridge of Cravant. The arches are elliptical, of 60 feet span and 20 feet rise. The archstones are four feet thick,

CENTRES. Plate XIV.



Center. thick, and weigh 176 pounds per foot. The truſs-beams were from 15 to 18 feet long, and their ſection was 9 inches by 8. Each half of the king poſts was about 7 feet long, and its ſection 9 inches by 8. The whole was of oak. The five truſſes were $5\frac{1}{2}$ feet aſunder. The whole weight of the arch was 1350000 lbs. which we may call 600 tons (it is 558). This is about 112 tons for each truſs. We muſt allow near 90 tons of this really to preſs the truſs. A great part of this preſſure is borne by the four beams which make the feet of the truſs, coupled in pairs on each ſide. The diagonal of the parallelogram of forces drawn for theſe beams is, to one of the ſides, in the proportion of 360 to 285. Therefore ſay, as 360 to 285; ſo is 90 to $71\frac{1}{4}$ tons, the thruſt on each foot. The ſection of each is 144 inches. We may with the utmoſt ſafety lay three tons on every inch for ever. This amounts to 432 tons, which is more than ſix times the ſtrain really preſſing the foot beams in the direction of their length; nay, the upper truſs alone is able to carry much more than its load. The abſolute ſtrength of its foot-beam is 216 tons. It is much more advantageouſly placed; for the diagonal of the parallelogram of forces correſponding to its poſition is to the ſide as 438 to 285. This gives $58\frac{6}{10}$ tons for the ſtrain on each foot; which is not much above the fourth part of what it is able to carry for ever. No doubt can therefore be entertained of the ſuperabundant ſtrength of this centering. We ſee that the upper row of ſtruts is quite ſufficient, and all that is wanted is to procure ſtiffneſs for it; for it muſt be carefully kept in mind, that this upper row is not like an equilibrated arch. It will be very unequally loaded as the work advances. The haunches of the frame will be preſſed down, and the joints at the crown raiſed up. This muſt be reſiſted.

Here then we may gather, by the way, a uſeful leſſon. Let the outer row of ſtruts be appropriated to the carriage of the load, and let the reſt be employed for giving ſtiffneſs. For this purpoſe let the outer row have abundant ſtrength. The advantages of this method are conſiderable. The poſition of the beams of the exterior row is more advantageous, when (as in this example) the whole is made to reſt on a narrow foot: for this obliges us to make the laſt angle, at leaſt of the lower row, more open, which increaſes the ſtrain on the ſtrut; beſides, it is next to impoſſible to diſtribute the compreſſing thruſts among the different rows of the truſs-beams; and a beam which, during one period of the maſon work, is acting the part of a ſtrut, in another period is bearing no ſtrain but its own weight, and in another it is ſtretched as a tie. A third advantage is, that, in a caſe like this, where all reſts on a narrow foot, and the lower row of beams are bearing a great part of the thruſt, the horizontal thruſt on the pier is very great, and may puſh it aſide. This is the moſt ruinous accident that can happen. An inch or two of yielding will cauſe the crown of the arch to ſink prodigiouſly, and will inſtantly derange all the bearings of the abutting beams: but when the lower beams already act as ties, and are quite adequate to their office, we render the frame perfectly ſtiff or unchangeable in its form, and take away the horizontal thruſt from the piers *entirely*. This advantage is the more valuable, becauſe the very circumſtance which obliges us to reſt all on a narrow foot, places this foot on the very top of the pier, and makes the horizontal thruſt the more dangerous.

But, to proceed in our examination of the centering of Cravant bridge, let us ſuppoſe, that the king poſts are removed, and that the beams are joined by compaſs joints. If the pier ſhall yield in the ſmalleſt degree, both rows of ſtruts muſt ſink; and ſince the angles (at leaſt the outermoſt) of the lower row are more open than thoſe of the upper row, the crown of the lower row will ſink more than that of the upper.

The angles of the alternate rows muſt therefore ſeparate a little. Now reſtore the king poſts; they prevent this ſeparation. Therefore *they are ſtretched*; therefore the beams of the lower row are alſo ſtretched; conſequently they no longer butt on their mortiſes, and muſt be held in their places by bolts. Thus it appears that, in this kind of ſagging, the original diſtribution of the load among the different rows of beams is changed, and the upper row becomes loaded beyond our expectation.

If the ſagging of the whole truſs proceed only from the compreſſion of the timbers, the caſe is different, and we *may* preſerve the original diſtribution of mutual abutment more accurately. But in this caſe the ſtiffneſs of the frame ariſes chiefly from croſs ſtrains. Suppoſe that the frame is loaded with archſtones on each ſide up to the poſts HC, *hc*; the angles E and *e* are preſſed down, and the beams EOF, *eo* F puſh up the point F. This cannot riſe without bending the beams EOF, *eo* F; becauſe O and *o* are held down by the double king poſts, which graſp the beams between them. There is therefore a croſs ſtrain on the beams. Obſerve alſo, that the triangle EHF does not preſerve its ſhape by the connection of its joints; for although the ſtrut beams are mortiſed into the king poſt, they are in very ſhallow mortiſes, rather for ſteadying them than for holding them together. Mr Perronet did not even pin them, thinking that their abutment was very great. The triangle is kept in ſhape by the baſe EF, which is firmly bolted into the middle poſt at O. Had theſe interſections not been ſtrongly bolted, we imagine that the centres of ſome of Mr Perronet's bridges would have yielded much more than they did; yet ſome of them yielded to a degree that our artiſts would have thought very dangerous. Mr Perronet was obliged to load the crown of the centering with very great weights, increaſing them as the work advanced, to prevent the frames from going out of ſhape: in one arch of 120 feet he laid on 45 tons. Notwithſtanding this imperfection, which is perhaps unavoidable, this mode of framing is undoubtedly very judicious, and perhaps the beſt which can be employed without depending on iron work.

17 For the bridge of Nogent.

Fig. 5. repreſents another, conſtructed by Perronet for an arch of 90 feet ſpan and 28 feet riſe. The truſſes were 7 feet apart, and the arch was $4\frac{1}{2}$ thick; ſo that the unreduced load on each frame was very nearly 235 tons. The ſcantling of the ſtruts was 15 by 12 inches. The principle is the ſame as that of the former. The chief difference is, that in this centre the outer truſs-beam of the lower row is not coupled with the middle row, but kept nearly parallel to the outer beam of the upper row. This adds greatly to the ſtrength of the foot, and takes off much of the horizontal thruſt from the pier.

Mr Perronet has ſhewn great judgment in cauſing the polygon of the inner row of truſs-beams gradually to approach the polygon of the outer row. By this

 diſpoſition,

Center. difpofition, the angles of the inner polygon are more acute than thofe of the outer. A little attention will fhew, that the general fagging of all the polygons will keep the abutments of the lower one nearer, or exactly, to their original quantity. We muft indeed except the foot-beam. It is ftill too oblique; and, inftead of converging to the foot of the upper row, it fhould have diverged from it. Had this been done, this centre is almoft perfect in its kind. As it is, it is at leaft fix times ftronger than was abfolutely neceffary. We fhall have occafion to refer to this figure on another occafion.

18 St Maxence. This maxim is better exemplified by Mr Perronet in the centering of the bridge of St Maxence, exhibited in fig. 5. n° 2. than in that of Nogent, fig. 5. n° 1. But we think that a horizontal trufs-beam *a b* fhould have been inferted (in a fubordinate manner) between the king pofts next the crown on each fide. This would prevent the crown from rifing while the haunches only are loaded, without impairing the fine abutments of *c d*, *c d*, when the arch is nearly completed. This is an excellent centering, but is not likely to be of much ufe in thefe kingdoms; becaufe the arch itfelf will be confidered as ungraceful and ugly, looking like a huge lintel. Perronet fays, that he preferred it to the ellipfe, becaufe it was lighter on the piers, which were thin. But the failure of one arch muft be immediately followed by the ruin of all. We know much better methods of lightening the piers.

19 Neuilly, and Fig. 6. reprefents the centering of the bridge of Neuilly, near Paris, alfo by Perronet. The arch has 120 feet fpan, and 30 feet rife, and is 5 feet thick. The frames are 6 feet apart, and each carries an abfolute (that is, not reduced to $\frac{11}{17}$ or to $\frac{4}{7}$) load of 350 tons. The ftrut beams are 17 by 14 inches in fcantling. The king pofts are of 15 by 9 each half; and the horizontal bridles which bind the different frames together in five places, are alfo 15 by 9 each half. There are eight other horizontal binders of 9 inches fquare.

This is one of the moft remarkable arches in the world; not altogether on account of its width (for there are feveral much wider), but for the flatnefs at the crown; for about 26 feet on each fide of the middle it was intended to be a portion of a circle of 150 feet radius. An arch (femicircular) of 300 feet fpan might therefore be eafily conftructed, and would be much ftronger than this, becaufe its horizontal thruft at the crown would be vaftly greater, and would keep it more firmly united.

The bolts of this centre are differently placed from thofe of the former; and the change is judicious. Mr Perronet had doubtlefs found by this time, that the ftiffnefs of his framing depended on the tranfverfe ftrength of the beams; and therefore he was careful not to weaken them by the bolts. But notwithftanding all his care, the framing funk upwards of 13 inches before the keyftones were laid; and during the progrefs of the work, the crown rofe and funk, by various fteps, as the loading was extended along it. When 20 courfes were laid on each fide, and about 16 tons laid on the crown of each frame, it funk about an inch. When 46 courfes were laid, and the crown loaded with 50 tons, it funk about half an inch more. It continued finking as the work advanced; and when the keyftone was fet it had funk 13¼ inches. But this finking was not general; on the contrary the frame had rifen greatly at the very haunches, fo as to open the upper part of the joints, many of which gaped an inch; and this opening of the joints gradually extended from the haunches towards the crown, in the neighbourhood of which they opened on the under fide. This evidently arofe from a want of ftiffnefs in the frame. But thefe joints clofed again when the centres were ftruck, as will be mentioned afterwards.

We have taken particular notice of the movements and twifting of this centre, becaufe we think that they indicate a deficiency, not only of ftiffnefs, but of abutment among the trufs beams. The whole has been too flexible, becaufe the angles are too obtufe: This arifes from their multiplicity. When the intercepted arches have fo little curvature, the power of the load to prefs it inward increafes very faft. When the intercepted arch is reduced to one half, this power is more than doubled; and it is alfo doubled when the radius of curvature is doubled. The king-pofts fhould have been further apart near the crown, fo that the quantity of arch between them fhould compenfate for its diminifhed curvature.

The power of withftanding any given ineqnality of load would therefore have been greater, had the centre confifted of fewer pieces, and their angles of meeting been proportionally more acute. The greateft improvement would have been, to place the foot of the lower tier of trufs-beams on the very foot of the pier, and to have alfo feparated it at the head from the reft with a longer king-poft, and thus to have made the diftances of the beams on the king-pofts increafe gradually from the crown to the fpring. This would have made all the angles of abutment more acute, and would have produced a greater preffure on all the lower tiers when the frame fagged.

Fig. 7. reprefents the centering of the bridge of Orleans. The arch has 100 feet fpan, and rifes 30, and the archftones are 6 feet long. It is the conftruction of Mr Hupeau, the firft architect of the bridge. It is the boldeft work of the kind that we have feen, and is conftructed on clear principles. The main abutments are few in number. Becaufe the beams of the outer polygon are long, they are very well fupported by ftraining beams in the middle; and the ftruts or braces which fupport and butt on them, are made to reft on points carried entirely by *ties*. The inventor, however, feems to have thought that the angles of the inner polygon were fupported by mutual compreffion, as in the outer polygon. But it is plain that the whole inner polygon may be formed of iron rods. Not but that both polygons *may* be in a ftate of compreffion (this is very poffible); but the fmalleft fagging of the frame will change the proportions of the preffures at the angles of the two polygons. The preffures on the exterior angles will increafe, and thofe on the lower or interior angles will diminifh moft rapidly; fo that the abutments in the lower polygon will be next to nothing. Such points could bear very little preffure from the braces which fupport the middle of the long bearings of the upper beams, and their preffures muft be borne chiefly by the joints fupported by the king-pofts. The king-pofts would then be in a ftate of extenfion. It is difficult, however, to decide what is the precife ftate of the preffure at thefe interior angles. 20 Orleans.

21 Instructive history of this centre.

The history of the erection of this bridge will throw much light on this point, and is very instructive. Mr Hupeau died before any of the arches were carried farther than a very few of the first courses. Mr Perronet succeeded to the charge, and finished the bridge. As the work advanced, the crown of the frame rose very much. It was loaded; and it sunk as remarkably. This shewed that the lower polygon was giving very little aid. Mr Perronet then thought the frame too weak, and inserted the long beam DE, making the diagonal of the quadrangle, and very nearly in the direction of the lower beam *a b*, but falling rather below this line. He now found the frame abundantly strong. It is evident that the truss is now changed exceedingly, and consists of only the two long sides, and the short straining beam lying horizontally between their heads. The whole centering consists now of one great truss *a* E *e b*, and its long sides *a* E, *e b*, are trussed up at B and *f*. Had this simple idea been made the principle of the construction, it would have been excellent. The angle *a* DE might have been about 176°, and the polygon D *c g b* employed only for giving a slight support to this great angle, so as not to allow it to exceed 180°. But Mr Perronet found, that the joint *c*, at the foot of the post E *c*, was about to *draw loose*, and he was obliged to bolt long pieces of timber on each side of the joint, embracing both beams. These were evidently acting the same part as iron straps would have done; a complete proof that, whatever may have been the original pressures, there was no abutment now at the point *c*, and that the beams that met there were not in a state of compression, but were on the stretch. Mr Perronet says that he put these cheeks to the joints *to stiffen* them. But this was not their office; because the adjoining beams were not struts, but ties, as we have now proved.

We may therefore conclude, that the outer polygon, with the assistance of the pieces *a b*, DE, were carrying the whole load. We do not know the distance between the frames; but supposing them seven feet apart, and the arch 6 feet thick, and weighing 170 pounds per foot, we learn the load. The beams were 16 inches square. If we now calculate what they would bear at the same very moderate rate allowed to the other centres, we find that the beams AB and *a b* are not loaded to one-sixth of their strength.

We have given this centre as a fine example of what carpentry is able to perform, and because, by its simplicity, it is a sort of text on which the intelligent artist may make many comments. We may see plainly that, if the lower polygon had been formed of iron rods, firmly bolted into the feet of the king-posts, it would have maintained its shape completely. The service done by the beam DE was not so much an increase of abutment as a discharge of the weight and of the *pull* at the joint *c*. Therefore, in cases where the feet of the truss are *necessarily* confined to a very narrow space, we should be careful to make the upper polygon sufficient to carry the whole load (say by doubling its beams), and we may then make the lower polygon of slender dimensions, provided we secure the joints on the king-posts by iron straps which embrace a considerable portion of the tie on each side of the joint.

We are far from thinking that these centres are of the best kind that could be employed in their situation; but they are excellent in their kind; and a careful study of them will teach the artist much of his profession. When we have a clear conception of the state of strain in which the parts of a frame really are, we know what should be done in order to draw all the advantage possible from our materials. We have said in another place, that where we can give our joints sufficient connection (as by straps and bolts, or by cheeks or fishes), it is better to use ties than struts, because ties never bend.

22 All these centres good in their kind.

We do not approve of Mr Perronet's practice of giving his trusses such narrow feet. By bringing the foot of the lower polygon farther down, we greatly diminish all the strains, and throw more load on the lower polygon; and we do not see any of Mr Perronet's centres where this might not have been done. He seems to affect a great span, to shew the wonders of his art; but our object is to teach how to make the best centre of a given quantity of materials; and how to make the most perfect centre, when we are not limited in this respect, nor in the extent of our fixed points.

23 Excellence of the centre employed for Blackfriars bridge.

We shall conclude this series of examples with one where no such affectation takes place. This is the centering of the bridge at Blackfriars, London. The span of the arch is 100 feet, and its height from the spring is about 43. The drawing fig. 8. is sufficiently minute to convey a distinct notion of the whole construction. We need not be very particular in our observations, after what has been said on the general principles of construction. The leading maxim, in the present example, seems to be, *that every part of the arch shall be supported by a simple truss of two legs resting, one on each pier.* H, H, &c. are called APRON PIECES to strengthen the exterior joints, and to make the RING as stiff in itself as possible. From the ends of this apron-piece proceed the two legs of each truss. These legs are 12 inches square: They are not of an entire piece, but of several, meeting in firm abutment. Some of their meetings are secured by the double king-posts, which grasp them firmly between them, and are held together by bolts. At other intersections, the beams appear halved into each other; a practice which cannot but weaken them much, and would endanger their breaking by cross strains, if it were possible for the frame to change its shape. But the great breadth of this frame is an effectual stop to any such change. The fact was, that *no sinking or twisting whatever* was observed during the progress of the mason work. Three points in a straight line were marked on purpose for this observation, and were observed every day. The arch was more than six feet thick; and yet the sinking of the crown, before setting the key-stones, did not amount to one inch.

The centre employs about one-third more timber than Perronet's great centre in proportion to the span of the arch; but the circumference increases in a greater proportion than this, because it is more elevated. In every way of making a comparison of the dimensions, Mr Mylne's arch employs more timber; but it is *beyond all comparison* stronger. The great elevation is partly the reason of this. But the disposition of the timbers is also much more advantageous, and may be copied even in the low pitched arches of Neuilly. The simple truss, reaching from pier to pier for the middle point of the arch, gives the strong support where it is most of all wanted; and in the lateral points H, although

Center. though one leg of the truſs is very oblique, the other compenſates for it by its upright poſition.

The chief peculiarity of this centre is to be ſeen in its baſe. This demands a more particular attention; but we muſt firſt make ſome obſervations on the condition of an arch, as it reſts on the centering after the keyſtones are all ſet, and on the gradual transference of the preſſure from the boards of the centering to the joints of the archſtones.

24 Obſervations on the ſtate of an arch as it reſts on the centering.

While all the archſtones lie on the centering, the lower courſes are alſo leaning pretty ſtrongly on each other. But the mortar is hardly compreſſed in the joints; and leaſt of all in the joints near the crown. Suppoſe the arch to be Catenarean, or of any other ſhape that is perfectly equilibrated: When the centering is gradually withdrawn, all the archſtones follow it. Their wedge-like form makes this impoſſible, without the middle ones ſqueezing the lateral ones aſide. This compreſſes the mortar between them. As the ſtones thus come nearer to each other, thoſe near the crown muſt deſcend more than thoſe near the haunches, before every ſtone has leſſened its diſtance from the next by the ſame quantity; for example, by the hundredth part of an inch. This circumſtance alone muſt cauſe a ſinking in the crown, and a change of ſhape. But the joints near the crown are *already* more open than thoſe near the haunches. This produces a ſtill greater change of form before all is ſettled. Some maſons endeavour to remedy, or at leaſt to diminiſh, this, by uſing no mortar in the joints near the crown. They lay the ſtones dry, and even force them together by wedges and blocks laid between the ſtones on oppoſite ſides of the crown: They afterwards pour in fine cement. This appears a good practice. Perronet rejects it, becauſe the wedging ſometimes breaks the ſtones. We ſhould not think this any great harm; becauſe the fracture will make them cloſe where they would otherwiſe lie hollow. But, after all our care, there is ſtill a ſinking of the crown of the arch. By gradually withdrawing the centering, the joints cloſe, the archſtones begin to butt on each other, and to force aſide the lateral courſes. This abutment gradually increaſing, the preſſure on the haunches of the centering is gradually diminiſhed by the mutual abutment, and ceaſes entirely in that courſe, which is the loweſt that formerly preſſed it: it then ceaſes in the courſe above, and then in the third, and ſo on. And, in this manner, not only the centering quits the arch, gradually, from the bottom to the top, *by its own retiring from it*, but the arch alſo quits the centering *by changing its ſhape*. If the centering were now puſhed up again, it would touch the arch firſt at the crown; and it muſt *lift up* that part gradually before it come again in contact with the haunches. It is evident, therefore, that an arch, built on a centre of a ſhape perfectly ſuited to equilibration, will not be in equilibrio when the centering is removed. It is therefore neceſſary to form the centering in ſuch a manner (by raiſing the crown), that it ſhall *leave* the arch of a proper form. This is a very delicate taſk, requiring a previous knowledge of the enſuing change of form. This cannot be aſcertained by the help of any theory we are acquainted with.

But, ſuppoſe this attained, there is another difficulty: While the work advances, the centering is warped by the load laid on it, and continually increaſing on each ſide. The firſt preſſure on the centering forces down the haunches, and raiſes the crown. The arch is therefore leſs curved at the haunches than is intended: the joints, however, accommodate themſelves to this form, and are cloſe, and filled with mortar. When the maſons approach the middle of the arch, the frame ſinks there, and riſes up at the haunches. This opens all the joints in that place on the *upper* ſide. By the time that the keyſtones are ſet, this warping has gone farther; and joints are opened on the *under* ſide near the crown. It is true we are here ſpeaking rather of an extreme caſe, when the centering is *very* flexible; but this occurred to Mr Perronet in the two great bridges of Neuilly and of Mantz. In this laſt one, the crown ſunk above a foot before the key was ſet, and the joints at the haunches opened above an inch *above*, while ſome nearer the crown opened near a quarter of an inch *below*.

25 A delicate buſineſs to ſtrike the centering.

In this condition of things, it is a delicate buſineſs to ſtrike the centering. Were it removed in an inſtant, all would probably come down; for the archſtones are not yet abutting on each other, and the joints in the middle are open below. Mr Perronet's method appears to us to be very judicious. He began to detach the centering at the very bottom, on each ſide equally, where the preſſure on the centering is very ſlight. He cut away the blocks which were immediately under each archſtone. He proceeded gradually upwards in this way with ſome ſpeed, till all was detached that had been put out of ſhape by the bending of the centering. This being no longer ſupported, ſunk inward, till it was ſtopped by the abutment which it found on the archſtones near the crown which were ſtill reſting on their blocks. During part of this proceſs, the open joints opened ſtill more, and looked alarming. This was owing to the removal of the load from the haunches of the centering. This allowed the crown to ſink ſtill more, by forcing out the arch ſtones at the haunches. He now pauſed ſome days; and during this time the two haunches, now hanging in the air, gradually preſſed in toward the centering, their outer joints cloſing in the meanwhile. The haunches were now preſſing pretty hard on the arch ſtones nearer the crown. He then proceeded more ſlowly, deſtroying the blocks and bridgings of theſe upper archſtones. As ſoon as he deſtroyed the ſupport of one, it immediately yielded to the preſſure of the haunch; and if the joint between it and the one adjoining toward the crown happened to be open, whether on the under or the upper ſide, it immediately cloſed on it. But in proceeding thus, he found every ſtone ſink a little while it cloſed on its neighbour; and this was like to produce a ragged ſoffet, which is a deformity. He therefore did not allow them to ſink ſo much. In the places of the blocks and bridgings which he had cut away, he ſet ſmall billets, ſtanding on their ends, between the centering and the archſtones. Theſe allowed the pendulous arch to puſh toward the crown without ſenſibly deſcending; for the billets were puſhed out of the perpendicular, and ſome of them tumbled down. Proceeding in this way, he advanced to the very next courſe to the keyſtone on each ſide, the joints cloſing all the way as he advanced. The laſt job was very troubleſome; we mean the detaching the three uppermoſt courſes from the centering: for the whole elaſticity of the centering was now trying to unbend, and preſſing hard againſt them. He found that they were lifted up; for the joints

joints beyond them, which had cloſed completely, now opened again below: but this job was finiſhed in one day, and the centre ſprung up two or three inches, and the whole arch ſunk about ſix inches. This was an anxious time; for he dreaded the great momentum of ſuch a vaſt maſs of matter. It was hard to ſay where it would ſtop. He had the pleaſure to ſee that it ſtopped very ſoon, ſettling ſlowly as the mortar was compreſſed, and after one or two days ſettling no more. This ſettling was very conſiderable both in the bridge at Neuilly and in that at Mantz. In the former, the ſinking during the work amounted to 13 inches. It ſunk ſix inches more when the blocks and bridgings were taken out, and $1\frac{1}{2}$ when the little ſtandards were deſtroyed, and $1\frac{1}{4}$ more next day; ſo that the whole ſinking of the *pendulous* arch was $9\frac{1}{2}$ inches, beſides what it had ſunk by the bending and compreſſion of the centering.

The crown of the centering was an arch of a circle deſcribed with a radius of 150 feet; but by the ſinking of the arch its ſhape was conſiderably changed, and about 60 feet of it, formed an arch of a circle whoſe radius was 244 feet. Hence Mr Perronet infers, that a ſemicircle of 500 feet ſpan may be erected. It would no doubt be ſtronger that this arch, becauſe its greater horizontal thruſt would keep the ſtones firmer together. The ſinking of the arches at Mantz was not quite ſo great, but every thing proceeded in the ſame way. It amounted in all to $20\frac{1}{2}$ inches, of which 12 inches were owing to the compreſſion and bending of the centering.

26 The foregoing obſervations exemplified.

In fig. 5. n° 1. may be obſerved an indication of this procedure of the maſonry. There may be noticed a horizontal line *a c*, and a diagonal *a b*. Theſe are ſuppoſed to be drawn on the maſonry as it would have ſtood had the frames not yielded during the building. The dotted line A *b′ c′* ſhews the ſhape which it took by the ſinking of the centering. The dotted line on the other ſide was actually drawn on the maſonry when the keyſtone was ſet; and the wavy black line on the ſame ſide ſhews the form which the dotted line took by the ſtriking of the centering. The undulated part of this line cuts its former poſition a little below the middle, going without it below, and falling within it above. This ſhews very diſtinctly the movement of the whole maſonry, diſtinguiſhing the parts that were forced out and the parts which ſunk inward.

We preſume that the practical reader will think this account of the internal movements of a ſtupendous arch very inſtructive and uſeful. As Mr Perronet obſerved it to be uniformly the ſame in ſeveral very large arches which he erected, we may conclude that it is the general proceſs of nature. We by no means have the confidence in the durability or ſolidity of his arches which he prudently profeſſes to have. We have converſed with ſome very experienced maſons, who have alſo erected very great arches, and in very difficult ſituations, which have given univerſal ſatisfaction; and we have found them uniformly of opinion, that an arch which has ſettled to ſuch a proportion of its curvature as to change the radius from 150 to 244 feet, is in a very hazardous ſituation. They think the hazard the greater, becauſe the ſpan of the arch is ſo great in proportion to its weight (as they expreſs it very emphatically) or its height. The weight, ſay they, of the haunches is too ſmall for forcing together the keyſtones, which have ſcarcely any wedgelike form to keep them from ſliding down. This is very good reaſoning, and expreſſes very familiar notions. The mechanician would ſay, that the horizontal thruſt at the crown is too ſmall. When we queſtioned them about the propriety of Mr Perronet's method of removing the centering, they unanimouſly approved of its general principle, but ſaid that it was very tickliſh indeed in the execution. The caſes which he narrates were new to them. They ſhould have almoſt deſpaired of ſucceſs with arches which had gone ſo much out of ſhape by the bending of the centres; becauſe, ſaid they, the ſlope of the centering, to a great diſtance from the crown, was ſo little, that the archſtones could not ſlide outwards along it, to cloſe even the under ſide of the joints which had opened above the haunches; ſo that *all* the archſtones were at too great a diſtance from each other; and a great and *general* ſubſiding of the whole was neceſſary for bringing them even to touch each other. They had *never* obſerved ſuch bendings of the centerings which they had employed, having never allowed themſelves to contract the feet of their truſſes into ſuch narrow ſpaces. They obſerved, that nothing but lighters with their maſts down can paſs under the truſſes, and that the ſides muſt be ſo protected by advanced works from the accidental ſhock of a loaded boat, that there cannot be left room for more than one. They added, that the bridges of communication, neceſſary for the expeditious conducting of the work, made all this ſuppoſed roomineſs uſeleſs: beſides, the buſineſs can hardly be ſo urgent and crowded any where, as to make the paſſage through every arch indiſpenſably neceſſary. Nor was the inconvenience of this obſtruction greatly complained of during the erection of Weſtminſter or Blackfriars bridges. Nothing ſhould come in competition with the *undoubted* ſolidity of the centering and the future arch; and all boaſting diſplay of talent and ingenuity by an engineer, in the exhibition of the wonders of his art, is miſplaced here.

Theſe appeared to us good reaſons for preferring the more cautious, and incomparably more ſecure, conſtruction of Mr Mylne, in which the breadth given to each baſe of the truſſes permitted a much more effective diſpoſition of the abutting timbers, and alſo enabled the engineer to make it incomparably ſtiffer; ſo that no change need be apprehended in the joints which have already cloſed, and in which the mortar has already taken its ſet, and commenced an union that never can be reſtored if it be once broken in the ſmalleſt degree, no not even by greater compreſſion.

27 The connection that is formed by mortar of lime, &c.

Here we beg leave to mention our notions of the connection that is formed by mortar compoſed of lime or gypſum. We conſider it as conſiſting chiefly, if not ſolely, in a cryſtallization of the lime or gypſum and water. As much water is taken up as is neceſſary for the formation of the cryſtals during their gradual converſion into mild calcareous earth or alabaſter, and the reſt evaporates. When the free acceſs of air is abſolutely prevented, the cryſtallization never proceeds to that ſtate, even although the mortar becomes extremely dry and hard. We had an opportunity of obſerving this accidentally, when paſſing through Maeſtricht in 1770, while they were cutting up a maſſy revetment of a part

Center.

a part of the fortifications more than 300 years old. The mortar between the bricks was harder than the bricks (which were Dutch clinkers, ſuch as are now uſed only for the greateſt loads); but when mixed with water it made it limewater, ſeemingly as ſtrong as if freſh lime had been uſed. We obſerved the ſame thing in one ſmall part of a huge maſs of ancient Roman work near Romney in Kent; but the reſt, and all the *very old* mortar that we have ſeen, was in a mild ſtate, and was generally much harder than what produced any lime water. Now when the mortar in the joints has begun its firſt cryſtallization, and is allowed to remain in perfect reſt, we are confident that the ſubſequent cryſtals, whether of lime, or of calcareous earth, or of gypſum, will be much larger and ſtronger than can ever be produced if they are once broken; and the farther that this cryſtallization has been carried, that is, the harder that the mortar has become, leſs of it remains to take any new cryſtallization. Why ſhould it be otherwiſe here than in every other cryſtallization that we are acquainted with?

28 Neceſſity of keeping the joints in their firſt ſtate.

We think therefore that it is of great conſequence to keep the joints in their *firſt* ſtate if poſſible; and that the ſtrength (as far as it depends on the mortar) is greatly diminiſhed by their opening; eſpecially when the mortar has acquired conſiderable hardneſs, which it will do in a month or ſix weeks, if it be good. The coheſion given by mortar is indeed a mere trifle, when oppoſed to a force which tends to open the joints, acting, as it generally does, with the tranſverſe force of a lever: but in ſituations where the overload on any particular archſtones tends to puſh them down through between their neighbours, like wedges, the coheſion of the mortar is then of very great conſequence.

We muſt make another obſervation. Mr Perronet's ingenious proceſs tended very effectually to cloſe the joints. In doing this, the forces which he brought into action had little to oppoſe them; but as ſoon as they were cloſed, the contact of the parts formerly open oppoſed an obſtruction incomparably greater, and immediately balanced a force which was but juſt able to turn the ſtone gently about the two edges in which it touched the adjoining ſtones. This is an important remark, though ſeemingly very trifling; and we wiſh the practitioner to have a very clear conception of it; but it would take a multitude of words to explain it. It is worth an experiment. Form a little arch of wooden blocks; and form one of theſe ſo, that when they are all reſting on the centering, it may be open at the outer joint—Remove the centering—Then preſs on the arch at ſome diſtance from the open joint.—You will find that a very ſmall preſſure will make the arch bend till that joint cloſes—Preſs a little harder, and the arch will bend more, and the next joint will open.—Thus you will find that, by preſſing alternately on each ſide of the open joint, that ſtone can eaſily be made to flap over to either ſide; and that immediately after this is done the reſiſtance increaſes greatly. This ſhews clearly, that a very moderate force, judiciouſly employed, will cloſe the joints, but will not preſs the parts ſtrongly together. The joints therefore are *cloſed*, but *no more than cloſed*, and are hanging only by the edges by which they were hanging while the joints were open. The arch, therefore, though apparently cloſe and firm, is but looſe and tottering. Mr Perronet ſays, that his arches were firm, becauſe hardly a ſtone was obſerved to chip or ſplinter off at the edges by the ſettlement. But he had done every thing to prevent this, by digging out the mortar from between the headers, to the depth of two inches, with ſaws made on purpoſe. But we are well informed, that before the year 1791 (twenty years after the erection) the arches at Neuilly had ſunk very ſenſibly, and that very large ſplinters had flown off in ſeveral places. It could not be otherwiſe. The original conſtruction was too bold; we may ſay needleſsly and oſtentatiouſly bold. A very gentle ſlope of the roadway, which would not have ſlackened the mad gallop of a ducal carriage, nor ſenſibly checked the laborious pull of a loaded waggon, and a proper difference in the ſize of the arches, would have made this wonderful bridge incomparable ſtronger, and alſo much more elegant and pleaſing to the eye. Indeed, it is far from being as handſome as it might have been. The ellipſe is a moſt pleaſing figure to every beholder; but this is concealed as much as poſſible, and it is attempted to give the whole the appearance of a tremendous lintel. It has the oppreſſive look of danger. It will not be of long duration. The bridge at Mantz is ſtill more exceptionable, becauſe its piers are tall and ſlender. If any one of the arches fails, the reſt muſt fall in a moment. An arch of Blackfriars Bridge might be blown up without diſturbing its neighbours.

29 Mr Perronet's conſtructions too bold.

30 A bad method of ſtriking the centre.

Mr Perronet mentions another mode of ſtriking the centering, which he ſays is very uſual in France. Every ſecond bridging is cut out. Some time after, every ſecond of the remainder; after this, every ſecond of the remainder; and ſo on till all are removed. This is never practiſed in this country, and is certainly a very bad method. It leaves the arch hanging by a number of diſtant points; and it is wonderful that any arch can bear this treatment.

31 The common method in Britain.

Our architects have generally proceeded with extreme caution. Wherever they could, they ſupported the centering by intermediate pillars, even when it was a truſſed centre, having a tie-beam reaching from ſide to ſide. The centre was made to reſt, not immediately on theſe pillars, but on pieces of timber formed like acute wedges, placed in pairs, one above the other, and having the point of the one on the thick end of the other. Theſe wedges were well ſoaped and rubbed with black lead, to make them ſlippery. When the centres are to be ſtruck, men are ſtationed at each pair of the wedges with heavy mauls. They are directed to ſtrike together on the oppoſite wedges. By this operation the whole centering deſcends together; or, when any part of the arch is obſerved to have opened its joints on the upper ſide, the wedges below that part are ſlackened. The framing may perhaps bend a little, and allow that part to ſubſide. If any part of the arch is obſerved to open its joints on the under ſide, the wedges below that part are allowed to ſtand after the reſt have been ſlackened. By this proceſs, the whole comes down gradually, and as ſlowly as we pleaſe, and the defects of every part of the arch may be attended to. Indeed the caution and moderation of our builders have commonly been ſuch, that few defects have been allowed to ſhew themſelves. We are but little acquainted with joints opening to the extent of two inches, and in ſuch a caſe would probably lift

Center. lift every stone of the arch again (B). We have not employed trussed centerings so much perhaps as we should have done; nor do we see their advantage (speaking as mere builders) over centres supported all over, and unchangeable in their form. Such centres must bend a little, and require loading on the middle to keep them in shape. Their compression and their elasticity are very troublesome in the striking of the centres in Mr Perronet's manner. The elasticity is indeed of use when the centres are struck in the way now described.

These observations on the management of the internal movements of a great arch, will enable the reader to appreciate all the merit of Mr Mylne's very ingenious construction. We proceed therefore to complete our description.

The gradual enlargement of the base of the piers of Blackfriars bridge enabled the architect to place a series of five posts *c*, *c*, *c*, *c*, *c*, one on each stap of the pier; the ingenious contexture of which made it like one solid block of stone (see ARCH, *Supplement*). These struts were gradually more and more oblique, till the outer one formed an obtuse angle with the lowest side of the interior polygon of the truss. On the top of these posts was laid a sloping SEAT or beam D of stout oak, the upper part of which was formed like a zig-zag scarfing. The posts were not perpendicular to the under side of the seat. The angles next the pier were somewhat obtuse. Short pieces of wood were placed between the heads of the posts (but not mortised into them), to prevent them from slipping back. Each face of the scarf was covered with a thick and smooth plate of copper. The feet of the truss were mortised into a similar piece F, which may be called the SOLE of the truss, having its lower side notched in the same manner with the upper side of D, and like it covered with copper. Between these two lay the STRIKING WEDGE E, the faces of which corresponded exactly with the slant faces of the seat and the sole. The wedge was so placed, that the corresponding faces touched each other for about half of their length. A block of wood was put in at the broad end or base of this wedge, to keep it from slipping back during the laying the archstones. Its outer end E was bound with iron, and had an iron bolt several inches long driven into it. The head of this bolt was broad enough to cover the whole wood of the wedge within the iron ferrule.

32 The excellence of Mr Mylne's method.

We presume that the reader, by this time, foresees the use of this wedge. It is to be driven in between the sole and the seat (having first taken out the block at the base of the wedge). As it advances into the wider spaces, the whole truss must descend, and be freed from the arch; but it will require prodigious blows to drive it back. Mr Mylne did not think so, founding his expectation on what he saw in the launching of great ships, which slide very easily on a slope of 10 or 12 degrees. He rather feared, that taking out the block behind would allow the wedge to be pushed back at once, so that the descent of the truss would be too rapid. However, to be certain of the operation, he had prepared an abundant force in a very ingenious manner. A heavy beam of oak, armed at the end with iron, was suspended from two points of the centre like a battering ram, to be used in the same manner. Nothing could be more simple in its structure, more powerful in its operation, or more easy in its management. Accordingly the success was to his wish. The wedge did not slip back of itself; and very moderate blows of the ram drove it back with the greatest ease. The whole operation was over in a very few minutes. The spectators had suspected, that the space allowed for the recess of the wedge was not sufficient for the settlement of the arch; but the architect trusted to the precautions he had taken in its construction. The reader, by turning to the article ARCH in this *Supplement*, will see, that there was only the arch LY which could be expected to settle: accordingly, the recess of the wedge was found to be much more than was necessary. However, had this not been the case, it was only necessary to take out the pieces between the posts below the seat, and then to drive back the heads of the struts; but this was not needed (we believe) in any of the arches. We are well assured that none of the arches sunk an inch and a half. The great arch of 100 feet span did not sink one inch at the crown. It could hardly be perceived whether the arch quitted the centering gradually or not, so small had been the changes of shape.

33 The great superiority of the centering used by him.

We have no hesitation in saying, that (if we except some waste of great timber by uncommon joggling) the whole of this performance is the most perfect of any that has come to our knowledge. We doubt not but that several have equalled it, or may have excelled it; but we do not know of them: and we think, that the bringing forward such performances is no less serviceable to the public than it is honourable to the inventor. Nor do we suppose that any views of interest can be so powerful as to prevent an ingenious architect from communicating to the public such honourable specimens of his own talents. We should be happy to communicate more of this kind; for we consider it as a very important article of practical mechanics, and think that it is of consequence to the nation that it should be very generally understood. In every corner of the country bridges are to be built—we have everywhere good *masons*, who are fully able to execute any practicable project, but too little acquainted with principle to invent, or to accommodate even what they know to local circumstances, and are very apt to be duped by appearances of ingenuity, or misled by erroneous notions of the strains which are excited. We profess more science, and to treat the subject with the assistance of accurate principles: But while we are certain that every circumstance is susceptible of the most accurate determination, we must acknowledge that we have by no means attained an accurate knowledge of all the strains which are produced

(B) The writer of this article can only say, that, after much inquiry, he has no information of any arch being received from the builder as sufficient that had suffered half the change of shape mentioned by Mr Perronet. The arch of Dublin bridge, built by an excellent, but a very private, mason, Mr Steven, is 105 feet wide, with only 22 feet of rise. It was erected (but not on a trussed centering) without changing one full inch in its elevation; and when the centering was removed, it sunk only $1\frac{1}{4}$th inches, and about half an inch more when the parapets were added and the bridge completely finished.

produced and excited in a frame of carpentry, which is ſettling and changing its ſhape, even though it be not very complicated; far leſs are we poſſeſſed of a clear view of what happens in a maſs of maſonry in ſimilar conditions. Therefore, though we ſpeak with the ſtrong belief of our being right, we ſpeak with a ſenſe of our fallibility, and with great deference to the judgment of eminent and experienced architects and engineers. We ſhould conſider their free and candid criticiſms as the higheſt favour; and we even ſolicit them, with aſſurances of thanks, and that we will take ſome opportunity, before the cloſe of this work, to acknowledge and correct our miſtakes. We even preſume to hope, that the liberal minded artiſt will be pleaſed with this opportunity which we give him of increaſing the national ſtock of knowledge. Let mutual jealouſy and rivalſhip reign in the breaſts, and prompt the exertions, of our reſtleſs neighbours on the continent—let them think that the dignity of man conſiſts in perpetual warfare, in which every individual feels himſelf indebted only to himſelf, freed from all the ſweet ties of domeſtic partiality, of friendſhip, and of patriotic attachment. We hope that the hearts of Britons will long continue to be warmed and *fortified* by the thoughts of mutual aſſiſtance, mutual co-operation, mutual attachment, and a patriotic preference of their countrymen to all other men. While theſe ſentiments are regulated by unſhaken honeſty, by candour, and by Chriſtian charity, we ſhall be ſecured from the *errors* of partial attachments, and yet enjoy all the pleaſures of unſophiſticated nature. Families will ſtill be bound together by the affectionate ties of blood; and the whole frame of Britiſh ſociety will be in harmony with the bonds which connect the members of each family, by their endleſs croſſings and intermixings. In this ſtate, the ſtate of ſocial nature, the man of talents will not lock up all the fruits of his exertions in his own breaſt, but will feel a pleaſure in imparting them to a ſociety that is dear to him, and on which he depends for all his beſt enjoyments. Nothing will hold the good man back when this is in his power, but the virtuous uſe which he can make of his ſuperiority in the diſcharge of his own little circle of duties. This is all that is required of true patriotiſm; and it is not too much to be expected from Britons, who feel a pleaſure in viewing their country as the great ſchool of the arts, under the patronage of a ſovereign who has done more for their improvement than all the other princes of Europe, and who (we are well aſſured) is now meditating a plan which muſt be highly gratifying to every eminent profeſſor of the arts.

34 The ſubject of this article connected with the conſtruction of wooden bridges.

THE ſubject which we have been conſidering is very cloſely connected with the conſtruction of wooden bridges. Theſe are not always conſtructed on the ſole principles of equilibrium, by means of mutual abutment. They are ſtiff frames of carpentry, where, by a proper diſpoſition, beams are put into a ſtate of extenſion, as well as of compreſſion, ſo as to ſtand in place of ſolid bodies as big as the ſpaces which the beams incloſe; and thus we are enabled to couple two, three, or four of theſe together, and ſet them in abutment with each other like mighty archſtones. We ſhall cloſe this article, therefore, with two or three ſpecimens of wooden bridges, diſpoſed in a ſeries of progreſſive compoſition, ſo as to ſerve as a ſort of introduction to the art in general, and furniſh a principle which will enable the intelligent and cautious artiſt to puſh it with confidence as far as it can go.

The general problem is this. Suppoſe that a bridge is to be thrown over the ſpace AB (fig. 9.), and that this is too wide for the ſtrength of the ſize of timber which is at our command; how may this beam AB be ſupported with ſufficient effect? There are but two ways in which the middle point C (where the greateſt ſtrain is) can be ſupported: 1. It may be ſuſpended by two ropes, iron rods, or wooden ties, DC, EC, made faſt to two firm points D, E, above it; or it may reſt on the ridge of two rafters *d* C, *e* C, which reſt on two firm points *d*, *e* below it. 2. It may be ſupported by connecting it with a point ſo ſupported; and this connection may be formed either by ſuſpending it from this point, or by a poſt reſting on it. Thus it may hang, by means of a rod or a king-poſt FC, from the ridge F of two rafters AF, BF; or it may reſt on the ſtrut C *f*, whoſe lower extremity *f* is carried by the ropes, rods, or wooden ties A *f*, B *f*. Plate XVI.

Whichſoever of theſe methods we employ, it follows, from the principles of carpentry, that the ſupport given to the point C is ſo much the more powerful, as we make the angle DCE, or *d* C *e*, or the equivalent angles AFB, or A *f* B, more acute.

Each of theſe methods may be ſuppoſed equally ſtrong. Our choice will depend chiefly on the facility of finding the proper points of ſupport D, E, *d*, *e*: except in the ſecond caſe, where we require no fixed points but A and B. The ſimple forms of the firſt caſe require a great extent of figure. Very rarely can we ſuſpend it from points ſituated as D and E. It is even ſeldom that we have depth enough of bank to allow the ſupport of the rafters *d* C, *e* C; but we can always find room for the ſimple truſs AFB. This therefore is the moſt uſually practiſed. 35 The uſual and ſimpleſt method of conſtructing ſuch bridges.

In the conſtruction, we muſt follow the maxims and directions preſcribed in the article CARPENTRY of this volume, and the article ROOF of the *Encycl.* The beams FA, FB muſt be mortiſed into AB, in the firmeſt manner, and there ſecured with ſtraps and bolts; and the middle muſt hang by a ſtrap attached to the king poſt FC, or to the iron rod that is uſed for a king poſt. No mortiſing in the point C muſt be employed; it is unneceſſary, and it is hurtful, becauſe it weakens the beam, and becauſe it lodges water, and ſoon decays by rot. The beſt practice is not to ſuſpend the beam immediately by this ſtrap, but to let it reſt, as in fig. 10. on a beam C, which croſſes the bridge below, and has its other end ſupported in the ſame manner by the other truſs.

It is evident that the length of the king poſt has no effect on the ſupport of C. We may therefore contract every thing, and preſerve the ſame ſtrength of ſupport, by finding two points *a* and *b* (fig. 11.) in the banks, at a moderate diſtance below A and B, and ſetting up the rafters *a* F, *b* F, and ſuſpending C from the ſhortened king poſt. In this conſtruction, when the beam AB reſts on a croſs bearer, as is drawn here, the ſtruts *a* F, *b* F are kept clear of it. No connection between them is neceſſary, and it may be hurtful, by inducing croſs ſtrains on both. It will, however, greatly increaſe creafe the ftiffnefs of the whole. This conftruction may fafely be loaded with ten times the weight that AB can carry alone.

36 An improvement of that method.

Suppofe this done, and that the fcantling of AB is too weak for carrying the weight which may be brought on the parts AC, CB. We may now trufs up each half, as in fig. 12. and then the whole will form a handfome bridge, of the fimpleft conftruction poffible. The interfections of the fecondary braces with thofe of the main trufs will form a hand-rail of agreeable figure.

We are not confined to the employment of an entire piece AB, nor to a rectilineal form. We may frame the bridge as in fig. 13. and in this form we diffuade from allowing any connection with the middle points of the main braces. This conftruction alfo may be followed till each beam AC and CB is loaded to ten times what it can fafely bear without the fecondary truffing.

37 Another method.

There is another way by which a bridge of one beam may be fupported beyond the power of the firft and fimpleft conftruction. This is reprefented in fig. 14. and fig. 15. The trufs beam FG fhould occupy one-third of AB. The advantage of this conftruction is very confiderable. The great elevation of the braces (which is a principal element of the ftrength) is preferved, and the braces are greatly fhortened.

This method may be pufhed ftill further, as in fig. 16.

38 Thefe methods combined.

And all thefe methods may be combined, by joining the conftructions of fig. 14. and fig. 15. with that of fig. 16.

In all of them there is much room for the difplay of fkill, in the proper adjuftment of the fcantling of the timber, and the obliquity of the braces to the lengths of the different bearings. A very oblique ftrut, or a flender one, will fuffice for a fmall load, and may often given an opportunity to increafe the general ftrength; while the great timbers and upright fupports are referved for the main preffures. Nothing will improve the compofition fo much as reflecting progreffively, and in the order of thefe examples, on the whole. This alone can preferve the great principle in its fimplicity and full energy.

39 The elements of all that can be done in this art.

Thefe conftructions are the elements of all that can be done in the art of building wooden bridges, and are to be found more or lefs obvioufly and diftinctly in all attempts of this kind. We may affert, that the more obvioufly they appear, the more perfect the bridge will be. It is aftonifhing to what extent the principle may be carried. We have feen a bridge of 42 feet fpan formed of two oak truffes, the biggeft timber of which did not exceed fix inches fquare, bearing with perfect fteadinefs and fafety a waggon loaded with more than two tons, drawn by four ftout horfes. It was framed as fig. 16. nearly, with the addition of the dotted lines, and was near thirty years old; protected, however, from the weather by a wooden roof, as many bridges in Germany are.

We recollect another in the neighbourhood of Stettin, which feemed conftructed with great judgment and fpirit. It had a carriage road in the middle about 20 feet (we think) wide, and on each fide a foot way about five feet wide. The fpan was not lefs than 60 feet, and the greateft fcantling did not appear to exceed 10 inches by 6.

This bridge confifted of four truffes, two of which formed the outfide of the bridge, and the other two made the feparation between the carriage road and the two foot ways. We noticed the conftruction of the truffes very particularly, and found it fimilar to the laft, except in the middle divifion of the upper trufs, which, being very long, was double truffed, as in fig. 17.

The reader will find in that volume of Leupold's *Theatrum Machinarum*, which he calls *Theatrum Pontificum*, many fpecimens of wooden bridges, which are very frequent in the champain parts of Germany. They are not, in general, models of mechanic art; but the reflecting reader, who confiders them *carefully*, will pick up here and there fubordinate hints, which are ingenious, and may fometimes be ufeful.

What we have now exhibited are not to be confidered as models of conftruction, but as elementary examples and leffons, for leading the reader fyftematically into a thorough conception of the fubject.

40 A wonderful bridge in Switzerland.

We cannot quit the fubject without taking notice of a very wonderful bridge at Wittingen in Switzerland, flightly defcribed by Mr Coxe (*Travels*, vol. I. 132.) It is of a conftruction more fimple ftill than the bridges we have been defcribing. The fpan is 230 feet, and it rifes only 25. The fketch (fig. 18.) will make it fufficiently intelligible. ABC is one of two great arches, approaching to a Catenarean fhape, built up of feven courfes of folid logs of oak, in lengths of 12 or 14 feet, and 16 inches or more in thicknefs. Thefe are all picked of a natural fhape, fuited to the intended curve; fo that the wood is nowhere cut acrofs the grain to trim it into fhape. Thefe logs are laid above each other, fo that their abutting joints are alternate, like thofe of a brick wall; and it is indeed a wooden wall, fimply built up, by laying the pieces upon each other, taking care to make the abutting joints as clofe as poffible. They are not faftened together by pins or bolts, or by fcarfings of any kind. They are, however, held together by iron ftraps, which furround them, at the diftance of five feet from each other, where they are faftened by bolts and keys.

Thefe two arches having been erected (by the help, we prefume, of pillars, or a centering of fome kind), and well butted againft the rock on each fide, were freed from their fupports, and allowed to fettle. They are fo placed, that the intended road *a b c* interfects them about the middle of their height. The roadway is fupported by crofs joifts, which reft on a long horizontal fummer beam. This is connected with the arches on each fide by uprights bolted into them. The whole is covered with a roof, which projects over the arches on each fide to defend them from the weather. Three of the fpaces between thefe uprights have ftruts or braces, which give the upper work a fort of truffing in that part.

This conftruction is fimple and artlefs; and appears, by the attempt to trufs the ends, to be the performance of a perfon ignorant of principle, who has taken the whole notion from a ftone arch. It is, however, of a ftrength much more than adequate to any load that can be laid on it. Mr Coxe fays, but does not explain

how,

Center.

how, that it is so contrived that any part of it can be repaired independent of the rest. It was the last work of one Ulrich Grubenhamm of Tuffen, in the canton of Appenzel, a carpenter without education, but celebrated for several works of the same kind; particularly the bridge over the Rhine at Schafhausen, consisting of two arches, one of 172 and the other of 193 feet span, both resting on a small rock near the middle of the river.

41 Another in North America.

While writing this article, we got an account of a wooden bridge erected in North America, in which this simple notion of Grubenhamm's is mightily improved. The span of the arch was said to exceed 250 feet, and its rise exceedingly small. The description we got is very general, but sufficient, we think, to make it perfectly intelligible.

In fig. 19. DD, EE, FF, are supposed to be three beams of the arch. They consist of logs of timber of small lengths, suppose of 10 or 12 feet, such as can be found of a curvature suited to its place in the arch without trimming it across the grain. Each beam is double, consisting of two logs applied to each other, side to side, and *breaking joint*, as the workmen term it. They are kept together by wedges and keys driven through them at short intervals, as at K, L, &c.

The manner of joining and strongly binding the two side pieces of each beam is shewn in fig. 20. The mortise *a i c b* and *d c i o*, which is cut in each half beam, is considerably longer on the outside than on the inside, where the two mortises meet. Two keys, BB and CC, are formed, each with a notch *b c d*, or *a i o*, on its side; which notch fits one end of the mortise. The inner side of the key is straight, but so formed, that when both keys are in their places, they leave a space between them wider at one end than at the other. A wedge AA, having the same taper as the space just mentioned, is put into it and driven hard. It is evident that this must hold the two logs firmly together.

This is a way of uniting timber not mentioned in the article Carpentry; and it has some peculiarities worthy of notice. In the first place, it may be employed so as to produce a very strong lateral connection, and would then co-operate finely with the other artificial methods of scarfing and tabling that we described in the article referred to. But it requires nice attention to some circumstances of construction to secure this effect. If the joints are accurately formed to each other, as if the whole had been one piece divided by an infinitely thin saw, this manner of joining will *keep* them all in their places. But no driving of the wedge AA will make them firmer, or cause one piece to press hard on the other. If the abutment of two parts of the half beam is already close, it will remain so; but if open in the smallest degree, driving of the wedge will not make it tighter. In this respect, therefore, it is not so proper as the forms described in Carpentry.

In order that the method now described may have the effect of *drawing* the halves of the beams together, and of keeping them hard squeezed on each other, the joints must be made so as not to correspond exactly. The prominent angle *a i o* (fig. 21.), formed by the ends of the two half mortises, must be made a little more obtuse than the angle *a f o* of the notch of the key which this prominence is intended to fill up. Moreover, the opposite side *e t* of this key should not be quite straight, but a very little convex. With these precautions, it is easy to see that, by driving the wedge AA, we cause the notch *a f o* to take hold, first at the two points *a* and *o*, and then, by continuing to drive the wedge, the sides *a f*, *o f*, of the notch gradually compress the wood of the half beams, and press them on each other. By continuing to drive the wedge, the mutual compression of the key and the beam squeezes all together, and the space *a f o i* is completely filled up. We may see, from this process, that the mutual compression and drawing together of the timber will be greater in proportion as we make the angle *a i o* more prominent, and its corresponding angle *a f o* more deep; always taking care that the key shall be thick enough not to break in the narrow part.

Center.

This adjustment of the keys to the mortise is necessary on another account. Supposing the joints to fit each other exactly before driving the wedge, and that the whole shrinks a little by drying—by this the angle *a i o* will become more prominent, and the angle *a f o* will become more shallow; the joint will open at *a* and *o*, and the mutual compressure will be at an end.

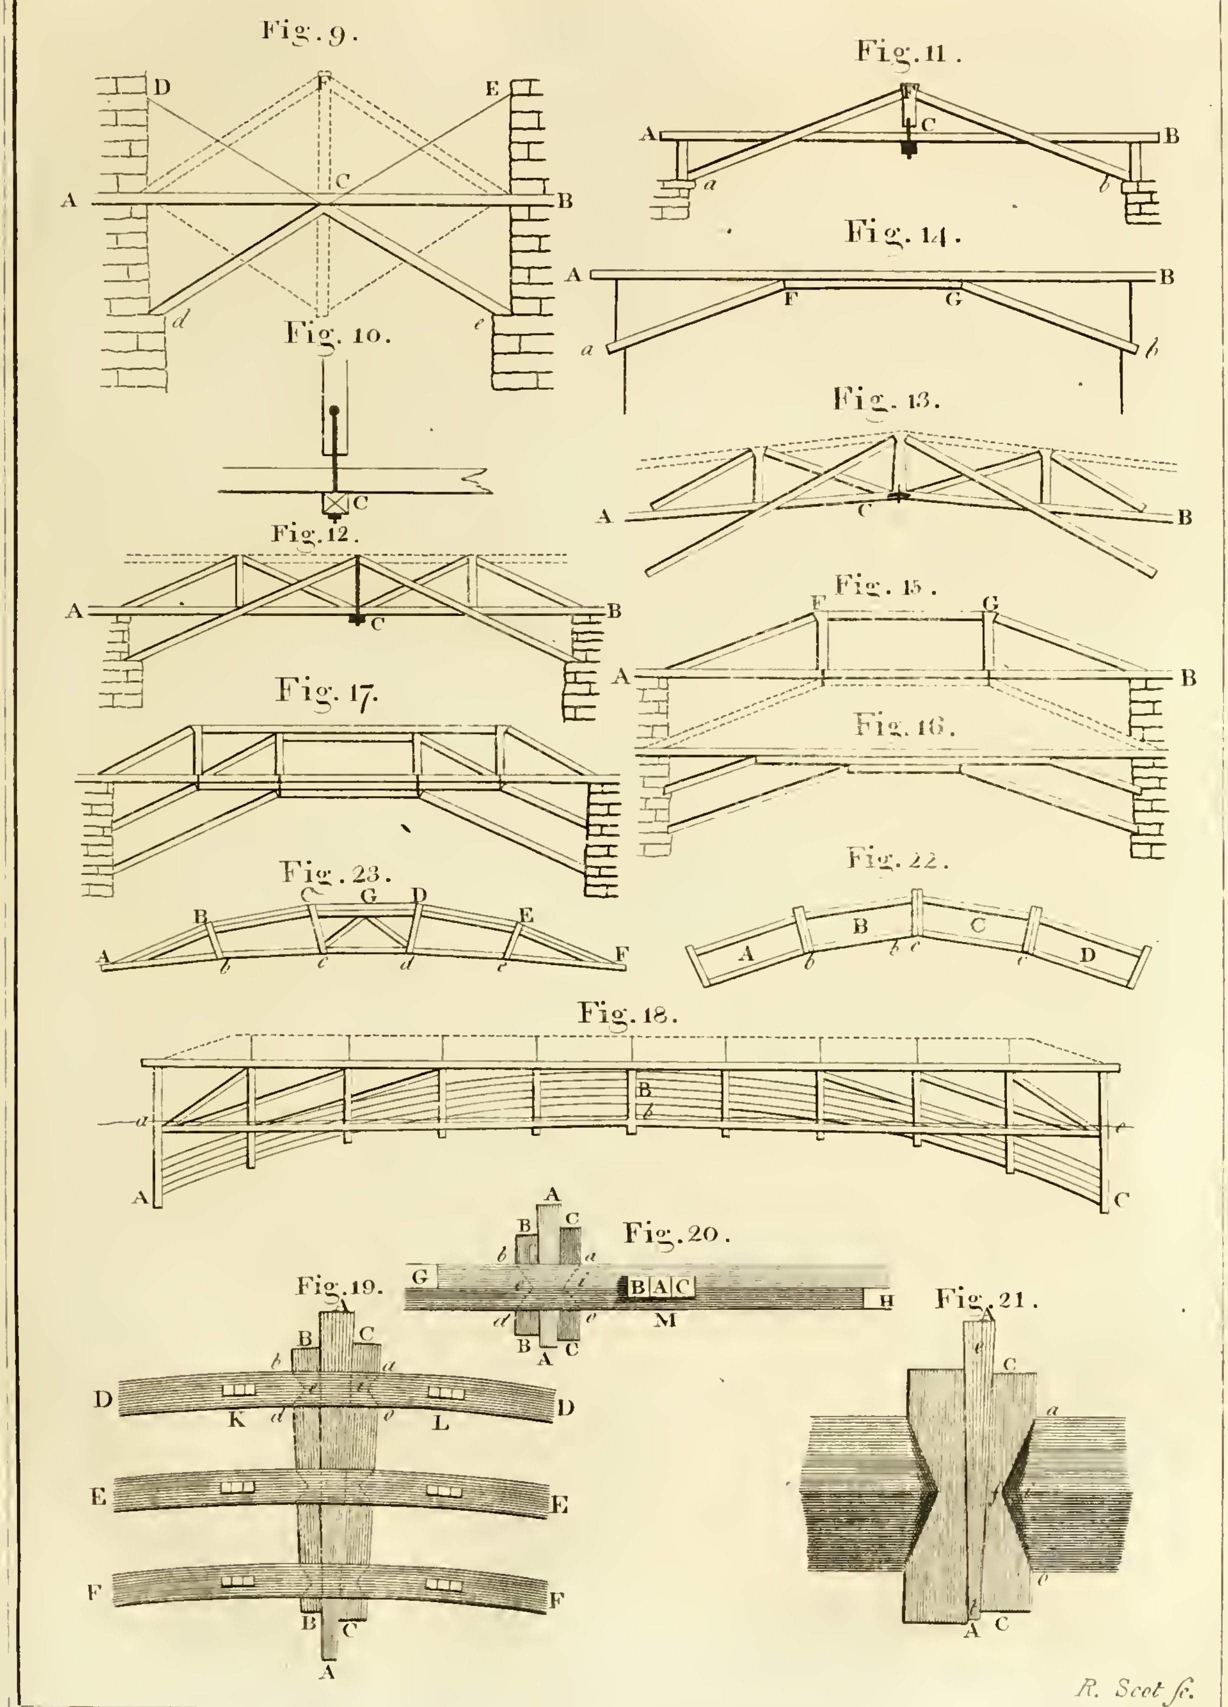
We may also observe, that this method will not give any additional firmness to the abutments of the different lengths employed to piece out the arch-beam; in which respect it differs materially from the other modes of joining timber.

Having shown how each beam is pieced together, we must now show how a number of them are united, so as to compose an arch of any thickness. This is done in the very same way. The beams have other mortises worked out of their inner sides, half out of each half of the beam. The ends of the mortises are formed in the same way with those already described. Long keys BB, CC, (fig. 19.) are made to fit them properly, the notches being placed so as to keep the beams at a proper distance from each other. It is now plain that driving in a long wedge AA will bind all together.

In this manner may an arch be extended to any span, and made of any thickness of arching. The bridge over Portsmouth river, in North America, was more than 250 feet in length, and consisted of several parallel arches of beams. The inventor (Mr Blodget) said that he found the strength so great, that he could with perfect confidence make one of four times the span.

We admire the ingenuity of this construction, and think it very effectual for bringing the timbers into firm and uniform abutment; but we imagine that it requires equilibration, because it is extremely flexible. There is nothing to keep it from bending, by an inequality of load, but the transverse strength of the beams. The keys and wedges can have very little power to prevent this bending. The distance between the beams will also contribute little or nothing to the stiffness; nay, we imagine that a great distance between them will make the frame more flexible. Could the beams be placed so near each other that they could be somehow joggled on each other, the whole would be stiffer; but at present they will bend like the plates of a coach-spring. But nothing hinders us from adding diagonal pieces to this construction, which will give it any degree of stiffness, and will enable it to bear any inequality of loading. When completed in this manner, we imagine that it will be at least equal to any construction

CENTRES. Plate XVII.



tion that has yet been thought of. One advantage it possesses that is very precious: Any piece that fails may be taken out, and replaced by another, without disturbing the rest, and without the smallest risk. On the whole, we think it a very valuable addition to British carpentry. The method here practised, both for joining the parts of one beam and for framing the different beams together, suggests the most firm and light constructions for dome-roofs that can be conceived; incomparably superior to any that have yet been erected. The whole may be framed, without a nail or a spike, into one net-like shell that cannot even be pulled in pieces. We may perhaps consider this in another article; at present we return to the consideration of trussed bridges.

42 Bridges combined by simple addition or by composition.

When the width of the river exceeds what is thought practicable by a single truss, we must then combine, either by simple addition, or by composition, different trusses together. We compose a bridge by simple addition when we make a frame of carpentry of an unchangeable and proper shape, to serve as one of the archstones of a bridge of masonry. This may easily be comprehended by looking at fig. 22. Each of the frames A, B, C, D, must be considered as a separate body, and all are supported by their mutual abutment. The nature of the thing is not changed, although we suppose that the rails of the frame B, instead of being mortised into an upright *b′ b′*, unconnected with the frame C, is mortised into the upright *c c* of that frame, the direction and intensity of the mutual pressures of the two frames are the same in both cases; accordingly this is a very common form of small wooden bridges. It is usual, indeed, to put diagonal battens into each: but we believe that this is more frequently done to please the eye than to produce an unalterable shape of each frame.

To an unskilful carpenter this bridge does not seem essentially different from the centering of Mr Hupeau for the bridge of Orleans; and indeed, in many cases, it requires reflection, and sometimes very minute reflection, to distinguish between a construction which is only an addition of frame to frame till the width be covered, from a construction where one frame works on the adjoining one transversely, pushing it in one part, and drawing it in another. The ready way for an unlettered artist to form a just notion of this point, is to examine whether he may saw through the connecting piece *b′ b′* from one end to the other, and make them two separate frames. Whenever this cannot be done without that part opening, it is a construction by composition. Some of the beams are on the stretch; and iron straps, extending along both pieces, are necessary for securing the joint. The bridge is no longer a piece of masonry, but a performance of pure carpentry, depending on principles peculiar to that art. Equilibration is necessary in the first construction; but, in the second, any inequality of loading is made ineffectual for hurting the edifice, by means of the stretch that is made to operate on some other piece. We are of opinion, that this most simple employment of the distinguishing principle of carpentry, by which the beams are made to act as ties, will give the most perfect construction of a wide bridge. One polygon alone should contain the whole of the abutments; and one other polygon should consist entirely of ties; and the beams which form the radii, connecting the angles of the two polygons, complete the whole. By confining the attention to these two simple objects, the abutments of the outer polygon, and the joints of the inner one, may be formed in the most simple and efficient manner, without any collateral connections and dependencies, which divide the attention, increase the complication, and commonly produce unexpected and hurtful strains. It was for this reason that we have so frequently recommended the centering of the bridge of Orleans. Its office will be completely performed by a truss of the form of fig. 23.; where the polygon ABCDEF, consisting of two layers of beams (if one is not sufficient), contains the whole abutments, and the other A *b c d e* F is nothing but an iron rod. In this construction, the obtuseness of the angles of the lower polygon is rather an advantage. The braces G *c*, G *d*, which are wanted for trussing the middle of the outer beams, will effectually secure the angles of the exterior polygon against all risk of change. The reader must perceive that we have now terminated in the construction of the Norman roof. We indeed think it the best general form, when some moderate declivity is not an insuperable objection. When this is the case, we recommend the general plan of the centering of the bridge of Orleans. We would make the bridge (we speak of a great bridge) consist of four trusses; two to serve as the outsides of the bridge, and two inner trusses, separating the carriage-way from the foot-paths. The road should follow the course of the lower polygon, and the main truss should form the rails. It might look strange; but we are here speaking of strength; and evident, but not unwieldy strength, when once it becomes familiar, is the surest source of beauty in all works of this kind.

43 How to distinguish bridges formed according to these different methods.

44 The best general form of a wooden bridge.

Centre of Friction, is that point in the base of a body on which it revolves; into which, if the whole surface of the base, and the mass of the body, were collected, and made to revolve about the centre of the base of the given body, the angular velocity destroyed by its friction would be equal to the angular velocity destroyed in the given body by its friction in the same time. See Friction in this Supplement.

Centre of Gyration, is that point in which, if the whole mass be collected, the same angular velocity will be generated in the same time, by a given force acting at any place, as in the body or system itself. This point differs from the centre of oscillation, in as much as in this latter case the motion of the body is produced by the gravity of its own particles; but, in the case of the centre of gyration, the body is put in motion by some other force acting at one place only.

Centre of Oscillation, is that point in the axis or line of suspension of a vibrating body, or system of bodies, in which, if the whole matter or weight be collected, the vibrations will still be performed in the same time, and with the same angular velocity, as before. Hence, in a compound pendulum, its distance from the point of suspension is equal to the length of a simple pendulum whose oscillations are isochronal with those of the compound one.

Centre of Pressure, of a fluid against a plane, is that point against which a force being applied equal and contrary to the whole pressure, it will just sustain it, so as that the body pressed on will not incline to either side.—This is the same as the centre of percussion, supposing the axis of motion to be at the intersection of this

this plane with the surface of the fluid; and the centre of pressure upon a plane parallel to the horizon, or upon any plane where the pressure is uniform, is the same as the centre of gravity of that plane.

CENTREVILLE, the chief town of Queen Ann's co. and on the E. side of Chesapeak bay in Maryland. It lies between the forks of Corsica creek, which runs into chester River and has been lately laid out; 18 miles S. of Chester; 34 S. E. by E. of Baltimore, and 95 S. W. by S. of Philadelphia. N. lat. 39. 6.—*Morse.*

CENTROBARICO, the same as centre of gravity.

CENTROBARIC METHOD, is a method of determining the quantity of a surface or solid, by means of the generating line or plane and its centre of gravity. The doctrine is chiefly comprised in this theorem:

Every figure, whether superficial or solid, generated by the motion of a line or plane, is equal to the product of the generating magnitude and the path of its centre of gravity, or the line which its centre of gravity describes.

CERUSE, or WHITE-LEAD, is a substance so much used in painting, and for other purposes, that numerous modes have been employed for the preparation of it. Of the most common of these, a sufficient account has been given in the Encyclopædia (see CERUSE, and the same word CHEMISTRY-*Index)*; but Lord Dundonald has discovered a more expeditious and facile method than any of them, which becomes the more useful, as the substance with which it is effected has been hitherto rejected by the chemical world as a *caput mortuum*.

His lordship directs common lead to be reduced to a calx, but not too fine, and to have a proportion of five-sixth parts thereof, intimately mixed with muriate, or solution of potass. In this state, he directs it to be frequently stirred, in order to have the new surfaces of the mixture exposed to the carbonic acid of atmospheric air; as his lordship observes, that the effects of the carbonic acid on the alkali existing in the present state of the mixture is essentially necessary, in order to effect the intended purpose. In this state, it is to be frequently sprinkled with water; and, after the calx has been long enough immersed with the muriate to be sufficiently operated upon, the muriate is to be levigated by common water from the calx, and to be concentrated by evaporation, in order to be made use of at a future period with other calx. The calx is to be afterwards ground, levigated, and dried for use.

For this discovery, his lordship obtained a patent on the 18th of August 1797; and the success which has attended the former patents of this scientific nobleman leads us to conclude, that the present discovery is entitled to the attention of the public.

CHACTAWS, or flat heads, are a powerful, hardy, subtile and intrepid race of Indians, who inhabit a very fine and extensive tract of hilly country, with large and fertile plains intervening, between the Alabama and Mississippi rivers, and in the western part of the state of Georgia. This nation had, not many years ago, 43 towns and villages, in three divisions, containing 12,123 souls, of which 4,041 were fighting men. They are called by the traders Flatheads, all the males having the fore and hind part of their skulls artificially flattened when young. These men, unlike the Muscogulges, are slovenly and negligent in every part of their dress, but otherwise are said to be ingenious, sensible, and virtuous men, bold and intrepid, yet quiet and peaceable. Some late travellers, however, have observed that they pay little attention to the most necessary rules of moral conduct, at least that unnatural crimes were too frequent among them. Different from most of the Indian nations bordering on the United States, they have large plantations or country farms, where they employ much of their time in agricultural improvements, after the manner of the white people. Although their territories are not ⅓th so large as those of the Muscogulge confederacy, the number of inhabitants is greater. The Chactaws and Creeks are inveterate enemies to each other.—*Morse.*

CHAGRE, a river and town in Terra Firma, S. America. The river opens to the N. Sea, and was formerly called Lagortas, from the number of alligators in it; has its source in the mountains near Cruces, and its mouth is in N. lat. 9. where there is a strong fort, built on a steep rock, on the E. side, near the sea shore. This fort has a commandant, and lieutenant, and the garrison is draughted from Panama, to which you go by this river, landing at Cruces, about 5 leagues from Panama, and thence one travels by land to that city. Opposite to fort Chagre is the royal custom-house. Here the river is broadest, being 120 toises over; whereas, at Cruces, where it begins to be navigable, it is only 20 toises wide; from the town of Chagre, to the mouth of the river, is 21 miles N. W. by W. but measuring by water is 43 miles. There is at Cruces an alcalde, who lives at the custom-house, and takes an account of all goods on the river. Chagre fort was taken by admiral Vernon, in 1740.—*ib.*

CHAMBERS (Sir William), the celebrated architect, was descended of the ancient family of Chalmers in Scotland, barons of Tartas, in France. His grandfather suffered considerably in his fortune by supplying Charles XII. of Sweden with money, &c. which that monarch repaid in base coin. Sir William's father resided several years in Sweden to recover his claims; and there Sir William was born, and, at eighteen years of age, appointed supercargo to the Swedish East India company. From a voyage which he made to China, he brought home the Asiatic style of ornament, in tents, temples, mosques, and pagodas. These ornaments (through the interest of lord Bute) he was enabled to apply in the gardens at Kew. Patronised by the princess dowager and the king, Mr Chambers had much of the fashionable business of the day. Under Burke's reform, he was appointed surveyor-general of the board of works. Somerset-house was worth to him at least £.2000 a year. His *Chef d'œuvres* are his staircases, particularly those at Lord Besborough's, Lord Gower's, and the Royal and Antiquarian Societies. The terrace behind Somerset house is a bold effort of conception. His designs for interior arrangements were excellent. His Treatise on Civil Architecture alone will immortalize his name. In private life, Sir William was hospitable, kind, and amiable. His son married Miss Rodney; Mr Cotton, Mr Innis, and Mr Harward, married his beautiful daughters. Having been abstemious in his youth, Sir William's constitution did not begin to break till he was seventy years of age. For the last three years, he was kept alive by wine and oxygenated air; and died on the 5th of March 1796. His celebrity will be lasting in the works which he has left; and, as he was equally skilled in the theory and practice of the arts which he professed, his precepts are as valuable as his works. At his death, he was fellow of the Royal and Antiquarian Societies, treasurer of the Royal Academy, surveyor-general of the board of works, and knight of the Swedish order of the Polar Star.

CHAMBERSBURG, a post town, in Pennsylvania, and the chief of Franklin co. It is situated on the eastern branch of Conogocheague creek, a water of Potowmac River in a rich and highly cultivated country, and healthy situation.—Here are about 200 houses, 2 Presbyterian churches, a stone gaol, a handsome court-house, built of brick, a paper and merchant mill. It is 58 miles E. by S. of Bedford, 11 N. W. of Shippensburg, and 157 W. of Philadelphia. N. lat. 39. 53. W. long. 77. 30.—*Morse*.

CHAMBLEE *River* or *Sorell*, a water of the St Lawrence, issuing from lake Champlain, 300 yards wide when lowest. It is shoal in dry seasons; but of sufficient breadth for rafting lumber, &c. spring and fall. It was called both Sorell and Richlieu when the French held Canada.—*ib*.

Chamblee *Fort*, is handsome and well built, on the margin of the river of the same name, about 12 or 15 miles S. W. from Montreal, and N. of St John's fort. It was taken by the Americans, Oct. 20, 1775, and retaken by the British, Jan. 18, 1776. N. lat. 45. 45.—*ib*.

CHAMFER, or Chamferet, an ornament, in architecture, consisting of half a scotia; being a kind of small furrow or gutter on a column.

CHAMPLAIN, a lake next in size to lake Ontario, and lies E. N. E. from it, forming a part of the dividing line between the states of New-York and Vermont. It took its name from a French governor, who was drowned in it. It was before called Corlaer's Lake. Reckoning its length from Fairhaven to St John's, a course nearly N. it is about 200 miles; its breadth is from 1 to 18 miles, being very different in different places; the mean width is about 5 miles; and it occupies about 500,000 acres. Its depth is sufficient for the largest vessels. There are in it above sixty islands of different sizes; the most considerable are North and South Hero, and Motte island. North Hero, or Grand Isle, is 24 miles long and from 2 to 4 wide. It receives at Ticonderoga the waters of Lake George from the S. S. W. which is said to be 100 feet higher than the waters of this lake. Half the rivers and streams which rise in Vermont fall into it. There are several which come to it from New-York state and some from Canada; to which last it sends its own waters, a N. course, through Soreil or Chamblee river, into the St Lawrence. This lake is well stored with fish; particularly salmon, salmon-trout, sturgeon and pickerel; and the land on its borders, and on the banks of its rivers, is good.

The rocks in several places appear to be marked, and stained, with the former surface of the lake, many feet higher than it has been since its discovery in 1608. The waters generally rise from about the 20th of April, to the 20th of June, from 4 to 6 feet; the greatest variation is not more than 8 feet. It is seldom entirely shut up with ice, until the middle of January. Between the 6th and 15th of April the ice generally goes off; and it is not uncommon for many square miles of it to disappear in one day.—*Morse*.

Champlain, a township the most northerly in Clinton co. New-York, which takes its name from the lake on which it lies. It was granted to some Canadian and Nova-Scotia refugees, who were either in the service of the United States, during the war, or fled to them for protection. The indigence or ill habits of these people occasioned the breaking up of the settlement; and a better set of inhabitants have now taken their place. The lands are fertile; and two rivers run through it, well stored with fish. It has 575 inhabitants, and 3 slaves. By the state census of 1796, 76 of the inhabitants are electors.—*ib*.

CHAPPE (Jean d'Auteroche), a French astronomer, was born at Mauriac, in Auvergne, March 2. 1728. A taste for drawing and mathematics appeared in him at a very tender age; and he owed to Dom Germain a knowledge of the first elements of mathematics and astronomy. M. Cassini, after assuring himself of the genius of this young man, undertook to improve it. He employed him upon the map of France, and the translation of Halley's tables, to which he made considerable additions. The king charged him in 1753 with drawing the plan of the county of Bitche, in Lorraine, all the elements of which he determined geographically. He occupied himself greatly with the two comets of 1760; and the fruit of his labour was his elementary treatise on the theory of those comets, enriched with observations on the zodiacal light, and on the aurora borealis. He soon after went to Tobolsk, in Siberia, to observe the transit of Venus over the sun; a journey which greatly impaired his health. After two years absence he returned to France in 1762, where he occupied himself for some time in putting in order the great quantity of observations he had made. M. Chappe also went to observe the next transit of Venus, viz. that of 1769, at California, on the west side of North America, where he died of a dangerous epidemic disease, the 1st of August 1769. He had been named adjunct astronomer to the academy the 17th of January 1759.

The published works of M. Chappe, are, 1. The Astronomical Tables of Dr Halley, with Observations and Additions, in 8vo, 1754. 2. Voyage to California, to Observe the Transit of Venus over the Sun, the 3d of June 1769; in 4to, 1772. 3. He had a considerable number of papers inserted in the Memoirs of the Academy, for the years 1760, 1761, 1764, 1765. 1766, 1767, and 1768; chiefly relating to astronomical matters.

CHAPPEL-HILL, a post town in Orange co. N. Carolina, situated on a branch of Newhope creek, which empties into the N. W. branch of Cape Fear River. This is the spot chosen for the seat of the University of North-Carolina. Few houses are as yet erected; but a part of the public buildings were in such forwardness, that students were admitted, and education commenced in Jan. 1796. The beautiful and elevated scite of this town commands a pleasing and extensive view of the surrounding country; 12 miles S. by E. of Hillsborough, and 472 S. W. of Philadelphia. N. lat. 35. 40. W. long. 79. 6.—*ib*.

Universal CHARACTERS, could they be introduced, Characters.

duced, would contribute ſo much to the diffuſion of uſeful knowledge, that every attempt to make ſuch a ſcheme ſimple and practicable is at leaſt entitled to notice. Accordingly, in the *Encyclopædia*, under the word CHARACTER, a ſhort account is given of the principal plans of univerſal characters which had then fallen under our obſervation; but ſince that article was publiſhed, a new method of writing, by which the various nations of the earth may communicate their ſentiments to each other, has been propoſed by *Thomas Northmore*, Eſq; of Queen-ſtreet, Mayfair. It bears ſome reſemblance to that which we have given from the *Journal Literaire*, 1720, but it is not the ſame; and of the two, Mr Northmore's is perhaps the moſt ingenious. The ground-work of the ſuperſtructure differs not indeed from that of the journaliſt, being this in both, "That if the ſame numerical *figure* be made to repreſent the *ſame word* in the various languages upon earth, an univerſal character is immediately obtained." The only objection which our author or his friends ſaw to ſuch a plan, originates in the diverſity of idioms; but, as he truly obſerves, every ſchoolboy has this difficulty to encounter as often as he conſtrues Terence.

Such then was Mr Northmore's original plan: but he ſoon perceived that it was capable of conſiderable improvement; for, inſtead of uſing a figure for *every* word, it will be neceſſary to apply one only to every *uſeful* word; and we all know how few words are abſolutely neceſſary to the communication of our thoughts. Even theſe may be much abbreviated by the adoption of certain *uniform fixed* ſigns (not amounting to above 20), for the various caſes, numbers, genders, degrees of compariſon, of nouns, tenſes, and moods, of verbs, &c. All words of negation, too, may be expreſſed by a prefixed ſign. A few inſtances will beſt explain the author's meaning.

Suppoſe the number	5	to repreſent the word	*ſee*,
	6	— —	*a man*,
	7	— —	*happy*,
	8	— —	*never*,
	9	— —	*I*.

"I would then (ſays he) expreſs the tenſes, genders, caſes, &c. *in all languages*, in ſome ſuch *uniform* manner as following:

(1)	5	=	*preſent tenſe*, —	ſee,
(2)	.5	=	*perfect tenſe*, —	ſaw,
(3)	:5	=	*perfect participle*, —	ſeen,
(4)	5:	=	*preſent participle*, —	ſeeing,
(5)	5·	=	*future*, — —	will ſee,
(6)	$\underline{5}$	=	*ſubſtantive*, —	ſight,
(7)	$\underline{\underline{5}}$	=	*perſonal ſubſtantive*, —	ſpectator,
(8)	$\dot{6}$	=	*nominative caſe*, —	a man,
(9)	$\ddot{6}$	=	*genitive*, — —	of a man,
(10)	$\dddot{6}$	=	*dative*, — —	to a man,
(11)	$\overset{\frown}{6}$	=	*feminine*, — —	a woman,
(12)	+6	=	*plural*, — —	men,
(13)	7	=	*poſitive*, — —	happy,
(14)	$\hat{7}$	=	*comparative*, —	happier,
(15)	$\hat{\hat{7}}$	=	*ſuperlative*, —	happieſt,
	$\underline{7}$	=	as above, N° 6. —	happineſs,
(16)	—7	=	*negation*, — —	unhappy,

"From the above ſpecimen, I ſhould find no difficulty in comprehending the following ſentence, though it were written in the language of the Hottentots: 9, 8, .5, —$\hat{7}$, $\overset{\frown}{6}$. *I never ſaw a more unhappy woman.*

"Thoſe languages which do not uſe the pronoun prefixed to the verb, as the Greek and Roman, &c. may apply it, in a ſmall character, ſimply to denominate the perſon; thus, inſtead of 9, 8, .5, *I never ſaw;* they may write, 8, $_{9}$.5, which will ſignify that the verb is in the firſt perſon, and will ſtill have the ſame meaning."

Our author ſeems confident that, according to this ſcheme of an univerſal character, about 20 ſigns, and leſs than 10,000 *choſen* words (ſynonyms being ſet aſide), would anſwer all the ends propoſed; and that foreigners, by referring to their numerical dictionary, would eaſily comprehend each other. He proceeds next to ſhew how appropriate ſounds may be given to his ſigns, and an univerſal *living language* formed from the univerſal *characters*.

To attain this end, he propoſes to diſtinguiſh the ten numerals by ten monoſyllabic names of eaſy pronunciation, and ſuch as may run without difficulty into one another. To illuſtrate his ſcheme, however, he calls them for the preſent, by their common Engliſh names; but would pronounce each number made uſe of by uttering ſeparately its component parts, after the manner of accountants. Thus let the number 6943 repreſent the word *horſe*, he would not, in the univerſal language, call a horſe *ſix thouſand nine hundred and forty three*, but *ſix, nine, four, three*, and ſo on for all the words of a ſentence, making the proper ſtop at the end of each. In the ſame manner, a diſtinct appellation muſt be appropriated to each of the prefixed ſigns, to be pronounced immediately after the numeral to which it is an appendage. Thus if *plu* be the appellation or the ſign of the plural number, *ſix, nine, four, three, plu* will be *horſes*.

"Thus (ſays our author), I hope, it is evident that about 30 or 40 diſtinct ſyllables are ſufficient for the above purpoſe; but I am much miſtaken if *eleven* only will not anſwer the ſame end. This is to be done by ſubſtituting the firſt 20 or 30 numerals for the ſigns, and ſaying, as in algebra, that a term is in the power of ſuch a number, which may be expreſſed by the ſimple word *under*. *Ex. gr.* Let 6943 repreſent the word *horſe;* and ſuppoſe 4 to be the ſign of the plural number, I would write the word thus, $\frac{4}{6943}$; and pronounce it, ſix, nine, four, three, in the power of or *under* four. By theſe means eleven diſtinct appellations would be ſufficient, and time and uſe would much abbreviate the pronunciation."

To refuſe the praiſe of ingenuity to this contrivance for an univerſal language would be very unjuſt; but elocution in this manner would be ſo very tedious, that ſurely the author himſelf, when he thinks more coolly on the ſubject, will perceive, that in the living ſpeech its defects would more than balance its advantages. A *pangraph*, as he calls his univerſal character, would indeed

deed be ufeful, and is certainly practicable; a *pavleg* (if we may form fuch a word) would not be very ufeful, unlefs it were much more perfect than it could be made according to the plan before us.

CHARLES *River* in Maffachufetts, called anciently *Quinobequin*, is a confiderable ftream, the principal branch of which rifes from a pond bordering on Hopkinton. It paffes through Hollifton and Bellingham, and divides Medway from Medfield, Wrentham, and Franklin, and thence into Dedham, where, by a curious bend, it forms a peninfula of 900 acres of land. A ftream called Mother Brook, runs out of this river in this town, and falls into Neponfit River, forming a natural canal, uniting the two rivers, and affording a number of excellent mill-feats. From Dedham the courfe of the river is northerly, dividing Newton from Needham, Wefton, and Waltham, paffing over romantic falls; it then bends to the N. E. and E. through Watertown and Cambridge, and paffing into Bofton harbor, mingles with the waters of Myftic River at the point of the peninfula of Charleftown. It is navigable for boats to Watertown, 7 miles. The moft remarkable bridges on this river are thofe which connect Bofton with Charleftown and Cambridge. There are 7 paper mills on this river, befides other mills. —*Morse.*

Charles *Co.* on the weftern fhore of Maryland, lies between Potowmack and Patuxent rivers. Its chief town is Port Tobacco, on the river of that name. Its extreme length is 28 miles, its breadth 24, and it contains 20,613 inhabitants, including 10,085 flaves. The country has few hills, is generally low and fandy, and produces tobacco, Indian corn, fweet potatoes, &c. —*ib.*

Charles City *Co.* in Virginia, lies between Chickahominy and James rivers. It contained formerly part of what now forms Prince George's co. It has 5588 inhabitants, including 3141 flaves.—*ib.*

Charles, a cape of Virginia, in about N. lat. 37. 15. It is on the N. fide of the mouth of Chefapeak bay, having Cape Henry oppofite to it.—*ib.*

Charles, a cape on the S. W. part of the ftrait entering into Hudfon Bay. N. lat. 62. 40. W. long. 75. 15.—*ib.*

CHARLESTON, a diftrict in the Lower country of S. Carolina, fubdivided into 14 parifhes. This large diftrict, of which the city of Charlefton is the chief town, lies between Santee and Combahee rivers. It pays £.21,473-14-6 fterling taxes. It fends to the ftate legiflature 48 reprefentatives and 13 fenators, and 1 member to Congrefs. It contains 66986 inhabitants, of whom, only 16352 are free.—*ib.*

Charleston, the metropolis of S. Carolina, is the moft confiderable town in the ftate; fituated in the diftrict of the fame name, and on the tongue of land formed by the confluent ftreams of Afhley and Cooper, which are fhort rivers, but large and navigable. Thefe waters unite immediately below the city, and form a fpacious and convenient harbor; which communicates with the ocean juft below Sullivan's Ifland; which it leaves on the N. 7 miles S. E. of Charlefton. In thefe rivers the tide rifes, in common, about 6½ feet; but uniformly rifes 10 or 12 inches more during a night-tide. The fact is certain; the caufe unknown. The continual agitation which the tides occafion in the waters which almoft furround Charlefton—the refrefhing fea-breezes which are regularly felt, and the fmoke arifing from fo many chimneys, render this city more healthy than any part of the low country in the fouthern ftates. On this account it is the refort of great numbers of gentlemen, invalids from the W. India iflands, and of the rich planters from the country, who come here to fpend the fickly months, as they are called, in queft of health and of the focial enjoyments which the city affords. And in no part of America are the focial bleffings enjoyed more rationally and liberally than here. Unaffected hofpitality—affability—eafe of manners and addrefs—and a difpofition to make their guefts welcome, eafy and pleafed with themfelves, are characteriftics of the refpectable people of Charlefton. In fpeaking of the capital, it ought to be obferved, for the honour of the people of Carolina in general, that when in common with the other colonies, in the conteft with Britain, they refolved againft the ufe of certain luxuries, and even neceffaries of life; thofe articles, which improve the mind, enlarge the underftanding, and correct the tafte, were excepted; the importation of books was permitted as formerly.

The land on which the town is built, is flat and low, and the water brackifh and unwholefome. The ftreets are pretty regularly cut, and open beautiful profpects, and have fubterranean drains to carry off filth and keep the city clean and healthy; but are too narrow for fo large a place and fo warm a climate. Their general breadth is from 35 to 66 feet. The houfes which have been lately built, are brick, with tiled roofs. The buildings in general are elegant, and moft of them are neat, airy and well furnifhed. The public buildings are, an exchange, a ftate-houfe, an armoury, a poor-houfe, and an orphan's houfe. Here are feveral refpectable academies. Part of the old barracks has been handfomely fitted up, and converted into a college, and there are a number of ftudents; but it can only be called as yet a refpectable academy. Here are two banks—a branch of the national bank, and the S. Carolina bank, eftablifhed in 1792. The houfes for public worfhip are two epifcopal churches, two for Independents, one for Scotch Prefbyterians, one for Baptifts, one for German Lutherans, two for Methodifts, one for French Proteftants, a meeting-houfe for Quakers, a Roman Catholic chapel, and a Jewifh fynagogue.

Little attention is paid to the public markets; a great proportion of the moft wealthy inhabitants having plantations from which they receive fupplies of almoft every article of living. The country abounds with poultry and wild ducks. Their beef, mutton and veal are not generally of the beft kind; and few fifh are found in the market.

In 1787, it was computed that there were 1600 houfes in this city, and 15,000 inhabitants, including 5,400 flaves; and what evinces the healthinefs of the place, upwards of 200 of the white inhabitants were above 60 years of age. In 1791, there were 16,359 inhabitants, of whom 7684 were flaves. This city has often fuffered much by fire, the laft and moft deftructive happened as late as June, 1796.

Charlefton was incorporated in 1783, and divided into three wards, which chofe as many wardens, from among whom the citizens elect an intendant of the city. The intendant and wardens form the city-council, who have power to make and enforce bye-laws for the regulation of the city.

The value of exports from this port, in the year ending Nov. 1787, amounted to £.505,279-19-5 sterling. The number of vessels cleared from the custom-house the same year, was 947, measuring 62,118 tons; 735 of these, measuring 41,531 tons, were American; the others belonged to Great-Britain, Ireland, Spain, France, and the United Netherlands. In the year 1794, the value of exports amounted to 3,846,392 dollars. It is 60 miles S. W. by S. of Georgetown; 150 E. by S. of Augusta; 497 S. by W. of Richmond; 630 S. W. by S. of Washington city; 763 S. W. by S. of Philadelphia; and 1110 S. W. of Boston. The light-house lies in N. lat. 32. 41. 52. White Point at the S. end of the town, N. lat. 32. 44. 30. W. long. 80. 39. 45.

Knoxville, the capital of the state of Tennessee, is much nearer to this than to any sea-port-town on the Atlantic Ocean. A waggon road of only 15 miles is wanted to open the communication; and the plan is about to be executed by the state.—*ib.*

CHARLESTOWN, a post-town in Cecil co. Maryland, near the head of Chesapeak bay; 6 miles E. N. E. from the mouth of Susquehannah River; 10 W. S. W. from Elkton, and 50 S. W. by W. from Philadelphia. Here are about 20 houses, chiefly inhabited by fishermen employed in the herring fishery. N. lat. 39. 34.—*ib.*

CHARLESTOWN, a township in Montgomery co. New-York, on the S. side of Mohawk river, about 32 miles W. of Schenectady. By the state census of 1796, 456 of the inhabitants are electors.—*ib.*

CHARLESTOWN, a township in Mason co. Kentucky; situated on the Ohio at the mouth of Lauren's creek. It contains but few houses, and is 6 miles N. of Washington, and 60 N. E. of Lexington. N. lat. 38. 43. —*ib.*

CHARLESTOWN, a township in Chester co. Pennsylvania.—*ib.*

CHARLESTOWN, a post-town in Cheshire co. New-Hampshire, on the E. side of Connecticut River 30 miles S. of Dartmouth College; upwards of 70 N. of Northampton, 116 N. of W. of Boston, 80 W. by N. of Portsmouth, and 341 N. N. E. of Philadelphia. It was incorporated in 1753, and contains 90 or 100 houses, a Congregational church, a court-house and an academy. The road from Boston to Quebec passes through this town. N. lat. 43. 16. W. long. 72. 19. A small internal trade is carried on here.—*ib.*

CHARLESTOWN, the principal town in Middlesex co. Massachusetts, called *Mishawun* by the aboriginal inhabitants, lies N. of Boston, with which it is connected by Charles-River Bridge. The town, properly so called, is built on a peninsula, formed by Mystic River on the E. and a bay, setting up from Charles-River, on the W. It is very advantageously situated for health, navigation, trade, and manufactures of almost all the various kinds. A dam across the mouth of the bay, which sets up from Charles-River, would afford a great number of mill-seats for manufactures. Bunker's, Breed's, and Cobble (now Barrell's) hills, are celebrated in the history of the American Revolution. The second hill has upon its summit a monument erected to the memory of major gen. Warren, near the spot where he fell, among the first sacrifices to American liberty. The brow of the hill begins to be ornamented with elegant houses. All these hills afford elegant and delightful prospects of Boston, and its charmingly variegated harbor, of Cambridge and its colleges, and of an extensive tract of highly cultivated country. It contains within the neck or parish about 250 houses, and about 2000 inhabitants. The only public buildings of consequence are a handsome Congregational church, with an elegant steeple and clock, and an alms-house, very commodious and pleasantly situated.

Before the destruction of this town by the British in 1775, several branches of manufactures were carried on to great advantage, some of which have been since revived; particularly the manufacture of pot and pearl ashes, ship-building, rum, leather in all its branches, silver, tin, brass, and pewter. Three rope-walks have lately been erected in this town, and the increase of its houses, population, trade, and navigation, have been very great within a few years past. This town is a port of entry in conjunction with Boston. At the head of the neck there is a bridge over Mystic River which connects Charlestown with Malden.—*ib.*

CHARLESTOWN, a village in Berkley co. Virginia, situated on the great road leading from Philadelphia to Winchester; 8 miles from Shepherdstown, and 20 from Winchester.

CHARLESTOWN, a township in Washington co. Rhode-Island state, having the Atlantic ocean on the southward, and separated from Richmond on the northward by Charles-river, a water of Pawcatuck. Some of its ponds empty into Pawcatuck River, others into the sea. It is 19 miles N. W. of Newport, and contains 2022 inhabitants, including 12 slaves.

A few years ago there were about 500 Indians in the state; the greater part of them resided in this township. They are peaceable and well disposed to government, and speak the English language.—*ib.*

CHARLESTOWN, the only town in the island of Nevis, one of the Caribbees, belonging to Great-Britain. In it are large houses and well furnished shops, and it is defended by Charles fort. In the parish of St John, on the S. side of the town, is a large spot of sulphureous ground, at the upper end of a deep chasm in the earth, commonly called Sulphur Gut, which is so hot as to be felt through the soles of one's shoes. A small hot river, called the Bath, is thought to proceed from the said gut; and after running half a mile, loses itself in the sands of the sea. Black-Rock pond, about a quarter of a mile N. from the town, is milk-warm, owing to the mixture of hot and cold springs, yet it yields excellent fish; particularly fine eels, silver fish, and slim-guts. A prodigious piece of Nevis mountain falling down in an earthquake, several years ago, left a large vacuity, which is still to be seen. The altitude of this mountain, taken by a quadrant from Charlestown bay, is said to be a mile and a half perpendicular; and from the said bay to the top, four miles. The declivity from this mountain to the town is very steep half way, but afterwards easy of ascent. N. lat. 16. 55. W. long. 62. 42.—*ib.*

CHARLESTOWN, or *Oftins*, one of the four principal towns in the island of Barbadoes.—*ib.*

CHARLETON *Island*, or *Charles Island*, is situated at the bottom of James's bay, in New South Wales, on on the coast of Labrador, and yields a beautiful prospect, in spring, to those who are near it, after a voyage of 3 or 4 months in the most uncomfortable seas on the globe, and that by the vast mountains of ice in Hudson bay and straits. The whole island, spread with trees and branches, exhibits, as it were, a beautiful green tuft. The air even at the bottom of the bay, though in 51 degrees, a latitude nearer the sun than London, is excessively cold for nine months, and very hot the other three, except on the blowing of a N. W. wind. The soil on the E. side, as well as the W. bears all kinds of grain; and some fruits, gooseberries, strawberries, and dewberries, grow about Rupert's bay. N. lat. 52. 30. W. long. 82.—*ib.*

Charleton, a township in Saratoga co. New-York. By the state census of 1796, 268 of its inhabitants were electors.—*ib.*

Charleton, a township in Worcester co. Massachusetts, incorporated in 1754, and until then, formed the westerly part of Oxford. It is 60 miles S. W. of Boston, 15 S. W. of Worcester, and contains 1965 inhabitants. Quincbaugh River forms some of its rich intervale lands, and furnishes excellent mill seats for this, and many adjacent towns.—*ib.*

CHARLOTTE *Fort*, in S. Carolina, is situated on the point of land where Tugeloo and Broad rivers, uniting their waters, form Savannah River. According to Bartram, it is one mile below Fort James, Dartmouth. N. lat. 34. W. long. 82. 35.—*ib.*

Charlotte *Haven*, lies at the mouth of Charlotte River in E. Florida; having Carlos bay on the S. and Rock Point on the northward. N. lat. 27. W. long. 82. 40. Charlotte River is fed by Spiritu Santo Lagoon, which communicates, by Delaware River with Chatham or Punjo bay, which is 90 miles S. E. from Charlotte Haven.—*ib.*

Charlotte, a considerable township on the E. side of Lake Champlain, and the S. westernmost in Chittenden co. Vermont. Shelburne on the N. separates this town from Burlington. It contains 635 inhabitants. Split Rock, in Lake Champlain, lies off this town.

Charlotte *Co.* in Virginia, lies S. W. of Richmond, on the head waters of Staunton River, and contains 10,078 inhabitants, including 4,816 slaves. The court-house is 21 miles S. S. W. of Prince Edward court-house, and 379, about the same course, from Philadelphia.—*ib.*

Charlotteburg, a town in Brunswick co. N. Carolina. It stands on an island, and has an inlet and sound of the same name, a little S. of it.—*ib.*

Charlotte, or *Charlottesville*, a post-town in Salisbury district, N. Carolina, and chief town of Mecklenburg co. situated on Steel creek, which joins the Sugaw, and falls into Catabaw River about 10 miles N. of the S. Carolina boundary, and 44 S. of Salisbury. Here are about 40 houses, a court-house and gaol. —*ib.*

Charlottesville, the capital of Albemarle co. in Virginia, lies on the post road from Richmond to Danville, in Kentucky, 86 miles W. N. W. of the former, and 557 eastward of the latter, and 40 S. E. by E. of Staunton. It contains about 45 houses, a court-house and a goal, situated about half a mile N. from a water of Rivanna river.—*ib.*

Charlotte *Town*, the capital of the island of St John's, in the gulf of St Lawrence. Also, the name of a town on the S. W. side of the island of Dominica, in the W. Indies; and situated on the S. side of a deep bay.—*ib.*

CHARLOTIA, a town on the E. shore of St John's River, East Florida, where that river is about half a mile wide. It was founded by Den. Rolle, Esq. and is situated on a high bluff, 15 or 20 feet perpendicular from the river; and is in length half a mile, or more. The aborigines of America had a very great town in this place, as appears from the great tumuli and conical mounts of earth and shells, and other traces of a settlement which yet remain. The river, for near 12 miles above Charlotia, is divided into many channels by a number of islands.—*ib.*

CHARTRES, a fort which was built by the French, on the eastern side of the Mississippi, 3 miles northerly of *La Praire du Rocher*, or the Rock Meadows, and 12 miles northerly of St Genevieve, on the western side of that river. It was abandoned in 1772, being untenable by the constant washings of the Mississippi in high floods. The village southward of the fort was very inconsiderable in 1778. A mile above this is a village settled by 170 warriors of the Piorias and Mitchigamias tribes of Illinois Indians, who are idle and debauched.—*ib.*

CHATHAM, a maritime township in Barnstable co. Massachusetts, situated on the exterior extremity of the elbow of Cape Cod, conveniently for the fishery; in which they have usually about 40 vessels employed. It has 1140 inhabitants, and lies 95 miles S. E. of Boston.—*ib.*

Chatham, a township in Grafton co. New-Hampshire. It was incorporated in 1767, and in 1790 contained 58 inhabitants.—*ib.*

Chatham, a flourishing township in Middlesex co. Connecticut, on the eastern bank of Connecticut River and opposite Middleton city. It was a part of the township of Middleton till 1767.—*ib.*

Chatham, a township in Essex co. N. Jersey, is situated on Passaic River, 13 miles W. of Elizabethtown, and nearly the same from Newark.—*ib.*

Chatham, a township in Columbia co. New-York. By the state census of 1796, 380 of its inhabitants were electors.—*ib.*

Chatham *Co.* in Hillsborough district, N. Carolina, about the centre of the state. It contains 9221 inhabitants, of whom 1632 are slaves. Chief town, Pittsburg. The court-house is a few miles W. of Raleigh, on a branch of Cape Fear river.—*ib.*

Chatham, a town of S. Carolina, in Cheraws district, situated in Chesterfield co. on the W. side of Great Pedee River. Its situation, in a highly cultivated and rich country, and at the head of a navigable river, bids fair to render it a place of great importance. At present it has only about 30 houses, lately built.—*ib.*

Chatham *Co.* in the lower district of Georgia, lies in the N. E. corner of the state, having the Atlantic ocean E. and Savannah river N. E. It contains 10,769 inhabitants, including 8,201 slaves. The chief town is Savannah, the former capital of the state.—*ib.*

Chatham, or *Punjo bay*, a large bay on the W. side of the S. end of the promontory of E. Florida. It receives North and Delaware rivers.—*ib.*

CHATHAM *Houfe*, in the territory of the Hudfon bay company, N. lat. 55. 23. 40. W. long. from Greenwich 98.—*ib.*

CHATA-HATCHI, or *Hatchi*, is the largeft river which falls into St Rofe's bay in W. Florida. It is alfo called Pea river, and runs from N. E. entering the bottom of the bay through feveral mouths; but fo fhoal that only a fmall boat or canoe can pafs them. Mr Hutchins afcended this river about 25 leagues, where there was a fmall fettlement of Couffac Indians. The foil and timber on the banks of the river refemble very much thofe of Efcambia.

CHATAUCHE, or *Chatahuthe*, a river in Georgia. The northern part of Appalachicola river bears this name. It is about 30 rods wide, very rapid, and full of fhoals. The lands on its banks are light and fandy, and the clay of a bright red. The Lower Creeks are fettled in fcattering clans and villages from the head to the mouth of this river. Their huts and cabins, from the high colour of the clay, refemble clufters of new-burned brick kilns. The diftance from this river to the Talapoofe River is about 70 miles, by the war-path, which croffes at the falls, juft above the town of the Tuckabatches.—*ib.*

CHATAUGHQUE *Lake*, in Ontario co. New-York, is about 18 miles long, and 3 broad. Conewango River which runs a S. S. E. courfe, connects it with Alleghany River. This lake is conveniently fituated for a communication between lake Erie and the Ohio; there being water enough for boats from fort Franklin on the Alleghany to the N. W. corner of this lake; from thence there is a portage of 9 miles to Chataughque harbor on lake Erie, over ground capable of being made a good waggon road. This communication was once ufed by the French.—*ib.*

CHAUMETTE (Pierre Gafparine), though a man of talents and an author, would hardly have deferved a place in this work, did not his life and the manner of his death hold out an awful warning againft thofe principles which produced the overthrow of focial order in France.

He was a native of the town of Nevers, in the Orleanois; and as he rofe to the office of recorder in Paris, few men excited more attention in France for a time, or had a more hateful tafk to perform, during the moft tragical part of the revolution, than Chaumette. He had been bred to the fea; but not relifhing that life, and failing to obtain expected preferment therein, he quitted it, and lived by the ufe of his pen, which he certainly knew how to manage more to his profit than the compafs. He could, however, fpeak better, and more fluently, than he could write. He had alfo been employed as a librarian and amanuenfis to a dignitary of the church, in the diocefe of Nivernois; but at the commencement of the troubles in France, he was actually a clerk to an attorney, and occafionally wrote for the newfpapers, as well as trifles for the ftage. He was one of the chief difciples of Camille Defmoulins, and among the firft who put the tri-coloured cockade in his hat juft before the taking of the Baftille. He greatly out-ran that apoftle in zeal for the new faith; for when Camille was compofing the firft number of his *Vieux Cordelier*, with the hope of tranquillifing the overheated imaginations of the leaders of that great event, and tempering the public rage againft the real or fuppofed enemies of the new order of things, Chaumette was ftill farther inflaming it, and directing it in vengeance againft particular individuals. It was Chaumette that inftigated the commune of Paris to demand the trial of the queen, and he was of the committee which prepared the charges and regulated the evidence againft that ill-fated woman. He was himfelf a witnefs too againft her at the revolutionary tribunal, and undertook to reprimand M. la Tour Dupin, lately war minifter to Louis XVI. for not expofing thofe parts of Antoinette's conduct, which, it was infifted on, he was privy to or acquainted with.

The moft infamous part of Chaumette's conduct on that occafion was his accufing the queen of an inceftuous connection with her fon. Even the horrid tribunal was fhocked at this infinuation, of which the author became inftantly the object of almoft univerfal abhorrence; and Robefpierre himfelf, under whofe aufpices Chaumette was believed to act, grew outrageous when he was told of a charge fo fcandaloufly abfurd. "The fool (exclaimed he) was it not enough that he had proved her a Meffalina, but he muft make her an Agrippina too!" Of proof indeed there was not much; and the fevereft enemy of the beautiful Antoinette, if his mind be not wholly warped by prejudice, will admit, that by thefe brethren in iniquity fhe was murdered under the form of a revolutionary trial.

Robefpierre had fenfe enough to fee that this abominable conduct of Chaumette would hurt the caufe in which they were both embarked; and for that reafon he never forgave him, though he allowed the zeal to continue to operate on inferior objects, till it whelmed the zealot himfelf in ruin. Chaumette had credit now with none but the very *fcum* of the revolution; and fuch recrementitious matter will always be thrown off in national ebullitions of this kind.

Robefpierre was at this time in the very zenith of his power, yet Chaumette moved fuch a propofition in the full commune, as gave reafon to many to believe that he would fet up as his rival in the city. This daring motion was for uniting all the heads of the 48 fections of Paris in one council; a meafure that would have fuperfeded the force of the legiflature itfelf, if not its authority. This was a project, conceived in common with the famous Hebert, Momora, and Mazuel, and would have been aided in its execution by the daring Roufin, who at that time commanded a body of the *armeé revolutionaire*.

How far Robefpierre was apprifed of or approved the fcheme, does not appear; many fhrewd obfervers of what was paffing, feemed fatisfied that it was to have been only a prelude "to the fwelling act" that was to follow, when the hero of the piece was to have been in full play. The majority of the convention faw through the veil which covered the workings of the plot, and anticipated their own danger, fhould it be carried into effect. They, therefore, without lofs of time, annulled the proceedings already had in it, and declared all to be rebels who fhould perfift therein. Chaumette appeared to put a good face on the correction. He told the commune, on its next meeting, that his propofition muft be relinquifhed; for that the convention, with a voice paternal, though fevere, had ftamped with nullity

nullity their former resolution, and that it became them, like dutiful children, to submit. Hebert, Momora, and Mazuel, were soon after accused as traitors, imprisoned, tried, and executed; but Chaumette survived a short time longer, as his enemies thought it safer to wear away by degrees the remaining popular partiality for him, before he should be struck at. He was taken up, however, on the 26th of March 1794, under a charge of conspiring, with the foregoing men, against the government, and guillotined on the 13th of April following, without the smallest effort on the part of Robespierre, to save him. Such is the gratitude and such the friendship of minds filled with universal philanthropy and the rights of man! That Chaumette and Robespierre were closely linked together, is known to all who are not strangers to the transactions of that time; but when the latter had risen to dictatorial power on the shoulders of the former, he kicked him, like an useless scaffold, from under his feet.

Chaumette said at the place of execution, that the revolution had inflamed his imagination, and at times intoxicated his brain, from the too free gratification of his vengeance for the personal injuries he had received. He said also, that three instances had come to light of his aristocratic and inveterate enemies attempting his life; and that a desire of reprisal, in which he conceived the safety of the commonwealth in a measure involved, made him seek all occasions for arrogating power; but that he never cherished an idea of possessing any permanent authority, not even of a secondary or subordinate nature. That the revolution intoxicated his brain, is doubtless true; but that he never aspired to permanent authority, is an infamous falsehood.

CHAUSETRAPPES. See *Crow's Feet*, Encycl.

CHEAT *River*, rises in Randolph co. Virginia, and after pursuing a N. N. W. course, joins Monongahela River, 3 or 4 miles within the Pennsylvania line. It is 200 yards wide at its mouth, and 100 yards at the Dunkards settlement, 50 miles higher, and is navigable for boats except in dry seasons. There is a portage of 37 miles from this River to the Potowmack at the mouth of Savage river.—*Morse*.

CHEGOMEGAN, a point of land about 60 miles in length, on the S. side of lake Superior. About 100 miles W. of this cape, a considerable River falls into the lake; upon its banks abundance of virgin copper is found.—*ib*.

CHELMSFORD, a township in Middlesex co. Massachusetts, situated on the S. side of Merrimack River 26 miles N. westerly from Boston, and contains 1144 inhabitants. There is an ingeniously constructed bridge over the River at Pawtucket Falls, which connects this town with Dracut. The route of the Middlesex canal, designed to connect the waters of Merrimack with those of Boston harbor, will be southerly through the E. part of Chelmsford.—*ib*.

CHELSEA, called by the ancient natives *Winnisimet*, a town in Suffolk co. Massachusetts, containing 472 inhabitants. Before its incorporation, in 1738, it was a ward of the town of Boston. It is situated northeasterly of the metropolis, and separated from it by the ferry across the harbor, called Winnisimet.—*ib*.

CHELSEA, a township in Orange co. Vermont, having 239 inhabitants.—*ib*.

CHELSEA, the name of a parish in the city of Norwich (Connecticut) called the Landing, situated at the head of the river Thames, 14 miles N. of New-London, on a point of land formed by the junction of Shetucket and Norwich, or Little rivers, whose united waters constitute the Thames. It is a busy, commercial, thriving, romantic, and agreeable place, of about 150 houses, ascending one above another in tiers, on artificial foundations, on the south point of a high, rocky hill.—*ib*.

CHEMIN DES RONDS, in fortification, the way of the rounds, or a space between the rampart and the low parapet under it, for the rounds to go about it.

CHEMISTRY,

1 Definition. IS a science, the object of which is to ascertain the ingredients that enter into the composition of bodies, to examine the nature of these ingredients, the manner in which they combine, and the properties resulting from their combination.

As an art, it has been in some measure coeval with the human race; for many of the most important branches of manufactures could not have been conducted without at least some knowledge of chemical combinations. As a science, it can hardly be dated farther back than the middle of the 17th century; but since that time it has advanced with a rapidity altogether unprecedented in the annals of philosophy. Newton laid its foundation; and since his days an almost incredible number of the most distinguished names in Europe have enlisted under its banners. So rapid has this progress been, that though the article CHEMISTRY in the *Encyclopædia* was written only about ten years ago, the language and reasoning of chemistry have been so greatly improved, and the number of facts have accumulated so much, that we find ourselves under the necessity of tracing over again the very elements of the science.

2 Importance of chemistry. Indeed, if we consider the importance of chemistry, we shall not be so much surprised at the ardour with which it has been cultivated. As a science, it is intimately connected with all the phenomena of nature; the causes of rain, snow, hail, dew, wind, earthquakes; even the changes of the seasons can never be explored with any chance of success while we are ignorant of chemistry; and the vegetation of plants, and some of the most important functions of animals, have received all their illustration from the same source. No study can give us more exalted ideas of the wisdom and goodness of the Great First Cause than this, which shews us everywhere the most astonishing effects produced by the most simple though adequate means, and displays to our view the great care which has every where been taken to secure the comfort and happiness of every living creature. As an art, it is intimately connected with

Oxygen. with all our manufactures: The glass-blower, the potter, the smith, and every other worker in metals, the tanner, the soap-maker, the dyer, the bleacher, are really practical chemists; and the most essential improvements have been introduced into all these arts by the progress which chemistry has made as a science. Agriculture can only be improved rationally, and certainly by calling in the assistance of chemistry; and the advantages which medicine has derived from the same source are too obvious to be pointed out.

3 Arrangement. It is evident from the definition of chemistry that it must consist in a history of the simple substances which enter into the composition of bodies, in an investigation of the manner in which these substances combine, and in a description of the properties of the compounds which they form. And this is the arrangement which we mean to pursue; reserving to ourselves, however, the liberty of deviating a little from it, whenever it may appear necessary for the sake of perspicuity. All our classifications are in fact artificial; nature does not know them, and will not submit to them. They are useful, however, as they enable us to learn a science sooner, and to remember it better; but if we mean to derive these advantages from them, we must renounce a rigid adherence to arbitrary definitions, which nature disclaims. Oxygen.

We shall begin by an account of the simplest bodies, and proceed gradually to those which are more compound. By *simple bodies*, we do not mean what the ancient philosophers called the *elements of bodies*, but merely substances, which have not yet been decompounded. Very possibly the bodies which we reckon simple may be real compounds; but till this has actually been proved, we have no right to suppose it. Were we acquainted with all the elements of bodies, and with all the combinations of which these elements are capable, the science of chemistry would be as perfect as possible; but at present this is very far from being the case.

We shall divide this article into four parts. The *first* part shall treat of those bodies which are at present considered as simple; the *second*, of those bodies which are formed by the union of two simple bodies, and which for want of a better word we shall call *compound bodies*; the *third*, of those bodies which are formed by the union of two compound bodies; and the *fourth*, of bodies such as they are presented to us by nature in the mineral, vegetable, and animal kingdoms.

PART I. OF SIMPLE BODIES. (1)

4 Classes of simple bodies. ALL the bodies which are at present reckoned simple, because they have never been decompounded, may be reduced into six classes.

1. Oxygen,	4. Earths,
2. Simple combustibles,	5. Caloric,
3. Metals,	6. Light.

These shall form the subjects of the six following chapters.

CHAP. I. *Of* OXYGEN.

Plate XVIII. TAKE a quantity of nitre, or saltpetre as it is also called, and put it into a gun barrel A (fig. 1.), the touch-hole of which has been previously closed up with

5 Method of procuring oxygen. metal. This barrel is to be bent in such a manner, that while the close end, in which the nitre lies, is put into the fire E, the open end may be plunged below the surface of the water, with which the vessel B is filled. At the same time, the glass jar, D, previously filled with water, is placed on the support C, lying at the bottom of the vessel of water B, so as to be exactly over the open end of the gun barrel A. As soon as the nitre becomes hot, it emits a quantity of air, which issuing from the end of the gun barrel, ascends to the top of the glass jar D, and gradually displaces all the water. The glass jar D then appears to be empty, but is in fact filled with air. It may then be removed in the following manner; Slide it away a little from the gun barrel and the support, and then dipping any flat dish into the water below it, raise it on it, and bear it away. The dish must be allowed to retain a quantity of water in it, (see fig. 2.) Another jar may then be filled with air in the same manner; and this process may be continued either till the nitre ceases to give out air, or till as many jarfuls have been obtained as are required. This method of obtaining and confining air was first invented by Dr Mayow, and afterwards much improved by Dr Hales. All the airs obtained by this or any other process, or, to speak more properly, all the airs differing from the air of the atmosphere, have, in order to distinguish them from it, been called *gases*, and this name we shall afterwards employ.

The gas which we have obtained by the above process was discovered by Dr Priestley on the 1st of August 1774, and called by him *dephlogisticated air*. Mr Scheele of Sweden discovered it in 1775, without any previous knowledge of what Dr Priestley had done: he gave it the name of *empyreal air*. Condorcet, so conspicuous during the French revolution, gave it first the name of *vital air*; and Mr Lavoisier afterwards called it *oxygen gas*; a name which is now generally received, and which we shall adopt. 6 Discovered by Priestley and Scheele.

Oxygen gas may be obtained likewise by the following process:

D (in fig. 3.) represents a wooden trough, the inside of which is lined with lead or tinned copper. AB is a shelf running along the inside of it, about three inches from the top. C is the cavity of the trough, which ought to be a foot deep. It is to be filled with water at least an inch above the shelf AB In the body of the trough, which may be called the cistern, the jars destined to hold gas are to be filled with water, and then to be lifted, and placed inverted upon the shelf at B, with 7 Another method.

(1) The writer of the notes signed T. P. S. considers himself responsible for no other errors contained in this system of chemistry than those contained in his own notes. From a number of circumstances he was under the necessity of reading this work so cursorily, that probably many deductions which on more mature consideration he might have objected to, may have passed unnoticed. T. P. S.

Oxygen. with their edges a little over it. This trough, which was invented by Dr Prieſtley, has been called by the French chemiſts the *pneumato chemical*, or ſimply *pneumatic* apparatus, and is extremely uſeful in all experiments in which gaſes are concerned. Into the glaſs veſſel E put a quantity of the black oxyd (A) of manganeſe in powder, and pour over it as much of that liquid which in commerce is called *oil of vitriol*, and in chemiſtry *ſulphuric acid*, as will ſomewhat more than cover it. Then inſert into the mouth of the veſſel the glaſs tube F, ſo cloſely that no air can eſcape except through the tube. This may be done by covering the joining with a paſte made of wheat flour and water, or any other *lute*, as ſubſtances uſed for ſimilar purpoſes are called. The end of the tube C is then to be plunged into the pneumatic apparatus D and the jar G, previouſly filled with water, to be placed over it on the ſhelf. The whole apparatus being fixed in that ſituation, the glaſs veſſel E is to be heated by means of a lamp or a candle. A great quantity of oxygen gas ruſhes along the tube F, and fills the jar G. As ſoon as the jar is filled, it may be ſlid to another part of the ſhelf, and other jars ſubſtituted in its place, till as much gas has been obtained as is wanted.

8 Properties of oxygen.

1. Oxygen gas is colourleſs, and inviſible like common air. Like it too, it is elaſtic, and capable of indefinite expanſion and compreſſion.

9 Supports flame,

2. If a lighted taper be let down into a jar of oxygen gas, it burns with ſuch ſplendor that the eye can ſcarcely bear the glare of light, and at the ſame time produces a much greater heat than when burning in common air. It is well known that a candle put into a well cloſed jar filled with common air is extinguiſhed in a few ſeconds. This is the caſe alſo with a candle incloſed in oxygen gas; but it burns much longer in an equal quantity of that gas than of common air.

10 And life.

3. It was proved long ago by Boyle, that animals cannot live without air, and by Mayow that they cannot breathe the ſame air for any length of time without ſuffocation. Dr Prieſtley and ſeveral other philoſophers have ſhewn us, that animals live much longer in the ſame quantity of oxygen gas than of common air. Count Morozzo placed a number of ſparrows, one after another, in a glaſs bell filled with common air, and inverted over water.

	H.	M.
The firſt ſparrow lived	3	0
The ſecond	0	3
The third	0	1

He filled the ſame glaſs with oxygen gas, and repeated the experiment.

	H.	M.
The firſt ſparrow lived	5	23
The ſecond	2	10
The third	1	30
The fourth	1	10
The fifth	0	30
The ſixth	0	47
The ſeventh	0	27
The eighth	0	30
The ninth	0	22
The tenth	0	21

He then put in two together; the one died in 20 minutes, but the other lived an hour longer.

11 Exiſts in the atmoſphere.

4. Atmoſpherical air contains about 27 parts in the hundred of oxygen gas. This was firſt diſcovered by Scheele. It has been proved by a great number of experiments, that no ſubſtance will burn in common air previouſly deprived of all the oxygen gas which it contained; but combuſtibles burn with great ſplendor in oxygen gas, or in other gaſes to which oxygen gas has been added. Oxygen gas, then, is abſolutely neceſſary for combuſtion.

5. It has been proved alſo, by many experiments, that no breathing animal can live for a moment in any air or gas which does not contain oxygen mixed with it. Oxygen gas then is abſolutely neceſſary for reſpiration.

6. When ſubſtances are burnt in oxygen gas, or in any other gas containing oxygen, if the air be examined after the combuſtion, a great part of the oxygen will be found to have diſappeared. If charcoal, for inſtance, be burnt in oxygen gas, there will be found, inſtead of part of the oxygen, another very different gas, known by the name of carbonic acid gas. Exactly the ſame thing takes place when air is reſpired by animals; part of the oxygen gas diſappears, and its place is occupied by ſubſtances poſſeſſed of very different properties. Oxygen gas then undergoes ſome change during combuſtion, as well as the bodies which have been burnt; and the ſame obſervation applies alſo to reſpiration (B).

12 Its ſpecific gravity.

7. The ſpecific gravity of oxygen gas, as determined by Mr Kirwan*, is 0,00135, that of water being 1,0000, as is always the caſe when ſpecific gravity is mentioned abſolutely. It is therefore 740 times lighter than the ſame bulk of water. Its weight to atmoſpherical air is as 1103 to 1000: 116 cubic inches of oxygen gas weigh 39,03 grains troy, 116 cubic inches of common air, 35,38 grains.

* On *Phlogiſton*, ſect. i.

13 *Affinity* explained.

8. Oxygen is capable of combining with a great number of bodies, and forming compounds. As the combination of bodies is of the utmoſt importance in chemiſtry,

(A) This ſubſtance ſhall be afterwards deſcribed. It is now very well known in Britain, as it is in common uſe with bleachers and ſeveral other manufacturers.

(B) Mayow had in the laſt century made conſiderable progreſs towards the diſcovery of oxygen gas. He knew that only a part of the air ſupported combuſtion: This part he called *particulæ igneo aereæ*. He knew that this part was contained in nitre: Pars nitri aerea nihil aliud quam particulæ ejus igneo-aereæ eſt." He adds, "At non eſt eſtimandum pabulum igneo-aereum ipſum aerem eſſe, ſed tantum partem ejus majus activam ſubtilemque. Quippe lucerna vitro incluſa expirat cum tamen copia aeris ſatis ampla in eodem continetur." He knew alſo that it was this part of the air which was uſeful in reſpiration. After mentioning ſeveral experiments to prove this, he adds, "Ex dictis certo conſtat animalia reſpirando particulas quaſdam vitales eaſque elaſticas ab aere haurire." See his *Tractatus quinque Medico-Phyſici*, p. 12. and 106.—He knew alſo that this part of the air was neceſſary to combuſtion: "Et tamen certo conſtat, particulas nitro-aereas non minus quam ſulphureas ad ignem conflandum neceſſareas eſſe." *Ibid.* p. 26.

Oxygen.

miſtry, before proceeding farther we ſhall attempt to explain it. When common ſalt is thrown into a veſſel of pure water, it melts, and very ſoon ſpreads itſelf through the whole of the liquid, as any one may convince himſelf by the taſte. In this caſe the ſalt is combined with the water, and cannot afterwards be ſeparated by filtration or any other method merely mechanical. It may, however, by a very ſimple proceſs: Pour into the ſolution a quantity of ſpirit of wine and the whole of the ſalt inſtantly falls to the bottom.

Why did the ſalt diſſolve in water, and why did it fall to the bottom on pouring in ſpirit of wine? Theſe queſtions were firſt anſwered by Sir Iſaac Newton. There is a certain attraction between the particles of common ſalt and thoſe of water, which cauſes them to unite together whenever they are preſented to one another. There is an attraction alſo between the particles of water and of ſpirit of wine, which equally diſpoſes them to unite, and this attraction is greater than that between the water and ſalt; the water therefore leaves the ſalt to unite with the ſpirit of wine, and the ſalt, being now unſupported, falls to the ground by its gravity. This power, which diſpoſes the particles of different bodies to unite, was called by Newton *attraction*, by Bergman, *elective attraction*, and by many of the German and French chemiſts, *affinity*; and this laſt term we ſhall employ, becauſe the other two are rather general. All ſubſtances which are capable of combining together are ſaid to have an *affinity for* (c) each other: thoſe ſubſtances, on the contrary, which do not unite, are ſaid to have *no affinity* for each other. Thus there is no affinity between water and oil. It appears from the inſtance of the common ſalt and ſpirit of wine, that ſubſtances differ in the degree of their affinity for other ſubſtances, ſince the ſpirit of wine diſplaced the ſalt and united with the water. Spirit of wine therefore has a ſtronger affinity for water than common ſalt has.

In 1719 Geoffroi invented a method of repreſenting the different degrees of affinities in tables, which he called *tables of affinity*. His method conſiſted in placing the ſubſtances whoſe affinities were to be aſcertained at the top of a column, and the ſubſtances with which it united below it, each in the order of its affinity; the ſubſtance which had the ſtrongeſt affinity next it, and that which had the weakeſt fartheſt diſtant, and ſo of the reſt. According to this method, the affinity of water for ſpirit of wine and common ſalt would be marked as follows:

Water,
Spirit of wine,
Common ſalt,

This method has been univerſally adopted, and has contributed very much to the rapid progreſs of chemiſtry.

14
Affinities of oxygen.

We ſhall proceed therefore to give a table of the affinities of oxygen.

Oxygen,
Carbon,
Zinc,
Iron,
Manganeſe,
Hydrogen,
Azot,
Sulphur,
Phoſphorus,
Cobalt,
Nickel,
Lead,
Tin,
Phoſphorous acid,
Copper,
Biſmuth,
Antimony,
Mercury,
Silver,
Arſenic,
Sulphurous acid,
Oil,
Nitrous gas,
Gold,
White oxyd of arſenic,
Muriatic acid,
Oxyd of tin,
White oxyd of lead?
Nitrous acid,
White oxyd of manganeſe,
Water.

The reaſon of this order will appear when we treat of theſe various ſubſtances.

Oxygen
Sulphur.

Chap. II. *Of* Simple Combustible Bodies.

15
Five ſimple combuſtibles.

By *combuſtibles*, we mean ſubſtances capable of combuſtion; and by *ſimple combuſtibles*, bodies of that nature which have not yet been decompounded.(2) Theſe are only five in number, Sulphur, Phosphorus, Carbon, Hydrogen, and Azot. Were we to adhere ſtrictly to our definition indeed, we ſhould add all the metals; for they are alſo combuſtible, and have not yet been decompounded: But for the reaſons formerly given, we ſhall venture to deviate a little from ſtrict logic, and conſider them afterwards as a diſtinct claſs of ſubſtances.

Sect. I. *Of Sulphur.*

Sulphur, diſtinguiſhed alſo in Engliſh by the name of *brimſtone*, was known in the earlieſt ages. As it is found native in many parts of the world, it could not fail very ſoon to attract the attention of mankind. It was uſed by the ancients in medicine, and its fumes were employed in bleaching wool.*

Sulphur

* *Pliny*, lib. xxxv. c. 15.

(c) We are not certain that the phraſe *affinity for* is warranted by claſſical authority; we have ventured, however, to uſe it, becauſe, as the word *affinity* in this article ſignifies a ſpecies of attraction, we thought it would be more perſpicuous to put after it the prepoſition *for*, which uſually follows the word *attraction*, than *to* or *with*, which come after *affinity* when uſed in its ordinary acceptation.

(2) A more correct definition of combuſtibles, according to our *preſent* knowledge relative to this claſs of bodies, would be, a ſubſtance which has a ſtronger affinity for oxygen than *light* and *caloric* have. T. P. S.

Sulphur.

16
Properties of sulphur.

Sulphur is a hard brittle ſubſtance, commonly of a yellow colour, without any ſmell, and of a weak though perceptible taſte.

It is a non-conductor of electricity, and of courſe becomes electric by friction.

If a conſiderable piece of ſulphur be expoſed to a ſudden though gentle heat, by holding it in the hand, for inſtance, it breaks to pieces with a crackling noiſe†.

† *Fourcroy.*

Its ſpecific gravity is 1,990.

When heated to the temperature of 185° of Fahrenheit, it melts and becomes very fluid. If the temperature be ſtill farther increaſed, the fluidity diminiſhes; but when the ſulphur is then carried from the fire and allowed to cool, it becomes as fluid as ever before it congeals‡.

‡ *Dr Black.*

When ſulphur is heated to the temperature of 170°, it riſes up in the form of a fine powder, which may be eaſily collected in a proper veſſel. This powder is called *flowers of ſulphur.* When ſubſtances fly off in this manner on the application of a moderate heat, they are called *vola'ile;* and the proceſs itſelf, by which they are raiſed, is called *volatilization.*

17
Flowers of ſulphur.

Sulphur undergoes no change by being allowed to remain expoſed to the open air.

When thrown into water, it does not melt, as common ſalt does, but falls to the bottom, and remains there unchanged; it is therefore *inſoluble* in water. If, however, it be poured, while in a ſtate of fuſion, into water, it aſſumes a red colour, and retains ſuch a degree of ſoftneſs, that it may be kneaded between the fingers; but it loſes this property in a few days*.

* *Fourcroy.*

18
Sulphur capable of cryſtallizing.

There are a great many bodies which, after being diſſolved in water or melted by heat, are capable of aſſuming certain regular figures. If a quantity of common ſalt, for inſtance, be diſſolved in water, and that fluid, by the application of a moderate heat, be made to fly off in the form of ſteam; or, in other words, if the water be ſlowly *evaporated,* the ſalt will fall to the bottom of the veſſel in cubes. Theſe regular figures are called *cryſtals.* Now ſulphur is capable of cryſtallizing. If it be melted, and as ſoon as its ſurface begins to congeal, the liquid ſulphur beneath be poured out, the internal cavity will exhibit long needle-ſhaped cryſtals of an octahedral figure. This method of cryſtallizing ſulphur was contrived by Rouelle.

19
Converted by combuſtion into an acid.

When ſulphur is heated to the temperature of 302° in the open air, it takes fire ſpontaneouſly, and burns with a pale blue flame, and at the ſame time emits a great quantity of fumes of a very ſtrong ſuffocating odour. When heated to the temperature of 570°, or a little higher, it burns with a bright white flame, and at the ſame time emits a vaſt quantity of fumes. If the heat be continued long enough, the ſulphur burns all away without leaving any aſhes or *reſiduum.* If the fumes be collected, they are found to conſiſt entirely of *ſulphuric acid.* By combuſtion, then, ſulphur is converted into an acid. This fact was known ſeveral centuries ago, but no intelligible explanation was given of it till the time of Stahl. That chemiſt undertook the taſk; and founded on his experiments a theory ſo exceedingly ingenious, and ſupported by ſuch a vaſt number of facts, that it was in a very ſhort time adopted with admiration by all the philoſophic world, and contributed not a little to raiſe chemiſtry to that rank among the ſciences from which the ridiculous pretenſions of the early chemiſts had excluded it.

20
Stahl's explanation of this

According to Stahl, there is only one ſubſtance in nature capable of combuſtion, which therefore he called Phlogiston; and all thoſe bodies which can be ſet on fire contain leſs or more of it. Combuſtion is merely the ſeparation of this ſubſtance. Thoſe bodies which contain none of it are of courſe incombuſtible. All combuſtibles, except thoſe which conſiſt of pure phlogiſton (if there be any ſuch), are compoſed of an incombuſtible body and phlogiſton united together. During combuſtion the phlogiſton flies off, and the incombuſtible body remains behind. Now when ſulphur is burnt, the ſubſtance which remains is ſulphuric acid, an incombuſtible body. Sulphur therefore is compoſed of ſulphuric acid and phlogiſton.

To eſtabliſh this theory completely, it was neceſſary to ſhew that ſulphur could be actually made by combining ſulphuric acid and phlogiſton; and this alſo Stahl undertook to perform. *Sulphat of potaſs* is a ſubſtance compoſed of ſulphuric acid and potaſs (D), and *charcoal* is a combuſtible body, and therefore, according to the theory of Stahl, contains phlogiſton: when burnt, it leaves a very inconſiderable reſiduum, and conſequently contains hardly any thing elſe than phlogiſton. He melted together in a crucible a mixture of *potaſs* and *ſulphat of potaſs,* ſtirred into it one-fourth part by weight of pounded charcoal, covered the crucible with another inverted over it, and applied a ſtrong heat to it. He then allowed it to cool, and examined its contents. The charcoal had diſappeared, and there only remained in the crucible a mixture of potaſs and ſulphur combined together, and of a darker colour than uſual, from the reſiduum of the charcoal. Now there were only three ſubſtances in the crucible at firſt, potaſs, ſulphuric acid, and charcoal: two of theſe have diſappeared, and *ſulphur* has been found in their place. Sulphur then muſt have been formed by the combination of theſe two. But charcoal conſiſts of phlogiſton and a very ſmall reſiduum, which is ſtill found in the crucible. The ſulphur then muſt have been formed by the combination of ſulphuric acid and phlogiſton. This ſimple and luminous explanation appeared ſo ſatisfactory, that the compoſition of ſulphur was long conſidered as one of the beſt demonſtrated truths in chemiſtry.

21
Unſatisfactory.

There are two facts, however, which Stahl either did not know or did not ſufficiently attend to, neither of which were accounted for by his theory. The firſt is, that ſulphur will not burn if air be completely excluded; the ſecond, that ſulphuric acid is heavier than the ſulphur from which it was produced.

To account for theſe, or facts ſimilar to theſe, ſucceeding chemiſts refined upon the theory of Stahl, deprived his phlogiſton of *gravity,* and even aſſigned it a principle of *levity.* Still, however, the neceſſity of the contact of air remained unexplained. At laſt Mr Lavoiſier, who had already diſtinguiſhed himſelf by the extenſiveneſs of his views, the accuracy of his experiments, and

(D) The nature of *potaſs* ſhall afterwards be explained. It is the *potaſh* well known in commerce in a ſtate of purity.

Sulphur.

and the precifion of his reafoning, undertook the examination of this fubject, and his experiments were publifhed in the Memoirs of the Academy of Sciences for 1777. He put a quantity of fulphur into a large glafs veffel filled with air, which he inverted into another veffel containing mercury, and then fet fire to the fulphur by means of a burning glafs. It emitted a blue flame, and gave out thick vapours, but was very foon extinguifhed, and could not be again kindled. There was, however, a little fulphuric acid formed, which was a good deal heavier than the fulphur which had difappeared; there was alfo a diminution in the air of the veffel proportional to this increafe of weight. The fulphur, therefore, during its converfion into an acid, muft have abforbed part of the air. He then put a quantity of fulphuret of iron, which confifts of fulphur and iron combined together, into a glafs veffel full of air, which he inverted over water (E). The quantity of air in the veffel continued diminifhing for eighteen days, as was evident from the afcent of the water to occupy the fpace which it had left; but after that period no farther diminution took place. On examining the fulphuret, it was found fomewhat heavier than when firft introduced into the veffel, and the air of the veffel wanted precifely the fame weight. Now this air had loft all its oxygen; all the oxygen of the air in the veffel muft therefore have entered into the fulphuret. Part of the fulphur was converted into fulphuric acid; and as all the reft of the fulphuret was unchanged, the whole of the increafe of weight muft have been owing to fomething which had entered into that part of the fulphur which was converted into acid. This fomething we know was oxygen. Sulphuric acid therefore muft be compofed of fulphur and oxygen; for as the original weight of the whole contents of the veffel remained exactly the fame, there was not the fmalleft reafon to fuppofe that any fubftance had left the fulphur.

22 Real explanation by Lavoifier.

It is impoffible, then, that fulphur can be compofed of fulphuric acid and phlogifton, as Stahl fuppofed; fince fulphur itfelf enters as a part into the compofition of that acid. There muft therefore have been fome want of accuracy in the experiment by which Stahl proved the compofition of fulphur, or at leaft fome fallacy in his reafonings; for it is impoffible that two contradictory facts can both be true. Upon examining the potafs and fulphur produced by Stahl's experiment, we find them to be confiderably lighter than the charcoal, fulphuric acid, and potafs originally employed. Something therefore has made its efcape during the application of the heat. And if the experiment be conducted in a clofe veffel, with a pneumatic apparatus attached to it, a quantity of gas will be obtained exactly equal to the weight which the fubftances operated on have loft; and this weight confiderably exceeds that of all the charcoal employed. This gas is *carbonic acid gas*, which is compofed of charcoal and oxygen, as will afterwards appear. We now perceive what paffes in this experiment: Charcoal has a ftronger affinity for oxygen at a high temperature than fulphur has. When charcoal therefore is prefented to fulphuric acid in that temperature, the oxygen of the acid combines with it, they fly off in the form of carbonic acid gas, and the fulphur is left behind.

Sulphur ‖ Phofphorus

The combuftion of fulphur, then, is nothing elfe than the act of its combination with oxygen; and, for any thing which we know to the contrary, it is a fimple fubftance.

23 Affinities of fulphur.

The affinities of fulphur, according to Bergman, are as follows:

Lead,
Tin,
Silver,
Mercury,
Arfenic,
Antimony,
Iron,
Fixed alkalies,
Ammonia,
Barytes,
Lime,
Magnefia,
Phofphorus?
Oils,
Ether,
Alcohol.

Sect. II. *Of Phofphorus.*

24 Production of phofphorus.

Let a quantity of bones be burnt, or, as it is termed in chemiftry, *calcined*, till they ceafe to fmoke, or to give out any odour, and let them afterwards be reduced to a fine powder. Put this powder into a glafs veffel, and pour fulphuric acid on it by little at a time, till farther additions do not caufe any extrication of air bubbles (F). Dilute the mixture with a good deal of water, agitate it well, and keep it hot for fome hours; then pafs it through a filtre. Evaporate the liquid flowly till a quantity of white powder falls to the bottom. This powder muft be feparated by filtration, and thrown away. The evaporation is then to be refumed; and whenever any white powder appears, the filtration muft be repeated in order to feparate it. During the whole procefs, what remains on the filtre muft be wafhed with pure water, and this water added to the liquor. The evaporation is to be continued till all the moifture difappears, and nothing but a dry mafs remains. Put this mafs into a crucible, and keep it melted in the fire till it ceafes to exhale fulphureous odours; then pour it out. When cold it affumes the appearance of a brittle glafs. Pound this glafs in a mortar, and mix it with one-third by weight of charcoal duft. Put this mixture into an earthen ware retort, and apply a receiver containing a little water. Put the retort into a fand bath, and increafe the fire till it becomes red hot. A fubftance then paffes into the receiver, which has the appearance of melted wax, and which congeals as it falls into the water of the receiver. This fubftance is *phofphorus*.

25 Its difcovery.

It was difcovered by Brandt, a chemift of Hamburgh, about the year 1667, while he was employed in attempting to extract from human urine, a liquid capable of converting filver into gold.*

* *Leibnitz, Melange de Berlin.*

Kunkel, another German chemift, hearing of the difcovery, was anxious to find out the procefs, and for that

(E) This experiment was firft made by Scheele, but with a different view.

(F) The copious emiffion of air bubbles is called in chemiftry *effervefcence*.

Phosphorus that purpose associated himself with a friend of his named Kraft. But the latter procured the secret from the discoverer; and expecting by means of it to acquire a fortune, refused to give any information to his associate. Vexed at this treachery, Kunkel resolved to attempt the discovery himself; and though he knew only that phosphorus was obtained from urine, prosecuted the inquiry with so much zeal, that he succeeded, and has been deservedly considered as one of the discoverers†.

† Stahl's Three Hundred Experiments.

Boyle likewise discovered phosphorus. Leibnitz indeed affirms that Kraft taught Boyle the whole process, and Kraft declared the same thing to Stahl. But surely the assertion of a dealer in secrets, and one who had deceived his own friend, on which the whole of this story is founded, cannot be put in competition with the affirmation of a man like Boyle, who was one of the honestest men, as well as greatest philosophers, of his age; and he positively assures us that he made the discovery, without being previously acquainted with the process‡.

‡ Boyle Abridged by Shaw, iii. 174.

Gahn, a Swedish chemist, discovered, in 1769, that phosphorus was contained in bones‖, and Scheele (G) very soon after invented a process for obtaining it from them. Phosphorus is now generally procured in that manner. The process described in the beginning of this section is that of the Dijon academicians: it differs from that of Scheele only in a single particular.

‖ Bergman's Notes on Scheffer.

26
Its properties.

Phosphorus, when pure, is of a clear, transparent, yellowish colour; but when kept some time in water, it becomes opaque, and then has a great resemblance to white wax. Its consistence is nearly that of wax: it may be cut with a knife, or twisted to pieces with the fingers. It is insoluble in water. Its specific gravity is 1,714.

It melts at the temperature of 99°*, and even at 67°* it gives out a white smoke, and is luminous in the dark; that is to say, it suffers a slow combustion: so that it can only be prevented from taking fire by keeping it in a very low temperature, or by allowing it to remain always plunged in water. If air be excluded, it evaporates at 219°, and boils at 554°†. When heated to 122° (H), it burns with a very bright flame, and gives out a great quantity of white smoke, which is luminous in the dark; at the same time it emits an odour which has some resemblance to that of garlic. It leaves no residuum; but when the white smoke is collected, it is found to be an *acid*. Stahl considered this acid as the muriatic (I). According to him, phosphorus was composed of muriatic acid and phlogiston, and the combustion of it was merely the separation of phlogiston. He even declared, that to make phosphorus, nothing more was necessary, than to combine muriatic acid and phlogiston; and that this composition was as easily accomplished as that of sulphur itself‡.

* Pelletier, Journal de Physique, xxxv. 380.

† Ibid. 381.

27
Converted by combustion

‡ Three Hundred Experiments.

These assertions gained implicit credit; and the composition and nature of phosphorus were considered as completely understood, till Margraf of Berlin published his experiments in the year 1743. That great man, one of those illustrious philosophers who have contributed so much to the rapid increase of the science, distinguished equally for the ingenuity of his experiments and the clearness of his reasoning, attempted to produce phosphorus by combining together phlogiston and muriatic acid; but though he varied his process a thousand ways, presented the acid in many different states, and employed a variety of substances to furnish phlogiston, all his attempts failed, and he was obliged to give up the combination as impracticable. On examining the acid produced during the combustion of phosphorus, he found that its properties were very different from those of muriatic acid. It was therefore a distinct substance. The name of *phosphoric acid* was given to it; and it was concluded that phosphorus was composed of this acid united to phlogiston.

28
Into phosphoric acid,

But it was observed in 1772 by Morveau*, that phosphoric acid was heavier than the phosphorus from which it was produced (K); and Boyle had long before shewn that phosphorus would not burn except when in contact with air. These facts were sufficient to prove the inaccuracy of the theory concerning the composition of phosphorus; but they remained themselves unaccounted for, till Lavoisier published those celebrated experiments, which threw so much light on the nature and composition of acids.

* Digress. Academ. p. 253.

He exhausted a glass globe of air by means of an air pump; and after weighing it accurately, he filled it with oxygen gas, and introduced into it 100 grains of phosphorus. The globe was furnished with a stop-cock, by which oxygen gas could be admitted at pleasure. He set fire to the phosphorus by means of a burning glass. The combustion was extremely rapid, accompanied by a bright flame and much heat. Large quantities of white flakes attached themselves to the inner surface of the globe, and rendered it opaque; and these at last became so abundant, that notwithstanding the constant supply of oxygen gas, the phosphorus was extinguished. The globe, after being allowed to cool, was again weighed before it was opened. The quantity of oxygen employed during the experiment was ascertained, and the phosphorus, which still remained unchanged, accurately weighed. The white flakes, which were nothing else than pure phosphoric acid, were found exactly equal to the weights of the phosphorus and oxygen which had disappeared during the process. Phosphoric acid therefore must have been formed by the combination of these two bodies; for the absolute weight of all the substances together was the same before and after the process*. It is impossible then that phosphorus can be composed of phosphoric acid and phlogiston,

29
Which is phosphorus combined with oxygen.

* Lavoisier's Chemistry, Part I. chap. v.

(G) Crell, in his life of Scheele, informs us, that Scheele was himself the discoverer of the fact. This, he says, clearly appears from a printed letter of Scheele to Gahn, who was before looked upon as the discoverer. See *Crell's Annals*, English Transf. I. 17.

(H) Morveau, *Enc. Method. Chimie*, art. *Affinité*—According to Nicholson at 160°. See his *Translation of Chaptal.*

(I) This acid shall be afterwards described.

(K) The same observation had been made by Margraf, but no attention was paid to it.

Phosphorus || Carbon.

phlogiston, as phosphorus itself enters into the composition of that acid(L).

Thus the combustion of phosphorus like that of sulphur, is nothing else than its combination with oxygen: for during the process no new substance appears except the acid, accompanied indeed with much heat and light.

30 Phosphorus combines with sulphur.

Phosphorus combines readily with sulphur, as Margraf discovered during his experiments on phosphorus. This combination was afterwards examined by Mr Pelletier. The two substances are capable of being mixed in different proportions. Seventy-two grains of phosphorus and nine of sulphur, when heated in about four ounces of water, melt with a gentle heat. The compound remains fluid till it be cooled down to 77°, and then becomes solid. These substances were combined in the same manner in the following proportions:

72 Phosphor. 18 Sulphur	congeals at	59°
72 Phosphor. 36 Sulphur	at	50°
72 Phosphor. 72 Sulphur	at	41°
72 Phosphor. 216 Sulphur	at	99°

Phosphorus and sulphur may be combined also by melting them together without any water; but the combination takes place so rapidly that they are apt to rush out of the vessel if the heat be not exceedingly moderate.†

† Pelletier, *Journ. de Phys.* xxxv. 382.

Phosphorus is capable of combining also with many other bodies: the compounds produced are called *phosphurets*.

The affinities of phosphorus have not yet been ascertained.

Sect. III. *Of Carbon.*

If a piece of wood be put into a crucible, well covered with sand, and kept red hot for some time, it is converted into a black shining brittle substance, without either taste or smell, well known under the name of *charcoal*. This substance contains always mixed with it several earthy and saline particles. When freed from these impurities it is called *carbon*.

31 Properties of carbon.

Charcoal is insoluble in water; it is not affected (provided that all air be excluded) by the most violent heat which can be applied, excepting only that it is rendered much harder.

New made charcoal absorbs moisture with avidity. When heated to a certain temperature, it absorbs air copiously. La Metherie plunged a piece of burning charcoal into mercury, in order to extinguish it, and introduced it immediately after into a glass vessel filled with common air. The charcoal absorbed four times its bulk of air. On plunging the charcoal in water, one-fifth of this air was disengaged. This air, on being examined, was found to contain a much smaller quantity of oxygen than atmospherical air does. He extinguished another piece of charcoal in the same manner, and then introduced it into a vessel filled with oxygen gas. The quantity of oxygen gas absorbed amounted to eight times the bulk of the charcoal; a fourth part of it was disengaged on plunging the charcoal into water*. It appears from the experiments of Sennebier, that charcoal, when exposed to the atmosphere absorbs oxygen gas in preference to *azot*†, as the other portion of common air is called.

* *Journ. de Phys.* xxx. 309.
† *Ann. de Chim.* iv. 261.

When heated to the temperature of 370°‡, it takes fire, and provided it has been previously freed from the earths and salts which it generally contains, it burns without leaving any residuum. If this combustion be performed in close vessels filled with oxygen gas instead of common air, part of the charcoal and oxygen disappear, and in their room is found a particular gas exactly equal to them in weight. This gas has the properties of an acid, and is therefore called *carbonic acid gas*. Mr Lavoisier, to whom we are indebted for this discovery, ascertained, by a number of very accurate experiments, that this gas was composed of about 28 parts of carbon and 72 of oxygen||.

‡ *Morveau, Encycl. Method.* art. *Affinité.*

32 Converted into an acid.

|| *Mem. Acad.* 1781, p. 448.

33 Susceptible of crystallization.

Carbon is susceptible of crystallization. In that state it is called *diamond*. The figure of the diamond varies considerably; but most commonly it is a hexagonal prism terminated by a six-sided pyramid. When pure it is colourless and transparent. Its specific gravity is from 3,44 to 3,55. It is one of the hardest substances in nature; and as it is not affected by a considerable heat, it was for many ages considered as incombustible. Sir Isaac Newton, observing that combustibles refracted light more powerfully than other bodies, and that the diamond possessed this property in great perfection, suspected, from that circumstance, that it was capable of combustion.(3) This singular conjecture was verified in 1694 by the Florentine academicians, in the presence of Cosmo III. grand duke of Tuscany. By means of a burning-glass, they destroyed several diamonds. Francis I. emperor of Germany, afterwards witnessed the destruction of several more in the heat of a furnace. These experiments were repeated by Rouelle, Macquer, and D'Arcet, who proved that the diamond was not merely evaporated, but actually burnt, and that if air was excluded it underwent no change.

No attempt, however, was made to ascertain the product, till Lavoisier undertook a series of experiments for that purpose in 1772. He obtained *carbonic acid gas*. It might be concluded from these experiments, that the diamond contains carbon; but it was reserved for Mr Tennant to show that it consisted entirely of that substance.

Into

(L) The quantity of phosphorus consumed was 45 grains
The quantity of oxygen gas - - - 69,375

Weight of the Phosphoric acid produced 114,375

Phosphoric acid therefore is composed of 100 parts phosphorus, and 154 oxygen.

(3) It were to be wished that some person provided with the proper apparatus would experiment on the *refractive* power of the gases, and ascertain if, according to Newton's theory, it bears any relation to their affinity for oxygen. T. P. S.

Carbon.

34 When it forms *diamond.*

Into a tube of gold, having one end cloſed and a glaſs tube adapted to the other to collect the product, that gentleman put $2\frac{1}{2}$ grains of diamonds and a quarter of an ounce of nitre (M). This tube was heated ſlowly; the conſequence of which was, that great part of the nitric acid paſſed off before the diamond took fire, and by that means almoſt the whole of the carbonic acid formed during the combuſtion of the diamond remained in the potaſs, for which it has a ſtrong affinity. To aſcertain the quantity of this carbonic acid, he diſſolved the potaſs in water, and added to the ſolution another ſalt compoſed of muriatic acid and lime. Muriatic acid has a ſtronger affinity for potaſs than for lime; it therefore combines with the potaſs, and at the ſame time the lime and carbonic acid unite and fall to the bottom of the veſſel, becauſe they are nearly inſoluble in water. He decanted off the liquor, and put the lime which contained the carbonic acid gas into a glaſs globe, having a tube annexed to it. This globe and tube he then filled with mercury, and inverted into a veſſel containing the ſame fluid. The lime by that means occupied the very top of the tube. It now remained to ſeparate the carbonic acid from the lime, which may be done by mixing it with any acid, as almoſt every other acid has a ſtronger affinity for lime than carbonic acid has. Accordingly on introducing muriatic acid, 10,3 ounce meaſures of carbonic acid gas, or nearly 9,166 grains, were ſeparated. But, according to the experiments of Lavoiſier, this gas is compoſed of 72 parts of oxygen and 28 of carbon; 9,166 grains therefore contain 2,56 grains of carbon, which is almoſt preciſely the weight of the diamond conſumed. It follows, therefore, that it was compoſed of pure carbon.* The difficulty of burning the diamond is owing entirely to its hardneſs. Meſſrs Morveau and Tennant rendered common charcoal ſo hard by expoſing it for ſome time to a violent fire in cloſe veſſels, that it loſt much of its natural tendency to combuſtion, and endured even a red heat without catching fire.†

* *Phil. Tranſ.* 1797, p. 123.

† *Encycl. Method. Chimie. art.* Acier.

Charcoal poſſeſſes a number of ſingular properties, which render it of conſiderable importance. It is incapable of putrefying or rotting like wood, and is not therefore liable to decay through age. This property has been long known. It was cuſtomary among the ancients to *char* the outſide of thoſe ſtakes which were to be driven into the ground or placed in water, in order to preſerve the wood from ſpoiling. New made charcoal, by being rolled up in cloths which have contracted a diſagreeable odour, effectually deſtroys it. It takes away the bad taint from meat beginning to putrefy, by being boiled along with it. It is perhaps the beſt teeth powder known. Mr Lowitz of Peterſburgh has ſhown, that it may be uſed with advantage to purify a great variety of ſubſtances.

35 Carburets.

Carbon unites with a number of bodies, and forms with them compounds known by the name of *carburets*. Its affinities have not yet been aſcertained.

Sect. IV. *Of Hydrogen.*

Hydrogen.

36 Method of procuring hydrogen.

Put into a glaſs veſſel furniſhed with two mouths a quantity of freſh iron filings, quite free from ruſt. Lute into one of theſe mouths the end of a crooked glaſs tube. Inſert the other end of this tube below a glaſs jar filled with water, and inverted into a pneumatic apparatus. Then pour upon the iron filings a quantity of ſulphuric acid, diluted with twice its own weight of water, and cloſe up the mouth of the veſſel. Immediately the iron filings and acid effervеſce with violence, a vaſt quantity of gas is produced, which ruſhes through the tube and fills the jar. This gas is called *hydrogen gas*.(N)

It was obtained by Dr. Mayow and by Dr Hales from various ſubſtances, and had been known long before in mines under the name of the *fire damp*. Mr Cavendiſh * was the firſt who examined its properties with attention. They were afterwards more fully inveſtigated by Prieſtley, Scheele, and Fontana.

* *Phil. Tran.* 1766.

37 Its properties.

Hydrogen, like *air*, is inviſible and elaſtic, and capable of indefinite compreſſion and dilatation.

Its ſpecific gravity differs according to its purity. Kirwan found it 0,00010†; Lavoiſier 0,000094‡, or about 12 times lighter than common air.

† *On Phlogiſton*, ſect. 1ſt.

‡ *Lavoiſier's Chemiſtry, Appendix.*

All burning ſubſtances are immediately extinguiſhed by being plunged into this gas. It is incapable therefore of ſupporting combuſtion.

Animals, when they are obliged to breathe it, die almoſt inſtantaneouſly. Scheele indeed found that he could breathe it for ſome time without inconvenience ‡; but Fontana, who repeated the experiment, diſcovered that this was owing to the quantity of common air contained in the lungs when he began to breathe; for on expiring as ſtrongly as poſſible before drawing in the hydrogen gas, he could only make three reſpirations, and even theſe three produced extreme feebleneſs and oppreſſion about the breaſt §.

‡ *Scheele on Fire.*

§ *Jour. de Phyſ.* xv. 99.

If a phial be filled with hydrogen gas, and a lighted candle be brought to its mouth, the gas will take fire, and burn gradually till it is all conſumed. If hydrogen and oxygen gas be mixed together and kindled, they burn inſtantaneouſly, and produce an exploſion like gunpowder. The ſame effect follows when a mixture of hydrogen gas and atmoſpherical air is kindled, but the exploſion is leſs violent. Hydrogen gas will not burn except in contact with oxygen gas, nor will it burn even in contact with oxygen gas, unleſs a red heat be applied to it. If 85 parts by weight of oxygen gas, and 15 of hydrogen gas, be mixed together, and ſet on fire in a cloſe veſſel, they diſappear, and in their place there is found a quantity of water exactly equal to them in weight. This water muſt be compoſed of theſe two gaſes; for it did not previouſly exiſt in the veſſel, and no other ſubſtance except the gaſes was introduced. Water then is compoſed of oxygen and hydrogen; and the combuſtion of hydrogen

38 Compoſition of water.

(M) Nitre is compoſed of potaſs and nitric acid; and nitric acid contains a great quantity of oxygen, which is eaſily ſeparated by heat. Diamond, when mixed with nitre, burns at a much lower heat than by any other proceſs.

(N) It was formerly called *inflammable air*, and by ſome chemiſts *phlogiſton*.

gen is nothing elſe but the act of its combination with oxygen (o).

It had been ſuppoſed, in conſequence of the experiments of Dr Prieſtley and ſeveral other philoſophers, that when hydrogen gas was allowed to remain in contact with water, it was gradually decompoſed, and converted into another gas; but Mr de Morveau,* Mr Haſſenfratz,† and Mr Libes,‡ have ſhewn, that it undergoes no change, provided ſufficient care be taken to exclude every other gas.

* *Encycl. Method. Chim.* i. 754
† *Ann. de Chim.* i. 92
‡ *Jour. de Phyſ.* xxxvi. 412.

Hydrogen gas diſſolves ſulphur, phoſphorus, and carbon. The compounds are called *ſulphurated*, *phoſphorated*, and *carbonated hydrogen gas*.

39 Compounds of hydrogen gas.

1. Sulphurated hydrogen gas was firſt examined with attention by Scheele, who, together with Bergman, diſcovered many of its properties. Mr Kirwan likewiſe publiſhed a very valuable paper on the ſame ſubject. If equal parts of ſulphur and potaſs be melted together in a covered crucible, they combine together, and form a compound known by the name of *ſulphuret of potaſs*, but formerly called, from its red colour, *hepar ſulphuris*, or *liver of ſulphur*. When this ſubſtance is moiſtened with water, it gives out a quantity of ſulphurated hydrogen gas; hence this gas was at firſt called *hepatic gas*.

40 Sulphurated hydrogen gas.

Mr Gengembre encloſed a bit of ſulphur in a glaſs veſſel filled with hydrogen gas, and melted the ſulphur by means of a burning glaſs. A quantity of it diſappeared, and the hydrogen aſſumed all the properties of *hepatic gas*. Hence it follows that this gas is merely ſulphur diſſolved in hydrogen gas.

The eaſieſt method of obtaining it is to pour an acid, the muriatic for inſtance, on a quantity of the ſulphuret reduced to powder. An effervеſcence takes place, the gas is extricated, and may be collected by means of a pneumatic apparatus. The theory of this emiſſion is obvious. The ſulphur is gradually converted into ſulphuric acid, by decompoſing the water, which is always united with acids, and ſeizing its oxygen: the hydrogen of the water is thus ſet at liberty; it aſſumes the gaſeous form, and at the ſame time diſſolves part of the remaining ſulphur, for which it has a conſiderable affinity.

The ſpecific gravity of ſulphurated hydrogen gas is 0,00135*; it is to common air as 1106 to 1000.

* *Kirwan on Phlogiſton* ſect. 1ſt.

It has a very fetid odour, preciſely ſimilar to that emitted by rotten eggs, which indeed is owing to the emiſſion of the very ſame gas.

It is not more reſpirable than hydrogen gas. When ſet on fire, in contact with oxygen gas, it burns with a light blue flame, without exploding, and at the ſame time a quantity of ſulphur is depoſited. The combuſtion of this gas, then, is merely the union of its hydrogen, and perhaps part of its ſulphur, with oxygen.

This gas turns ſyrup of violets to a green colour.* It does not ſeem capable of exiſting in atmoſpherical air without decompoſition; for the moment it comes into contact with oxygen gas, ſulphur is depoſited.†

* *Fourcroy's Chemiſtry, art.* Sulphur
† *Bergman.*

2. Phoſphorated hydrogen gas was diſcovered by Mr Gengembre in 1783, and by Mr Kirwan ſome time after, before he became acquainted with the experiments of that gentleman. It may be procured by mixing phoſphorus with potaſs diſſolved in water, and applying a boiling heat to the ſolution. The phoſphorus is gradually converted into an acid by decompoſing the water, and uniting with its oxygen. The hydrogen aſſumes the form of a gas, and flies off after diſſolving a little of the phoſphorus. This gas may be collected by means of a pneumatic apparatus.

41 Phoſphorated hydrogen gas.

Phoſphorated hydrogen gas has a ſmell reſembling that of putrid fiſh. When mixed with oxygen gas or common air, it becomes luminous; and on the application of the ſmalleſt heat, it burns with aſtoniſhing rapidity.‡ The products are water and phoſphoric acid. The combuſtion of this gas therefore is nothing elſe than the union of its phoſphorus and hydrogen with oxygen, attended by an emiſſion of heat and light.

‡ *Kirwan.*

Phoſphorated hydrogen gas may alſo be formed by introducing a bit of phoſphorus into a jar containing hydrogen gas; but care muſt be taken to make this gas as dry as poſſible; for its affinity with phoſphorus is weakened in proportion to its moiſture.‖

‖ *Brugnatelli, Nicholſon's Journal*, i. 445.

3. Carbonated hydrogen gas ariſes ſpontaneouſly in hot weather from marſhes, but always mixed with ſeveral other gaſes. Several ſpecies of it have been lately diſcovered by the aſſociated Dutch chemiſts Bondt, Dieman, Van Trooſtwyck, and Lauwerenberg.§ When 75 parts of ſulphuric acid and 25 of ſpirit of wine are mixed together, a gas is extricated which ſuffers no alteration from ſtanding over water. Its ſpecific gravity is 0,00111, or it is to common air as 909 to 1000. It has a fetid odour, and burns with a ſtrong compact flame. When paſſed through ſulphur it is converted into ſulphurated hydrogen gas, and at the ſame time a quantity of carbon is depoſited in the form of a fine powder; it muſt therefore be compoſed of carbon and hydrogen gas. When burnt, the product is carbonic acid

§ *Ann. de Chim.* xxxi. 48.

42 Carbonated hydrogen gas.

(o) The hiſtory of this great diſcovery, and the objections which have been made to it, we reſerve for the chapter which treats of *Water*, where they will be better underſtood than they could be at preſent. This ſubſtance was called *hydrogen* by the French chemiſts, becauſe it enters into the compoſition of water, from υδωρ *water*, and γινομαι *I am born*. Objections have been made to the propriety of the name, into which we ſhall not enter. It ought never to be forgotten, that Newton had long before, with a ſagacity almoſt greater than human, conjectured, from its great refracting power, that water *contained a combuſtible ſubſtance*. (4)

(4) That Newton *a-priori* from its refractive power ſhould have determined the *diamond* to be a *combuſtible* ſubſtance *may* reflect the higheſt credit on his genius. His determination of water containing an inflammable ſubſtance can however be conſidered but as a *lucky hit*. He aſcribed this inflammable principle to it on account of its great refractive power in proportion to its ſpecific gravity, the ſine of the angle of incidence being to the ſine of the angle of refraction in rock cryſtal 1.5620 to 1. and its gravity being 2.650 whereas in rain water whoſe ſpecific gravity is but 1. they bear the proportion of 1.3358 to 1. Had Newton applied this method of determining whether a ſubſtance contained an *inflammable principle* to other combinations of *oxygen* he would have fallen into groſs errors, in *ſulphuric acid*, for inſtance, whoſe ſpecific gravity is 2.125 the ſine of the angle of incidence is to that of refraction but as 1.4285 to 1. Hence he would have concluded that it contains *no inflammable* ſubſtance. T. P. S.

Hydrogen. * Ibid.

acid gas and water.* By making ether (P) pass thro' a red hot glass tube, another carbonated hydrogen gas was formed, the specific gravity of which was 0,00086. Spirit of wine, passed in the same manner, afforded a gas, the specific gravity of which was 0,00053, and which burned with a paler flame than the other two. These gases were found to contain from 80 to 74 parts of carbon, and from 20 to 26 of hydrogen. The first species was found to contain most carbon, and the last to contain least †.

† Ibid.

43 Affinities of these gases.

The affinity of hydrogen gas for these three combustibles is as follows:

Sulphur,
Carbon,
Phosphorus (Q).

Dr Austin found, that by repeatedly passing electric explosions through a small quantity of carbonated hydrogen gas, it was permanently dilated to more than twice its original bulk. He rightly concluded, that this remarkable expansion could only be owing to the evolution of hydrogen gas. On burning air thus expanded, he found that it required a greater quantity of oxygen than the same quantity of gas not dilated by electricity: An addition therefore had been made to the combustible matter; for the quantity of oxygen necessary to complete the combustion of any body, is always proportional to the quantity of that body. He concluded from these experiments, that he had decomposed the carbon which had been dissolved in the hydrogen gas; and that carbon was composed of hydrogen and azot (R), some of which was always found in the vessel after the dilated gas had been burnt by means of oxygen ‡. If this conclusion be fairly drawn, we must expunge *carbon* from the list of simple substances, and henceforth consider it as a compound.

44 Attempt to decompose carbon

‡ Phil. Transf. lxxx. 51.

45 Examined,

There was one circumstance which ought to have prevented Dr Austin from drawing this conclusion, at least till warranted by more decisive experiments. The quantity of combustible matter had been increased. Now, if the expansion of the carbonated hydrogen gas was owing merely to the decomposition of carbon, no such increase ought to have taken place, but rather the contrary; for the carbon, which was itself a combustible substance, was resolved into two ingredients, hydrogen and azot, only the first of which burnt on the addition of oxygen and the application of heat. Dr Austin's experiments have been lately repeated by Mr William Henry with a great deal of accuracy.* He found, that the dilatation which Dr Austin describes actually took place, but that it could not be carried beyond a certain degree, a little more than twice the original bulk of the gas. Upon burning separately by means of oxygen, two equal portions of carbonated hydrogen gas, one of which had been expanded by electricity to double its original bulk, the other not, he found that each of them produced precisely the same quantity of *carbonic acid gas*. Both therefore contained the same quantity of carbon; consequently no carbon had been decompounded by the electric shocks.

Azot. * Phil. Tran. 1797 part 2d.

46 And found unsuccessful.

Mr Henry then suspected that the dilatation was owing to the water which every gas contains in a larger or smaller quantity. To ascertain this, he endeavoured to deprive the carbonated hydrogen gas of as much water as possible, by making it pass over very dry potass, which attracts water with avidity. Gas treated in this manner could only be expanded one-sixth of its bulk; but on admitting a drop or two of water, the expansion went on as usual. The substance decompounded by the electricity, then, was not the carbon, but the water in the carbonated hydrogen gas. Nor is it difficult to see in what manner this decomposition is effected. Carbon at a high temperature has a greater affinity for oxygen than hydrogen has; for if the steam of water be made to pass over red hot charcoal, it is decomposed, and carbonic acid and hydrogen gas are formed. The electric explosion supplies the proper temperature; the carbon unites with the oxygen of the water, and forms carbonic acid; and the hydrogen, thus set at liberty, occasions the dilation. Carbonic acid gas is absorbed with avidity by water: and when water was admitted into 709 measures of gas thus dilated, 100 measures were absorbed; a proof that carbonic acid gas was actually present. As to the azot which Dr Austin found in his dilated gas, it evidently proceeded from the admission of some atmospheric air, about 73 parts of which in the 100 consist of this gas: for Dr Austin's gas had stood long over water; and Drs Priestley and Higgins have shewn that air in such a situation always becomes impregnated with azot. (5.)

The

(P) Ether is a very volatile and fragrant liquid, obtained by mixing spirit of wine and acids, and distilling. It shall be afterwards described.

(Q) Sulphur decomposes carbonated hydrogen gas; therefore its affinity is greater than that of carbon. The Dutch chemists melted phosphorus in carbonated hydrogen gas, but no change was produced; therefore the affinity of phosphorus is inferior to that of carbon.

(R) See next Section.—His theory was, that carbonated hydrogen gas was composed of hydrogen, and azot, and carbon of azot, and carbonated hydrogen gas, which comes nearly to the same thing with regard to the elements of carbon. It is singular enough, that though Dr Austin would not allow the presence of carbon in carbonated hydrogen gas, he actually decomposed it by melting sulphur in it: the sulphur combined with the hydrogen gas, and a quantity of carbon was precipitated. This experiment he relates without making any remarks upon it, and seems indeed not to have paid any attention to it.

(5) The decomposition of the water held in solution by the *carbonated hydrogen gas* by means of the carbon uniting to the oxygen, and forming *carbonic acid gas* while the hydrogen is set at liberty, perfectly accounts for its increased bulk. But I think it by no means accounts for the increased *consumption* of oxygen on firing it. It is true that there is an addition to the hydrogen in the reservoir; but then we must recollect all the oxygen with which it was united, is now in union with the carbon; that therefore this carbon on the *combustion* taking place will combine with just so much the less of the oxygen added, and the *additional hydrogen* will require no more oxygen to reconvert it into water than it parted with to the carbon. I cannot see then with what this extra quantity is to unite. Is it not possible Dr Austin may have been deceived in an experiment which requires so much accuracy? T. P. S.

Azot.

47 Affinities of hydrogen.

The affinities of hydrogen have not yet been afcertained, but perhaps they are as follows:

Oxygen,
Carbon,
Azot,

Sect. V. *Of Azot.*

48 Method of procuring azot.

If a quantity of iron filings and fulphur, mixed together and moiftened with water, be put into a glafs veffel full of air, it will abforb all the oxygen in the courfe of a few days; but a confiderable refiduum of air ftill remains incapable of any farther diminution. This refiduum has obtained the appellation of *azotic gas*.

49 Difcovery of azot.

It was difcovered in 1772 by Dr Rutherford, now profeffor of botany in the univerfity of Edinburgh (s). Scheele procured it by the above procefs as early as 1776, and proved that it was a diftinct fluid. Mr Lavoifier afterwards proved the fame thing, without any previous knowledge of Scheele's difcoveries.

The air of the atmofphere contains about ,73 parts of azotic gas; almoft all the reft is oxygen gas. The eafieft method of procuring azotic gas is to put fome fulphuret of potafs into a glafs veffel filled with air, and accurately clofed, and then to apply heat to the fulphuret. All the oxygen is abforbed almoft inftantly. This method was firft pointed out by Morveau.*

* *Nicholfon's Journal*, i. 268.

Mr Kirwan examined the fpecific gravity of azotic gas obtained by Scheele's procefs; it was 0,00120: it is therefore fomewhat lighter than the atmofpheric air, it is to atmofpheric air as 985 to 1000 ‖.

‖ *On Phlogifton*, § 1ft.

It tinges delicate blue colours flightly with green ‡.

50 Its properties.

It is exceedingly noxious to animals; if they are obliged to refpire it, they drop down dead almoft inftantly (T). No combuftible will burn in it. This is the reafon that a candle is extinguifhed in atmofpherical air as foon as the oxygen near it is confumed. Mr Goettling, indeed, publifhed, in 1794, that phofphorus fhone, and was converted into phofphoric acid, in pure azotic gas. Were this the cafe, it would not be true that no combuftible burns in this gas; for the converfion of phofphorus into an acid, and even its fhining, is an actual though flow combuftion. Mr Goettling's experiments were foon after repeated by Drs Scherer and Jaeger, who found, that phofphorus does not fhine in azotic gas when it is perfectly pure; and that therefore the gas on which Mr Goettling's experiments were made had contained a mixture of oxygen gas, owing principally to its having been only confined by water. Thefe refults were afterwards confirmed by Profeffor Lampadius and Profeffor Hildebrandt. It is therefore proved beyond a doubt, that phofphorus does not burn in azotic gas, and that whenever it appears to do fo, there is always fome oxygen gas prefent †.

‡ *Fourcroy, Ann. de Chim.* i. 45.

† *Nicholfon's Journal*, ii. 8.

Azotic gas is capable of diffolving phofphorus, as has been proved by the experiments of Fourcroy and Vauquelin.

It diffolves alfo a little carbon; for azotic gas obtained from animal fubftances, which contain a great deal of azot, when confined long in jars, depofits on the fides of them a black matter which has the properties of carbon ‖.

‖ *Fourcroy, Ann. de Chim.* i. 45.

Thefe two folutions the properties of which have not yet been accurately examined, are called *phofphorated and carbonated azotic gas*.

51 Production of nitric acid.

Azotic gas is capable of combuftion. Take a glafs tube, the diameter of which is about the fixth part of an inch; fhut one of its ends with a cork, through the middle of which paffes a fmall wire with a ball of metal at each end. Fill the tube with mercury, and then plunge its open end into a bafon of that fluid. Throw up into the tube as much of a mixture, compofed of 13 parts of azotic and 87 parts of oxygen gas, as will fill 3 inches. Through this gas make, by means of the wire in the cork, a number of electric explofions pafs. The volume of gas gradually diminifhes, and in its place there is found a quantity of *nitrous acid*. This acid, therefore, is compofed of azot and oxygen: and thefe two fubftances are capable of combining or, which is the fame thing, azotic gas is capable of combuftion in the temperature produced by electricity, which we know to be pretty high. The combuftibility of azotic gas, and the nature of the product, was firft difcovered by Mr Cavendifh, and communicated to the Royal Society on the 2d of June 1785 (U).

52 Attempts to decompofe azot.

The affinities of azot are ftill unknown. It has never yet been decompounded, and muft therefore, in the prefent ftate of our knowledge, be confidered as a fimple fubftance. Dr Prieftley, who obtained azotic gas at a very early period of his experiments, confidered it as a compound of oxygen gas and phlogifton, and for that reafon gave it the name of *phlogifticated air*. According to the theory of Stahl, which was then univerfally prevalent, he confidered combuftion as merely the feparation of phlogifton from the burning body. To this

---

(s) See his thefis *De Aere Mephitico*, publifhed in 1772.—"Sed aer falubris et purus refpiratione animali non modo ex parte fit mephiticus fed et *aliam indolis fuæ mutationem inde patitur*. Poftquam enim omnis aer mephiticus (carbonic acid gas) ex eo, ope lixivii cauftici fecretus et abductus fuerit, *qui tamen reftat* nullo modo falubrior inde evadit; nam quamvis nullam ex aqua calcis præcipitationem faciat haud minus quam antea *et flammam et vitam extinguit*. Page 17.

"Aer qui per carbones ignitos folle adactus fuit, atque deinde ab omni aere mephitico *(carbonic acid gas)* expurgatus, malignus tamen adhuc reperitur et omnino fimilis eft ei qui refpiratione inquinatur. Immo ab experimentis patet, hanc folam effe aeris mutationem quæ inflammationi adfcribi poteft. Si enim accenditur materies quælibet quæ ex phlogifto et bafi fixa atque fimplici conftat, *aer inde natus ne minimam aeris mephitici quantitatem in fe continere videtur*. Sic aer in quo fulphur aut phofphorus urinæ combuftus fuit, licet maxime malignus, calcem tamen ex aqua minime præcipitat. Interdum quidem fi ex phofphoro natus fuerit, nubeculam aquæ calcis inducit fed tenuiffimam, nec aeri mephitico attribuendam, fed potius acido illi quod in phofphoro ineft, et quod, ut experimenta docuerunt, hoc fingulari dote pollet." Page 19.

(T) Hence the name *azot*, given it by the French chemifts, which fignifies *deftructive to life*, from α and ζωη.

(U) It is remarkable enough, that the acidity of nitric acid was afcribed by Mayow, in 1674, to the prefence of oxygen. *Indoles cauftica fpiritus nitri* (fays he) *a particulis ejus igneo-aereis provenit*. Tract. p. 19.

Azot. this theory he made the following addition: Phlogiston is separated during combustion by means of chemical affinity: *Air* (that is, *oxygen gas*) has a strong affinity for phlogiston: Its presence is necessary during combustion, because it combines with the phlogiston as it separates from the combustible; and it even contributes by its affinity to produce that separation: The moment the air has combined with as much phlogiston as it can receive, or, to use a chemical term, the moment it is *saturated* with phlogiston, combustion necessarily stops, because no more phlogiston can leave the combustible (v): Air saturated with phlogiston is azotic gas. This was a very ingenious theory, and when Dr Priestley published it, exceedingly plausible. A great number of the most eminent chemists accordingly embraced it: But it was soon after discovered, that during combustion the quantity of air, instead of increasing, as it ought to have done, had phlogiston been added to it, actually diminished both in volume and weight. There was no proof therefore, that during combustion, any substance whatever combined with air, but rather the contrary. It was discovered also, that a quantity of air combined with the burning substance during combustion, as we have seen was the case with sulphur, phosphorus, carbon, and hydrogen; and that this air had the properties of oxygen gas. These discoveries entirely overthrew the evidence on which Dr Priestley's theory was founded: accordingly, as no attempt to decompound azot has succeeded, it has been given up by almost every chemist except Dr Priestley himself. Atmospheric air, as Scheele first proved, is composed of about 27 parts of oxygen, and 73 of azotic gas. During combustion, the oxygen is abstracted and the azotic gas remains behind.

53
Unsuccessful.

La Metherie made an attempt to prove that azot was composed of oxygen and carbon (w). He took a bit of burning charcoal, extinguished it in mercury, and then plunged it while hot into oxygen gas. On being plunged into water, one-fourth of the gas was disengaged, and part of it was found to consist of azotic gas. From this he concluded that he had formed azotic gas by combining oxygen and carbon: But it was proved by Mr Lavoisier, beyond the possibility of doubt, that oxygen and carbon form carbonic acid gas. They cannot then certainly form azot; for two contradictory facts cannot both be true. There must then have been something overlooked in the experiment. Indeed the experiment itself does not warrant the conclusion which De La Metherie drew from it. He did not ascertain whether the weight of the charcoal was diminished; and besides, there was azot mixed with the oxygen gas which he employed, as he himself has informed us: And how was it possible for him to admit the charcoal into water without, at the same time, admitting some atmospherical air?

Azot || Metals.

We have now described all the combustibles which are at present reckoned simple, except the metals. We have found, that during combustion, all of them combine with oxygen; that no part of them is disengaged, no part of them lost: we have therefore concluded, that the combustion of these substances is nothing else but the act of their uniting with oxygen. We have seen, however, that none of them, except phosphorus, was capable of uniting with oxygen at the common temperature of the atmosphere; that, in order to produce the union, heat was necessary, and that the degree of this heat was different for each. Hydrogen required a red heat, and azot a still greater (6). We have seen, too, that during these combinations a quantity of heat and light escaped. Now why is heat necessary for these combinations? and whence come the heat and the light which we perceive during the combustion of these bodies? These questions are of the highest importance, and can only be answered by a particular investigation of the nature and properties of heat and light. This investigation we shall attempt as soon as we have described the *metals* and *earths*, which form the subject of the two following chapters.

CHAP. III. *Of* METALS.

54
Properties of metals.

METALS may be considered as the great instruments of all our improvements: Without them, many of the arts and sciences could hardly have existed. So sensible were the ancients of their great importance, that they raised those persons who first discovered the art of working them to the rank of deities. In chemistry, they have always filled a conspicuous station: at one period the whole science was confined to them; and it may be said to have owed its very existence to a rage for making and transmuting metals.

55
Lustre.

1. One of the most conspicuous properties of the metals is a particular brilliancy which they possess, and which has been called the *metallic lustre*. This proceeds from their reflecting much more light than any other body; a property which seems to depend partly on the closeness of their texture. This renders them peculiarly proper for mirrors, of which they always form the basis.

56
Opacity.

2. They are absolutely opaque, or impervious to light, even after they have been reduced to very thin plates. Silver leaf, for instance, $\frac{1}{100000}$ of an inch thick, does not permit the smallest ray of light to pass through it. Gold, however, may be rendered transparent; for gold leaf, $\frac{1}{280000}$ of an inch thick, transmits light of a lively green colour*. And it is not improbable that all the other metals, as Sir Isaac Newton supposed, would become transparent, if they could be reduced to a sufficient degree of thinness. It is to this opacity that a part of the excellence of the metals, as mirrors, is owing; their brilliancy alone would not qualify them for that purpose.

* Nicholson's Notes on Fourcroy.

57
Fusibility.

3. They may be melted by the application of heat, and even then still retain their opacity. This property enables

(v) This ingenious theory was first conceived by Dr. Rutherford, as appears from the following passage of his thesis. "Ex iisdem etiam deducere licet quod aer ille malignus (azotic gas) componitur ex *aere atmosphaerico cum phlogisto unito et quasi saturato*. Atque idem confirmatur eo, quod aer qui metallorum calcinationi jam inservit, et phlogiston ab iis abripuit ejusdem plane sit indolis." *De aere Mephitico*, p. 20.

(w) Or rather of *hydrogen*, for he considered carbon itself as a compound.

(6) If this be *true*, from whence comes the nitric acid in those calcareous caves in which there is neither animal nor vegetable putrefaction, but in which nitre is formed?

Metals.

enables us to caſt them in moulds, and then to give them any ſhape we pleaſe. In this manner many elegant iron utenſils are formed.

58
Gravity.

4. Their ſpecific gravity is greater than that of any other body hitherto diſcovered.

5. They are better conductors of electricity than any other body.

59
Malleability.

6. But one of their moſt important properties is *malleability*, by which is meant the capacity of being extended and flattened when ſtruck with a hammer. This property enables us to give the metallic body any form we think proper, and thus renders it eaſy for us to convert them into the various inſtruments for which we have occaſion. All metals do not poſſeſs this property; but it is remarkable that almoſt all thoſe which were known to the ancients have it. Heat increaſes this property conſiderably.

60
Ductility.

7. Another property which is alſo wanting in many of the metals, is *ductility;* by which we mean the capacity of being drawn out into wire, by being forced through holes of various diameters. This property has by ſome been called *tenacity;* and it doubtleſs depends upon the tenacity of the various metals.

61
Calcination

8. When expoſed to the action of heat and air, moſt of the metals loſe their luſtre, and are converted into earthy-like powders of different colours and properties, according to the metal, and the degree of heat employed. Several of the metals even take fire when expoſed to a ſtrong enough heat; and after combuſtion the reſiduum is found to be the very ſame earthy-like ſubſtance. If any of theſe *calces*, as they are called, be mixed with charcoal-powder, and expoſed to a ſtrong heat in a proper veſſel, it is changed again to the metal from which it was produced. From theſe phenomena Stahl concluded that metals were compoſed of *earth* and *phlogiſton*. He was of opinion that there was only one primitive earth, which not only formed the baſis of all thoſe ſubſtances known by the name of earths, but the baſis alſo of all the metals. He found, however, that it was impoſſible to combine any mere earth with phlogiſton; and concluded, therefore, with Beccher, that there was another principle beſides earth and phlogiſton which entered into the compoſition of the metals. To this principle Beccher gave the name of *mercurial earth*, becauſe according to him, it exiſted moſt abundantly in *mercury*. This principle was ſuppoſed to be very volatile, and therefore to fly off during calcination: and ſome chemiſts even affirmed that it might be obtained in the ſoot of thoſe chimneys under which metals have been calcined.

62
Stahl's theory of the compoſition of metals

63
Defective.

A ſtriking defect was ſoon perceived in this theory. The original metal may be again produced by heating its calx along with ſome other ſubſtance which contains phlogiſton: now, if the mercurial earth flies off during combuſtion, it cannot be neceſſary for the formation of complete metals, for they may be produced without it: if, on the contrary, it adheres always to the calx, there is no proof of its exiſtence at all. Chemiſts, in conſequence of theſe obſervations, found themſelves obliged to diſcard the mercurial principle altogether, and to conclude that metals were compoſed of earth only, united to phlogiſton. But if this be really the caſe, how comes it that theſe two ſubſtances cannot be united by art? Henkel was the firſt who attempted to ſolve this difficulty. According to him, earth and phlogiſton are ſubſtances of ſo oppoſite a nature, that it is exceedingly difficult, or rather it has been hitherto impoſſible for us to commence their union; but after it has been once begun by nature, it is an eaſy matter to complete it. No calcination has hitherto deprived the metals of all their phlogiſton; ſome ſtill adheres to the calces. It is this remainder of phlogiſton which renders it ſo eaſy to reſtore them to their metallic ſtate. Were the calcination to be continued long enough to deprive them altogether of phlogiſton, they would be reduced to the ſtate of other earths; and then it would be equally difficult to convert them into metals, or, to uſe a chemical term, to *reduce* them. Accordingly we find, that the more completely a calx has been calcined, the more difficult is its reduction. This explanation was favourably received. But after the characteriſtic properties of the various *earths* had been aſcertained, and the calces of metals were accurately examined, it was perceived that the calces differed in many particulars from all the *earths*, and from one another. To call them all the ſame ſubſtance, then, was to go much farther than either experiment or obſervation would warrant, or, rather, it was to declare open war againſt both experiment and obſervation. It was concluded, therefore, that each of the metals was compoſed of a peculiar *earthy ſubſtance* combined with phlogiſton. For this great improvement in accuracy, chemiſtry is chiefly indebted to Bergman.

Metals.

64
Improved by Henkel.

65
Farther improved.

66
Still imperfect.

But there were ſeveral phenomena of calcination which had all this time been unaccountably overlooked. The calces are all conſiderably heavier than the metals from which they are obtained. Boyle had obſerved this circumſtance, and had aſcribed it to a quantity of *fire* which, according to him, became fixed in the metal during the proceſs‡. But ſucceeding chemiſts paid little attention to it, or to the action of air, till Mr Lavoiſier publiſhed his celebrated experiments on calcination, in the memoirs of the Paris Academy for 1774. He put eight ounces of *tin* into a large glaſs retort, the point of which was drawn out into a very ſlender tube to admit of eaſy fuſion. This retort was heated ſlowly till the tin began to melt, and then ſealed hermetically. This heat was applied to expel ſome of the air from the retort; without which precaution it would have expanded and burſt the veſſel. The retort, which was capable of containing 250 cubic inches, was then weighed accurately, and placed again upon the fire. The tin ſoon melted, and a pellicle formed on its top, which was gradually converted into a grey powder that ſunk by a little agitation, to the bottom of the liquid metal: in ſhort, the tin was partly converted into a *calx*. This proceſs went on for three hours; after which the calcination ſtopped, and no farther change could be produced on the metal. The retort was then taken from the fire, and found to be preciſely of the ſame weight as before the operation. It is evident, then, that no new ſubſtance had been introduced, and that therefore the increaſed weight of calces, cannot, as Boyle ſuppoſed, be owing to the fixation of fire (x).

‡ *Fire and flame weighed.*

67
Refuted by Lavoiſier.

When

(x) This experiment had been performed by Boyle with the ſame ſucceſs. He had drawn a wrong concluſion from not attending to the ſtate of the air of the veſſel. *Shaw's Boyle*, II. 394.

Metals. When the point of the retort was broken, the air rushed in with a hissing noise, and the weight of the retort was increased by ten grains. Ten grains of air, therefore, must have entered, and, consequently, precisely that quantity must have disappeared during the calcination. The metal and its calx being weighed, were found just ten grains heavier than before: therefore, the air which disappeared was absorbed by the metal: and as that part of the tin which remained in a metallic state was unchanged, it is evident that this air must have united with the calx. The increase of weight, then, which metals experience during calcination, is owing to their uniting with air (Y). But all the air in the vessel was not absorbed, and yet the calcination would not go on. It is not the whole, then, but some particular part of the air which unites with the calces of metals. By the subsequent discoveries of Priestley, Scheele, and Lavoisier himself, it was ascertained, that the residuum of the air, after calcination has been performed in it, is always pure azotic gas: It follows, therefore, that it is only the *oxygen* which combines with calces; and that a metallic calx is not a simple substance, but a compound. Mr Lavoisier observed, that the weight of the calx was always equal to that of the metal employed, together with that of the oxygen absorbed. It became a question, then, Whether metals, during calcination, lost any substance, and, consequently, whether they contained any phlogiston? Mr Lavoisier accordingly proposed this question; and he answered it himself by a number of accurate experiments and ingenious observations. Metals cannot be calcined, excepting in contact with oxygen, and in proportion as they combine with it. Consequently they not only absorb oxygen during their calcination, but that absorption is absolutely necessary to their assuming the form of a calx. If the calx of mercury be heated in a retort, to which a pneumatic apparatus is attached, to the temperature of 1200°, it is converted into pure mercury; and, at the same time, a quantity of oxygen separates from it in a gaseous form. As this process was performed in a close vessel, no new substance could enter: The calx of mercury, then, was reduced to a metallic state without phlogiston. The weights of the metal, and the oxygen gas, are together just equal to that of the calx; the calx of mercury, therefore, must be composed of mercury and oxygen; consequently, there is no reason whatever to suppose that mercury contains phlogiston. Its calcination is merely the act of uniting it with oxygen (Z). The calces of lead, silver, and gold, may be decomposed exactly in the same manner; and Mr Van Marum, by means of his great electrical machine, decomposed also those of tin, zinc, and antimony, and resolved them into their respective metals and oxygen‖. The same conclusions, therefore, must be drawn with respect to these metals. All the metallic calces may be decomposed by presenting to them substances which have a greater affinity for oxygen than they have. This is the reason that charcoal-powder is so efficacious in reducing them: and if they are mixed with it, and heated in a proper vessel, furnished with a pneumatic apparatus, it will be easy to discover what passes. During the reduction, a great deal of carbonic acid gas comes over, which, together with the metal, is equal to the weight of the calx and the charcoal: it must therefore contain all the ingredients; and we know that carbonic acid gas is composed of carbon and oxygen. During the process, then, the oxygen of the calx combined with the charcoal and the metal remained behind. It cannot be doubted, therefore, that all the metallic calces are composed of the entire metals combined with oxygen; and that calcination, like combustion, is merely the act of this combination. All metals, then, in the present state of chemistry, must be considered as simple substances; for they have never yet been decompounded.

‖ *Jour. de Phys.* 1785.

68 Oxyd and oxydation what.

The words *calx* and *calcination* are evidently improper, as they convey false ideas; we shall therefore afterwards employ, in stead of them, the words *oxyd* and *oxydation*, which were invented by the French chemists. A metallic *oxyd* signifies a metal united with oxygen; and *oxydation* implies the act of that union.

Metals are capable of uniting with oxygen in different proportions, and, consequently, of forming each of them different oxyds. These are distinguished from one another by their colour. One of the oxyds of iron, for instance, is of a green colour; it is therefore called the *green oxyd;* the other, which is brown, is called the *brown oxyd.*

69 Number of metals.

The metals at present amount to 21; only 11 of which were known before the year 1730. Their names are gold, silver, platinum, mercury, copper, iron, tin, lead, zinc, antimony, bismuth, arsenic, cobalt, nickel, manganese,

(Y) It is remarkable that John Rey, a physician of Perigord, had ascribed it to this very cause as far back as the year 1630: But his writings had excited little attention, and had sunk into oblivion, till after his opinion had been incontestibly proved by Lavoisier. Mayow also, in the year 1674, ascribed the increase of weight to the combination of metals with oxygen. *Quippe vix concipi potest* (says he), *unde augmentum illud antimonii (calcinati) nisi a particulis nitro-aereis igneisque inter calcinandum* FIXIS *procedat.* Tract. p. 28. *Plane ut antimonii fixatio non tam a sulphuris ejus externi assumptione, quam particulis nitro-aereis, quibus flamma nitri abundat,* EI INFIXIS *provenire videatur.* Ibid. p. 29.

(Z) This experiment was performed by Mr Bayen in 1774. This philosopher perceived, earlier than Lavoisier, that all metals did not contain phlogiston. "Ces experiences (says he) vont nous detromper. Je ne tiendrai plus le language des disciples de Stahl, qui seront forcés de restreindre la doctrine sur le phlogistique, ou d'avouer que les precipités mercurials, dont je parle, ne sont pas des chaux metalliques, ou enfin qu'il y a des chaux qui peuvent se reduire sans le concours du phlogistique. Les experiences que j'ai faites me force de conclure que dans la chaux mercuriale dont je parle, le mercure doit son *etat calcaire, non à la perte du phlogistique* qu'il nà pas essuyée, *mais a sa combinaison intime avec le fluide elastique,* dont le poids ajouté a celui du mercure est la seconde cause de l'augmentation de pesanteur qu'on observe dans les precipités que j'ai soumis a l'examen." *Jour. de Phys.* 1774, pages 288, 295. It was in consequence of hearing Bayen's paper read that Lavoisier was induced to turn his attention to the subject.

Gold.

manganefe, tungften, molybdenum, uranium, tellurium, titanium, chromum.

The firft eight of thefe were formerly called *metals* by way of eminence, becaufe they are poffeffed either of malleability or ductility, or of both properties together; the reft were called *femimetals*, becaufe they are brittle. But this diftinction is now pretty generally laid afide; and, as Bergman obferves, it ought to be fo altogether, as it is founded on a falfe hypothefis, and conveys very erroneous ideas to the mind. The firft four metals were formerly called *noble* or *perfect metals*, becaufe their oxyds are reducible by the mere application of heat; the next four were *imperfect metals*, becaufe their oxyds were thought not reducible without the addition of fome combuftible fubftance; but this diftinction alfo is now very properly exploded.

Sect. I. *Of Gold.*

70 Properties of gold.

Gold feems to have been known from the very beginning of the world. Its properties and its fcarcity have rendered it more valuable than any other metal.

It is of an orange red, or reddifh yellow colour, and has no perceptible tafte or fmell.

No other fubftance can be compared with it in ductility and malleability. It may be beaten out into leaves fo thin, that one grain of gold will cover $56\frac{3}{4}$ fquare inches. Thefe leaves are only $\frac{1}{282000}$ of an inch thick. But the gold leaf with which filver wire is covered has only $\frac{1}{12}$ of that thicknefs. An ounce of gold, upon filver wire, is capable of being extended more than 1300 miles in length.

Its tenacity is fuch, that a gold wire $\frac{1}{10}$ of an inch in diameter, is capable of fupporting a weight of 500 pounds without breaking‡.

‡ *Macquer's Dict.*

Its hardnefs is 6 (A); its fpecific gravity 19.3. It melts at 32° of Wedgewood's pyrometer (B). When melted, it affumes a bright bluifh green colour. It expands in the act of fufion, and confequently contracts while becoming folid more than moft metals; a circumftance which renders it lefs proper for cafting into moulds.

It requires a very violent heat to volatilize it; it is therefore, to ufe a chemical term, exceedingly *fixed*. Boyle and Kunkel kept it for fome months in a glafs-houfe furnace, and yet it underwent no change; nor did it lofe any perceptible weight, after being expofed for fome hours to the utmoft heat of Mr Parker's lens*. Mr Lavoifier, however, obferved, that a piece of filver, held over gold melted by a fire blown by oxygen gas, which produces a much greater heat than common air, was fenfibly *gilt*: Part of the metal, then, muft have been volatilized.

* *Kirwan's Miner.* i. 92.

After fufion, it is capable of affuming a cryftalline form. Tillet and Mongez obtained it in fhort quadrangular pyramidal cryftals.

71 Oxydation of gold.

It is capable of combining with oxygen, and forming an *oxyd of gold*. There are two methods of producing this combination, *the application of heat*, and *folution in acids*. When it is expofed to a very violent heat in contact with air, gold abforbs oxygen. But the temperature muft be very high; fo high, indeed, that hardly any certain method of oxydating gold by heat is known, except by electricity. When the electric explofion is tranfmitted through gold leaf placed between two plates of glafs, or when a ftrong charge is made to fall on a gilded furface—in both cafes the metal is oxydated, and affumes a purple colour. It has been faid alfo, that the fame effect has been produced by a very violent fire; but few of the inftances which have been adduced are well authenticated.

The other method of oxydating gold is much eafier. For this purpofe, equal parts of nitric and muriatic acids are mixed together (C), and poured upon gold; an effervefcence takes place, the gold is gradually diffolved, and the liquid affumes a yellow colour. It is eafy to fee in what manner this folution is produced. No metal is foluble in acids till it has been reduced to the ftate of an oxyd. There is a ftrong affinity between the oxyd of gold and muriatic acid. The nitric acid furnifhes oxygen to the gold, and the muriatic acid diffolves the oxyd as it forms (7). When nitric acid is deprived of the greater part of its oxygen, it affumes a gafeous form, and is then called *nitrous gas*. It is the emiffion of this gas which caufes the effervefcence. The oxyd of gold may be precipitated from the nitro-muriatic acid, by pouring in a little potafs diffolved in water, or, which is much better, a little lime, both of which have a ftronger affinity for muriatic acid

(A) We have borrowed from Mr Kirwan the method of denoting the different degrees of hardnefs by figures, which we think a great improvement. Thefe figures will be underftood by Mr Kirwan's own explanation, which we here fubjoin.

3, Denotes the hardnefs of chalk.
4, A fuperior hardnefs, but yet what yields to the nail.
5, What will not yield to the nail, but eafily, and without grittinefs, to the knife.
6, That which yields more difficultly to the knife.
7, That which fcarcely yields to the knife.
8, That which cannot be fcraped by a knife, but does not give fire with fteel.
9, That which gives a few feeble fparks with fteel.
10, That which gives plentiful lively fparks. *Kirwan's Mineralogy*, I. 38.

(B) According to the calculation of the Dijon academicians, it melts at 1298° Fahr.; according to Bergman, at 1301°.

(C) This mixture, from its property of diffolving gold, was formerly called *aqua regia* (for gold, among the alchymifts, was the king of metals); it is now called *nitro-muriatic acid*.

(7) I would rather, from the late experiments of the French chemifts, confider it as decompofition of the oxygenated muriatic acid which is formed on our mixing nitric and muriatic acids: part of its oxygen uniting to the gold, thus oxyding it, and the oxygenated acid paffing to the ftate of muriatic acid, which diffolves the oxyd of gold. T. P. S.

Gold. acid than the oxyd has. This oxyd is of a yellow colour.

It is probable that gold is capable of two different degrees of oxydation, and of forming two different oxyds, *the yellow* and *the purple*: But neither the quantity of oxygen contained in these oxyds, nor the differences between them, have been accurately ascertained. The oxyds of gold may be decompofed in close veffels by the application of heat. The gold remains fixed, and the oxygen affumes the gafeous form. They may be decompofed, too, by all the fubftances which have a ftronger affinity with oxygen than gold has. The affinities of the oxyds of gold, according to Bergman†, are as follows:

† *Bergman on Elective Attractions, Opufc.* t. 3.

Muriatic acid,
Nitro muriatic,
Nitric,
Sulphuric,
Arfenic,
Fluoric,
Tartarous,
Phofphoric,
Sebacic,
Pruffic,
Fixed alkali (D),
Ammonia,

Gold is not changed either by air or water. It does not feem capable of combining either with fulphur or carbon. Mr Pelletier combined it with phofphorus, by melting together in a crucible half an ounce of gold and an ounce of phofphoric glafs (E), furrounded with charcoal. The *phofphuret of gold* thus produced was brittle, whiter than gold, and had a cryftallized appearance. It was compofed of 23 parts of gold and one of phofphorus †. He formed the fame compound by dropping fmall pieces of phofphorus into gold in fufion ‡.

72 Phofphuret of gold.

† *Ann. de Chim.* i. 71.
‡ *Ibid.* xiii. 104.

Gold is alfo capable of combining with moft of the metals. Its affinities are placed, by Bergman, in the following order:

Mercury,
Copper,
Silver,
Lead,
Bifmuth,
Tin,
Antimony,
Iron,
Platinum,
Zinc,
Nickel,
Arfenic,
Cobalt,
Manganefe,
Phofphorus?
Sulphurets of alkalies.

Sect. II. *Of Silver.*

Silver.

73 Properties of filver.

Silver appears to have been known almoft as early as gold. It is a metal of a fhining white colour, without either tafte or fmell.

It is the moft malleable and ductile of all metals except gold, and perhaps platinum. It can be reduced to leaves about $\frac{1}{160000}$ of an inch thick, and drawn into wire much finer than a human hair.

Its tenacity is fuch, that a wire of filver, $\frac{1}{10}$ of an inch in diameter, is capable of fuftaining 270 pounds without breaking ||. || *Macquer's Dict.*

Its hardnefs is 6,5.* Its fpecific gravity, before hammering, is 10,474; after hammering, 10,510 ‡: for it is remarkable that the fpecific gravity of almoft all the metals is increafed by hammering.

* *Kirwan.*
‡ *Briffon.*

It continues melted at 28° Wedgewood (F), but requires a greater heat to bring it to fufion †. † *Kirwan's Mineral.* ii. 107.

The experiments of the French academicians have proved that it may be volatilized, but that it requires a very violent heat.

When cooled flowly, it affumes a cryftalline form. Tillet and Mongez obtained it in quadrangular pyramidal cryftals, both infulated and in groups.

74 Oxyds of filver.

Silver may be combined with oxygen, and converted into an oxyd by expofure to a very violent heat. By this method Junker partly converted it into a *glafs*; and Macquer, by expofing it 20 times fucceffively to the heat of a porcelain furnace, obtained a *glafs* (G) of an olive green colour ‡. The oxyd of filver may alfo be formed by diffolving the metal in an acid, and precipitating it from its folution by potafs, lime, &c: for, during its folution, the metal becomes oxydated. Little is known at prefent concerning the oxyds of filver, nor whether there be more than two, the *black* and the *blue*. From the experiments of Wenzel and Bergman, it follows, that one oxyd of filver is compofed of about 90 parts of metal and 10 of oxygen ||. The affinities of the oxyds, according to Bergman, are as follows:

‡ *Macquer's Dict.*
|| *Kirwan's Miner.* ii. 493.

Muriatic acid,
Sebacic,
Oxalic,
Sulphuric,
Saccholactic,
Phofphoric,
Sulphurous,
Nitric,
Arfenic,
Fluoric,
Tartaric,
Citric,
Formic,
Lactic,
Acetous,
Succinic,
Pruffic,

Carbonic,

(D) Have the alkalis any affinity for the yellow oxyd? Is not their affinity confined to the purple oxyd alone? And does not this oxyd act as an acid?

(E) Phofphoric acid evaporated to drynefs and then fufed.

(F) According to the Dijon academicians, it melts at 1044° Fahr.; according to Bergman, at 1000°.

(G) Metallic oxyds, after fufion, are called *glafs*, becaufe they acquire a good deal of refemblance, in fome particulars, to common glafs.

Silver.

Carbonic,
Ammonia.

75 Sulphuret of silver.

When silver is melted with sulphur in a low red heat, it combines with it and forms *sulphuret of silver*. It is very difficult to determine the proportion of the ingredients which enter into the composition of this substance, because there is an affinity between silver and its sulphuret, which disposes them to combine together. The greatest quantity of sulphur which a given quantity of silver is capable of taking up is, according to Wenzel, $\frac{15}{100}$.* Sulphuret of silver is of a black or very deep violet colour, brittle and much more fusible than silver. If sufficient heat be applied, the sulphur is volatilized, and the metal remains behind in a state of purity.

* Ibid. 492.

76 Phosphuret of silver.

If one ounce of silver, one ounce of phosphoric glass, and two drams of charcoal, be mixed together, and heated in a crucible, *phosphuret of silver* is formed. It is of a white colour, and appears granulated, or as it were crystallized. It breaks under the hammer, but may be cut with a knife. It is composed of four parts of silver and one of phosphorus. Heat decomposes it by separating the phosphorus †. Pelletier has observed, that silver in fusion is capable of combining with more phosphorus than solid silver: for when phosphuret of silver is formed by projecting phosphorus into melted silver, after the crucible is taken from the fire a quantity of phosphorus is emitted the moment the metal congeals ‡.

† Pelletier, Ann. de Chim. i. 73.

‡ Ibid. xiii. 110.

Silver does not seem capable of combining with carbon.

77 Alloys of silver.

Silver is capable of combining with gold, and forming an *alloy* (H) composed of one part of silver and five of gold. That this is the proportion of the ingredients, was discovered by Homberg. He kept equal parts of gold and silver in gentle fusion for a quarter of an hour, and found, on breaking the crucible, two masses, the uppermost of which was pure silver, the undermost the whole gold combined with $\frac{1}{5}$ of silver. Silver, however, may be mixed with gold in almost any proportion. But there is a great difference between the mixture of two substances and their chemical combination. Metals which melt nearly at the same temperature, may be mixed from that very circumstance in any proportion; but substances can combine chemically only in one proportion. This observation, which is certainly of importance, was first made, as far as we know, by Mr Keir ‖. The alloy of silver and gold is of a greenish colour, but its properties have not yet been accurately examined.

Silver ‖ Platinum.

‖ Translation of Macquer's Dict. art. Allay.

78 Becomes tarnished by exposure.

Silver is not affected by water, nor by exposure to the air; but Mr Proust has remarked, that when long exposed in places frequented by men, as in churches, theatres, &c. it acquires a covering of a violet colour, which deprives it of its lustre and malleability. This covering, which forms a thin layer, can only be detached from the silver by bending it, or breaking it in pieces with a hammer. It was examined by Mr Proust, and found to be *sulphuret of silver*. He accounts for this transition of the silver into a *sulphuret*, by supposing that a quantity of sulphur is constantly formed and exhaled by living bodies.*

* Ann. de Chim. i. 142.

79 Its affinities.

The affinities of silver, according to Bergman, are as follows:

Lead,
Copper,
Mercury,
Bismuth,
Tin,
Gold,
Antimony,
Iron,
Manganese,
Zinc,
Arsenic,
Nickel,
Platinum,
Sulphurets of alkalies,
Sulphur,
Phosphorus.

Sect. III. *Of Platinum.*

The metals hitherto described have been known to mankind from the earliest ages, and have been always in high estimation on account of their beauty, scarcity, ductility, and indestructibility. But platinum, though perhaps inferior to them in none of these qualities, and certainly far superior in others, was unknown, as a distinct metal, before the year 1752 (I).

80 Discovery of platinum.

It has been found only in America, in Choco in Peru,

(H) Metals combined together are called *alloys* or *allays*.

(I) Father Cortinovis, indeed, has attempted to prove, that this metal was the *electrum* of the ancients. See the *Chemical Annals of Brugnatelli*, 1790. That the electrum of the ancients was a metal, and a very valuable one, is evident from many of the ancient writers, particularly Homer. The following lines of Claudian are alone sufficient to prove it:

Atria cinxit ebur, trabibus solidatur ahenis
Culmen et in celsas surgunt electra *columnas*. L. I. v. 164.

Pliny gives us an account of it in his Natural History. He informs us that it was a composition of silver and gold; and that by candle-light it shone with more splendor than silver. The ancients made cups, statues, and columns of it. Now, had it been our platinum, is it not rather extraordinary that no traces of a metal, which must have been pretty abundant, should be perceptible in any part of the old continent?

As the passage of Pliny contains the fullest account of electrum to be found in any ancient author, we shall give it in his own words, that every one may have it in his power to judge whether or not the description will apply to the platinum of the moderns.

" Omni auro inest argentum vario pondere.—Ubicunque quinta argenti portio est, *electrum* vocatur. Scrobes eæ reperiuntur in Canaliensi. Fit et cura electrum argento addito. Quod si quintam portionem excessit, incudibus

Platinum. Peru, and in the mine of Santa Fe, near Carthagena. The workmen of theſe mines muſt no doubt have been early acquainted with it; but they ſeem to have paid very little attention to it. It was unknown in Europe till Mr Wood brought ſome of it from Jamaica in 1741. Soon after it was noticed by Don Antonio de Ulloa, a Spaniſh mathematician, who had accompanied the French academicians to Peru in their voyage to meaſure a degree of the meridian. In the year 1752, it was examined by Scheffer of Sweden, and diſcovered by him to be a new metal, approaching very much to the nature of gold, and therefore called by him *aurum album, white gold.* Soon after it was examined by Lewis, Margraf, Macquer and Beaumé, Morveau, Bergman, and many other illuſtrious chemiſts.

81 Its properties.

Platinum, when pure, is of a white colour like ſilver, but not ſo bright (κ). It has no taſte nor ſmell.

It is both ductile and malleable; but the preciſe degree has not yet been aſcertained. It has been drawn into a wire of $\frac{1}{1940}$ of an inch in diameter. This wire admitted of being flattened, and had more ſtrength than a wire of ſilver or gold of the ſame ſize‡.

‡ *Withering.*

It is exceedingly difficult to fuſe it. Macquer and Beaumé ſucceeded by means of a powerful burning-glaſs. It melts more eaſily when mixed with other ſubſtances. Its fixity is ſtill greater than its infuſibility. If the ſtrongeſt fires cannot melt it, much leſs can they volatilize it.

Its hardneſs is 7,5‖. Its ſpecific gravity, after being hammered, is 23,000; ſo that it is by far the heavieſt body known.

‖ *Kirwan's Miner.* ii. 103.

Some of the experiments which have been made on platinum ſeem to prove that it may be oxydated by the application of a violent heat. The oxyd of this metal may be eaſily formed by diſſolving platinum in nitro-muriatic acid, and precipitating it by means of an earth or potaſs. The various oxyds of platinum have never yet been examined with accuracy. The one at preſent beſt known poſſeſſes, as Mr Berthollet has proved, the properties of an acid.

82 Phoſphuret of platinum.

The *ſulphuret of platinum* is unknown.

By mixing together an ounce of platinum, an ounce of phoſphoric glaſs, and a dram of powdered charcoal, and applying a heat of about 32° Wedgewood, Mr Pelletier formed a *phoſphuret of platinum* weighing more than an ounce. It was partly in the form of a button, and partly in cubic cryſtals. It was covered above by a blackiſh glaſs. It was of a ſilver white colour, very brittle, and hard enough to ſtrike fire with ſteel. When expoſed to a fire ſtrong enough to melt it, the phoſphorus was diſengaged, and burnt on the ſurface†.

† *Ann. de Chim.* i. 71.

He found alſo, that when phoſphorus was projected on red hot platinum, the metal inſtantly fuſed, and formed a phoſphuret. As heat expels the phoſphorus, Mr Pelletier has propoſed this as an eaſy method of purifying platinum*.

* *Ibid.* xiii. 105.

Platinum does not ſeem capable of combining with carbon.

Platinum ‖ Mercury.

It is not in the leaſt affected by the action of water or air.

83 Alloys of platinum.

1. When gold and Platinum are expoſed to a ſtrong heat, they combine, and form an alloy of a much whiter colour, but nearly as ductile as gold. The proportions of the ingredients are not known. When $\frac{1}{47}$ only of the alloy is platinum, the gold is ſcarcely altered in colour.

2. Whether ſilver and platinum combine chemically has not yet been properly aſcertained. When fuſed together (for which a very ſtrong heat is neceſſary), they form a mixture not ſo ductile as ſilver, but harder and leſs white. The two metals are ſeparated by keeping them for ſome time in the ſtate of fuſion; the platinum ſinking to the bottom from its weight. This circumſtance would induce one to ſuppoſe that there is very little affinity between them.

Sect. IV. *Of Mercury.*

Mercury, called alſo *quickſilver*, was known to the ancients, and ſeems to have been employed by them in gilding.

84 Properties of mercury.

It is of a white colour, exactly like that of poliſhed ſilver. It has no taſte, but acquires a ſlight odour when rubbed between the hands.

Its ſpecific gravity is 13,568†.

† *Briſſon.*

It differs from all other metals in always exiſting, at the common temperature of the atmoſphere, in a ſtate of fluidity. It freezes at 39°*; or, which is the ſame thing, it ceaſes to be a ſolid, and melts whenever it is placed in a temperature above 39°. It boils at the temperature of 600°.

* See *Macnab's Experiments Phil. Tranſ.*

From the experiments made on frozen mercury in Ruſſia, Hudſon's Bay, and Britain, we know that this metal, when ſolid, is malleable; but the extreme difficulty of examining it in that ſtate on account of the lowneſs of the temperature, has rendered it hitherto impoſſible to aſcertain the preciſe degree either of its malleability, ductility, or hardneſs.

85 It forms three oxyds:

Mercury is capable of combining with oxygen, and of forming *oxyds*, differing from each other in the quantity of oxygen which they contain. The oxyds of mercury, at preſent known, are the *black*, the *yellow*, and the *red*.

86 The black oxyd,

1. When mercury is agitated for ſome time in contact with oxygen gas, or atmoſpheric air, it is partly converted into a greyiſh-black powder, and at the ſame time part of the oxygen diſappears. This is the *black* oxyd of mercury. It is not known how much oxygen it contains, nor even whether the whole of the mercury which compoſes it be actually combined with oxygen.

87 Yellow oxyd,

2. The beſt way of forming the yellow oxyd is to diſſolve mercury, either in boiling ſulphuric acid or in cold nitric acid. During its ſolution, it deprives theſe acids of juſt as much oxygen as is neceſſary to convert it

bus non reſtitit. Et electro auctoritas, Homero teſte, qui Menelai regiam auro, electro, argento, ebore fulgere tradit. Minervæ templum habet Lindos inſulæ Rhodiorum in quo Helena ſacravit calicem ex electro.—Electri natura eſt ad lucernarum lumina clarius argento ſplendere. Quod eſt nativum, et venena deprehendit. Namque diſcurrunt in calicibus arcus cœleſtibus ſimiles cum igneo ſtridore, et gemina ratione prædicunt."—*Lib.* xxxiii. *cap.* iv.

(κ) To this colour it owes its name. *Plata*, in Spaniſh, is *ſilver*; and *platina*, *little ſilver*, was the name firſt given to the metal. Bergman changed that name into *platinum*, that the Latin names of all the metals might have the ſame termination and gender. It was, however, firſt called *platinum* by Linnæus.

Mercury.

it into a yellow oxyd; and if potass or lime be afterwards added to the solution, it precipitates, and may be obtained pure by washing it with water. It is a bright yellow coloured powder, which acts very powerfully as an emetic. From the observations of Bergman, it appears that it is composed of about 96,8 parts of mercury, and 3,2 of oxygen*.

* Kirwan's Miner. ii. 489.

88 And red oxyd.

3. The *red oxyd* of mercury may be prepared, either by distilling nitric acid off the metal repeatedly, or by keeping mercury for a long time exposed to a heat sufficient to evaporate it while it is in contact with air. When formed by the first process it was formerly called *red precipitate*; when by the last, *precipitate per se*. It is a beautiful red powder, or rather small red crystals, which have some escharotic qualities. When prepared by the second process, the heat must not be much below 600°, nor much above 800°, otherwise no union would take place; and it must be continued for some weeks. From the experiments of Mr Kirwan, it appears to contain 92,6 parts of mercury, and 7,4 of oxygen*.

† Kirwan's Miner. ii. 489.

These oxyds may be decomposed by the application of a heat amounting to 1200°. The oxygen flies off in the form of gas, and running mercury remains behind.

89 Their affinities.

The affinities of the oxyds of mercury, according to Bergman, are as follows:

Sebacic acid,
Muriatic,
Oxalic,
Succinic,
Arsenic,
Phosphoric,
Sulphuric,
Benzoic(L)?
Saccholactic,
Tartarous,
Citric,
Sulphurous,
Nitric,
Fluoric,
Zoonic(M)?
Acetous,
Boracic,
Prussic,
Carbonic.

90 Black sulphuret of mercury.

When two parts of mercury and three parts of flowers of sulphur are triturated for some time together, or when equal parts of mercury and melted sulphur are mixed together, they combine, and form a black powder, formerly called *ethiops mineral*, and now *black sulphuret of mercury*.

91 Red sulphuret.

When 300 grains of mercury, and 68 of sulphur, with a few drops of solution of potass to moisten them, are triturated for some time in a porcelain cup, by means of a glass pestle, black oxyd of mercury is produced. Add to this 160 grains of potass, dissolved in as much water. Heat the vessel containing the ingredients over the flame of a candle, and continue the trituration without interruption during the heating. In proportion as the liquid evaporates, add clear water from time to time, so that the oxyd may be constantly covered to the depth of near an inch. The trituration must be continued about two hours; at the end of which time the mixture begins to change from its original black colour to a brown, which usually happens when a large part of the fluid is evaporated. It then passes very rapidly to a red. No more water is to be added; but the trituration is to be continued without interruption. When the mass has acquired the consistence of a jelly, the red colour becomes more and more bright, with an incredible degree of quickness. The instant the colour has acquired its utmost beauty, the heat must be withdrawn, otherwise the red passes to a dirty brown. This red powder is the red sulphuret of mercury, called formerly *cinnabar*, and, when reduced to a fine powder, *vermilion*(N). The process above described, has been lately discovered by Mr Kirchoff, and is by far the simplest and cheapest mode of forming red sulphuret with which we are acquainted*. Count De Moussin Pouschin has discovered, that its passing to a brown colour may be prevented by taking it from the fire as soon as it has acquired a red colour, and placing it for two or three days in a gentle heat, taking care to add a few drops of water, and to agitate the mixture from time to time. During this exposure, the red colour gradually improves, and at last becomes excellent. He discovered also, that when this sulphuret is exposed to a strong heat, it becomes instantly brown, and then passes into a dark violet; when taken from the fire, it passes instantly to a beautiful carmine red†.

* Nicholson's Journ. ii. 1.

† Ibid. p. 7.

The difference between these two sulphurets has never yet been ascertained. One would be apt to suspect at first that the black sulphuret consists of the real sulphuret of mercury combined with sulphur; the red, of the sulphuret of mercury combined with mercury, and that the real sulphuret of mercury was not yet accurately known. But it cannot be doubted that, during the formation of the *red sulphuret*, according to Kirchoff's process, there is an absorption of oxygen. The phenomena above described point out *that* almost incontestibly; and we observed, on attempting to repeat the experiment, that the black sulphuret, during its trituration, emitted sulphurated hydrogen gas. Perhaps, then, the mercury may be oxydated. We suspected at first that part of the sulphur might be converted into an acid; but on attempting an alteration of the process in consequence of that supposition, we could not succeed.

The red sulphuret of mercury is found naturally in several parts of the world. It used to be prepared by forming a black sulphuret with three parts of sulphur and one of mercury, and then setting fire to it. Part of the sulphur is burnt, and there remains behind a violet coloured body, which is powdered and put into a glass vessel, to the bottom of which a red heat is applied. A reddish

(L) Benzoat of mercury is decomposed by sulphuric acid. *Trommsdorf Ann. de Chim.* xi. 316.

(M) Zoonic acid decomposes the acetite of mercury. *Berthollet.*

(N) The word *vermilion*, is derived from the French word *vermeil*, which comes from *vermiculus* or *vermiculum*, names given in the middle ages to the *kermes*, or *cocus ilicis*, well known as a red dye. *Vermilion* originally signified the red dye of the kermes. See *Beckmann's Hist. of Discoveries*, II. 180.

Mercury.

A reddiſh brown ſubſtance ſublimes, which is red *ſulphuret of mercury*; but its colour is not nearly equal to that which is prepared by Kerchoff's proceſs.

92 Phoſphuret of mercury.

Mr Pelletier, after ſeveral unſucceſsful attempts to form phoſphuret of mercury, at laſt ſucceeded by diſtilling a mixture of red oxyd of mercury and phoſphorus. Part of the phoſphorus combined with the oxygen of the oxyd, and was converted into an acid; the reſt combined with the mercury.

Phoſphuret of mercury is of a black colour, of a pretty ſolid conſiſtence, and capable of being cut with a knife. When expoſed to the air, it exhaled vapours of phoſphorus||.

|| *Ann. de Chim.* xiii. 122.

Mercury does not ſeem capable of combining with carbon.

93 Its amalgams.

The combinations of mercury with the other metals are called *amalgams*.

1. The amalgam of gold forms very readily, becauſe there is a very ſtrong affinity between the two metals. If a bit of gold be dipped into mercury, its ſurface, by combining with mercury, becomes as white as ſilver. The eaſieſt way of forming this amalgam is to throw ſmall pieces of red hot gold into mercury. The proportions of the ingredients are not eaſily determined, becauſe the amalgam has an affinity both for the gold and the mercury; in conſequence of which they appear to combine in any proportion. Moſt probably it is compoſed of two parts of gold and one of mercury. The combination is formed moſt readily in theſe proportions; and if too much mercury be added, it may be ſeparated by filtration. The amalgam is of a white colour, and of the conſiſtence of butter†. This amalgam cryſtallizes in quadrangular priſms; which cryſtals, according to the Dijon academicians, are compoſed of ſix parts of mercury and one of gold. It is much uſed in gilding.

† *Keir's Notes on Macquer's Dict.* art. *Amalgam.*

2. The amalgam of ſilver is made in the ſame manner. It forms dendritical cryſtals, which, according to the Dijon academicians, contain eight parts of mercury and one of ſilver. Gellert was the firſt who remarked that its ſpecific gravity was greater than that of mercury, though that of ſilver be leſs.

3. Dr Lewis attempted to form an amalgam of platinum, but hardly ſucceeded, after a labour which laſted for ſeveral weeks. Mr Morveau ſucceeded by means of heat†. But a much more expeditious method has been lately diſcovered by Count Mouſſin Pouſchin. He took a dram of the orange-coloured ſalt, compoſed of *oxyd of platinum and ammonia* (O), and triturated it with an equal weight of mercury in a mortar of chalcedony. In a few minutes the ſalt became brown, and afterwards acquired a greeniſh ſhade. The matter was reduced to a very fine powder. Another dram of mercury was added, and the trituration continued: The matter became grey. A third dram of mercury began to form an amalgam; and ſix drams made the amalgam perfect. The whole operation ſcarce laſted 20 minutes. Mercury was added till it amounted to nine times the weight of the ſalt, and yet the amalgam continued very tenacious. It was eaſily ſpread out under the peſtle; it received the impreſſion of the moſt delicate ſeals, and had a very cloſe and brilliant grain. This amalgam is decompoſed, and the mercury paſſes to the ſtate of black oxyd by the ſimple contact of ſeveral of the metals and a great number of animal matters. This effect even takes place on rubbing it between the fingers*.

† *Ann. de Chim.* xxiv. 205.

Copper.

* *Ibid.*

94 Affinities.

The affinities of mercury, as aſcertained by the experiments of Morveau (P), are as follows:

Gold,
Silver,
Tin,
Lead,
Biſmuth,
Zinc,
Copper,
Antimony,
Arſenic (Q),
Iron.

Sect. V. *Of Copper.*

Except gold and ſilver, copper ſeems to have been more early known than any other metal. In the firſt ages of the world, before the method of working iron was diſcovered, copper was a principal ingredient in all domeſtic utenſils and inſtruments of war. Even during the Trojan war, as we learn from Homer, the combatants had no other armour but what was made of bronze, which is a mixture of *copper and tin*. The word *copper* is derived from the iſland of Cyprus, where it was firſt diſcovered, or at leaſt wrought to any extent, by the Greeks.

95 Properties of copper.

Copper is of a pale red colour with a ſhade of yellow. Its taſte is ſtyptic and nauſeous; and when rubbed it emits a diſagreeable ſmell. It poſſeſſes a conſiderable degree of malleability, though leſs than ſilver. Its tenacity is ſuch, that a wire of $\frac{1}{10}$ of an inch in diameter can ſuſtain a weight of $299\frac{1}{4}$ pounds without breaking†.

† *Macquer's Dict.*

Its hardneſs is 8 ‡. Its ſpecific gravity, when not hammered, is 7,788; when wire-drawn, 8,878||. The ſpecific gravity of Japan copper is 9,000*; that of Swediſh copper, 9,3243†.

‡ *Kirwan's Miner.* ii. 127.

|| *Briſſon.*

It melts at 27° Wedgewood; according to the calculation of the Dijon academicians, at 1449° Fahrenheit. When allowed to cool ſlowly, it aſſumes a cryſtalline form. The Abbé Mongez, to whom we owe many valuable experiments on the cryſtallization of metals, informs us, that theſe cryſtals are quadrangular pyramids, frequently inſerted into one another.

* *Keir's Notes on Macquer's Dict.*

† *Bergman,* ii. 263.

96 Brown oxyd of copper.

When copper is heated red hot in contact with air, it is ſoon covered with a brown earthy cruſt, which may be eaſily ſeparated by hammering or by plunging the metal into water. If the heat be continued, another ſcale of the ſame kind ſoon forms; and by continuing the proceſs the whole metal may be converted into an earthy-like cruſt, which is merely a combination of copper and oxygen, and is therefore called *brown oxyd of copper*. It is compoſed of about 84 parts of copper and 16 of oxygen‡.

‡ *Kirwan's Miner.* ii. 487.

97 Blue and green oxyds.

When copper is diſſolved in ſulphuric acid, and precipitated by means of lime, it falls in the form of a blue-coloured powder, which is the *blue oxyd of copper*. If this

(O) Ammonia is an alkali hereafter to be deſcribed. It is often called, in Engliſh, *hartſhorn*.

(P) We ſhall have occaſion to conſider theſe celebrated experiments afterwards.

(Q) Theſe two are added from Bergman. Bergman places *lead* before tin, and zinc before biſmuth.

Copper. this oxyd of copper be dried in the open air, it aſſumes a green colour, and is then called the *green oxyd of copper*. This laſt oxyd may alſo be produced by diſtilling a ſufficient quantity of nitric acid off copper. Little ſatisfactory is yet known with reſpect to theſe oxyds; it has not even been aſcertained whether the blue and green be really two different oxyds, or whether the difference in colour be owing to ſome other cauſe. It is probable, however, that the *green* oxyd contains more oxygen than the blue; becauſe the blue oxyd aſſumes a green colour when expoſed for ſome time to the open air, during which it may be ſuppoſed to abſorb oxygen. An experiment of Fourcroy proves inconteſtibly, that the *brown* oxyd contains leſs oxygen than the green. He converted the green oxyd into the brown by applying heat; and during the diſtillation obtained oxygen gas‖.

‖ *Fourcroy*, iii. 101.

98 Their affinities.

The affinities of the oxyds of copper, according to Bergman, are as follows:

Pyromucous acid*,
Oxalic,
Tartarous,
Muriatic,
Sulphuric,
Saccholactic,
Nitric,
Sebacic,
Arſenic,
Phoſphoric,
Succinic,
Fluoric,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Pruſſic,
Carbonic,
Fixed alkalies,
Ammonia,
Fixed oils.

* *Schrickel.*

When copper is long expoſed to the air, its ſurface becomes covered over with a green cruſt, which is *green oxyd of copper*. This oxydation never penetrates beyond the ſurface.

Copper is not attacked by water at the boiling temperature; but if cold water be allowed to remain long on its ſurface, the metal becomes partly oxydated.

99 Sulphuret of copper.

Sulphur mixes readily with copper. The combination may be formed by mixing the ingredients together and applying a pretty ſtrong heat. *Sulphuret of copper* is brittle, ſofter than copper, of a black colour externally, and within of a leaden grey. It is compoſed, according to Kirwan's experiments, of 81 parts of copper and 19 of ſulphur*.

* *Kirwan's Miner.* ii. 508.

100 Phoſphuret of copper.

Mr Pelletier formed *phoſphuret of copper* by melting together one ounce of copper, one ounce of phoſphoric glaſs, and one dram of charcoal. It was of a white colour. On expoſure to the air, it loſt its luſtre and became blackiſh‡. Margraf was the firſt perſon that formed this phoſphuret. His method was to diſtil phoſphorus and brown oxyd of copper together. It is formed moſt eaſily by projecting phoſphorus into red hot copper. According to Pelletier, it contains 20 parts of phoſphorus and 80 of copper*. This phoſphuret is harder than iron: It is not ductile, and yet cannot eaſily be pulveriſed. Its ſpecific gravity is 7,1220. It cryſtallizes in tetrahedral priſms‡.

‡ *Ann. de Chim.* i. 74.

* *Ibid.* xiii. 3.

‡ *Sage, Journ. de Phyſ.* xxxviii. 468.

Copper ‖ Iron.

101 Alloys of copper.

1. Copper combines readily with gold when the two metals are melted together. The compound is of a reddiſh colour, more fuſible than gold, but leſs ductile. The proportions of the ingredients which form this alloy are not known; nor would it be eaſy to aſcertain them, as the two metals are almoſt equally fuſible. The current gold of this country is compoſed of 11 parts of gold and one part of copper.

2. The alloy of copper and ſilver is made as eaſily as that of gold, and the properties are equally unknown. It is harder and more ſonorous than ſilver. The current ſilver coin of Britain is compoſed of 15 parts of ſilver and one of copper.

3. Platinum combines readily with copper. The alloy is much more fuſible than platinum; it is ductile, hard, takes a fine poliſh, and is not liable to tarniſh. This alloy has been employed with advantage for compoſing the mirrors of reflecting teleſcopes.

4. The amalgam of copper cannot be formed by ſimply mixing that metal with mercury, nor even by the application of heat; becauſe the heat neceſſary to melt copper ſublimes mercury. Dr Lewis has given us ſeveral proceſſes for forming this amalgam. One of the ſimpleſt is to triturate mercury with a quantity of common ſalt and verdigriſe; a ſubſtance compoſed of oxyd of copper and vinegar. The theory of this proceſs is not very obvious.

102 Its affinities.

The affinities of copper are, according to Bergman, as follows:

Gold,
Silver,
Arſenic,
Iron,
Manganeſe,
Zinc,
Antimony,
Platinum,
Tin,
Lead,
Nickel,
Biſmuth,
Cobalt,
Mercury,
Sulphuret of alkali,
Sulphur,
Phoſphorus.

Sect. VI. *Of Iron.*

103 Diſcovery of iron.

Iron, the moſt abundant and moſt uſeful of all the metals, was neither known ſo early, nor wrought ſo eaſily, as gold, ſilver, and copper. For its diſcovery we muſt have recourſe to the nations of the eaſt, among whom, indeed, almoſt all the arts and ſciences firſt ſprung up. The writings of Moſes (who was born about 1635 years before Chriſt) furniſh us with the ampleſt proof at how early a period it was known in Egypt and Phœnicia. He mentions furnaces for working iron‡, ores from which it was extracted*; and tells us, that ſwords‖, knives¶, axes†, and tools for cutting ſtones§, were then made of that metal. How many ages before the birth of Moſes iron muſt have been diſcovered in theſe countries, we may perhaps conceive, if we reflect, that the knowledge of iron was brought

‡ Deut. iv. 20.

¶ Levit. i. 17.
† Deut. xviii. 5.
§ *Ibid.* xxvii. 5.

Iron.

brought over from Phrygia to Greece by the Dactyli*, who settled in Crete during the reign of Minos I. about 1431 years before Christ; yet during the Trojan war, which happened 200 years after that period, iron was in such high estimation, that Achilles proposed a ball of it as one of his prizes during the games which he celebrated in honour of Patroclus (R). At that period none of their weapons were formed of iron. Now if the Greeks in 200 years had made so little progress in an art which they learned from others, how long must it have taken the Egyptians, Phrygians, Chalybes, or whatever nation first discovered the art of working iron, to have made that progress in it which we find they had done in the days of Moses?

* *Hesiod*, as quoted by *Pliny*, lib. vii. c. 57.

104 Its properties.

Iron, when fresh broken, is of a bluish grey colour. It has a styptic taste, and emits a smell when rubbed.

It is malleable and ductile in every temperature; and its malleability is increased in proportion as the temperature augments. Its tenacity is such, that an iron wire $\frac{1}{10}$ of an inch in diameter sustains a weight of 450 pounds without breaking.*

* *Macquer's Dict.*

Its hardness is such, that it may be easily reduced to powder by the application of a file. Its specific gravity is 7,788. It is infusible in the strongest heats hitherto produced.

It is attracted by the magnet or loadstone, and is itself capable of becoming magnetic; but it retains this property only for a very short time.

It is not hardened by being plunged into liquids while hot, nor softened by being cooled slowly.

Iron combines with oxygen very readily. When kindled in oxygen gas, it burns with great rapidity and splendor, and is in this manner converted into an oxyd. It is converted into an oxyd also when surrounded by moist air, or when plunged in water; because it has a stronger affinity for oxygen than hydrogen has, and is therefore capable of decomposing water.

105 Forms two oxyds.

Mr Proust has lately proved, that there are only two oxyds of iron, the *green*, and the *brown* or *red*, and that all the other supposed oxyds are merely mixtures of these two in various proportions†.

† *Ann. de Chim.* xxiii. 85. and *Nicholson's Journal*, i. 453.

The *green oxyd* may be obtained by dissolving iron in sulphuric acid, and then precipitating it by potass. It is a light, green-coloured, earthy-like substance, composed, as Mr Lavoisier has shewn, of 27 parts of oxygen, and 73 of iron‡. When this oxyd is exposed to the air, it quickly absorbs more oxygen, and is converted into a brown powder, which is the *brown oxyd*. Mr Proust has proved that it contains 52 parts of iron and 48 of oxygen. This oxyd is well known under the name of *rust of iron*, which is generally, however, or perhaps always, combined with carbonic acid gas.

‡ *Mem. Acad. Par.* 1782.

106 Their affinities.

The affinities of these oxyds, according to Bergman, are as follows:

Gallic acid?
Oxalic acid,
Tartarous,
Camphoric,*
Sulphuric,
Saccholactic,
Muriatic,
Pyromucous‡,
Nitric,
Sebacic,
Phosphoric,
Arsenic,
Fluoric,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Prussic,
Carbonic.

* *La Grange.*

‡ *Schrickel.*

107 Sulphuret,

Iron unites readily with sulphur. Sulphuret of iron, formerly called *pyrites*, is found ready formed in many parts of the world. It is not easy to determine the proportions of its ingredients, because it is capable of combining both with iron and sulphur, and consequently, if there happens to be any excess of either during its formation, it takes it up. Perhaps the proportions are not far from equal parts of sulphur and of iron. It is of a pale yellow or brownish colour, and is capable of assuming a crystalline form. Its specific gravity is about 4,000. When placed upon the fire, it precipitates; and at a red heat loses its yellow colour, and becomes of an iron grey, excepting its surface, which is of a bright red. It melts at 102° Wedgewood in a covered crucible into a bluish slag, somewhat porous internally.‡ When exposed to air and moisture, the sulphur, as happens in all sulphurets, gradually absorbs oxygen, and is converted into an acid.

‡ *Kirwan's Miner.* ii. 76.

If iron filings and sulphur be mixed together, and formed into a paste with water, the sulphur decomposes the water, and absorbs oxygen so rapidly that the mixture takes fire, even though it be buried under ground. This phenomenon was first discovered by Homberg; and it is considered as affording an explanation of the origin of volcanoes. The native sulphuret of iron has been observed more than once to take fire on being suddenly moistened with water.

208 Phosphuret,

Iron combines readily with phosphorus, and forms *phosphuret of iron*; to which Bergman, who first discovered it, gave the name of *siderum*.

There is a particular kind of iron, known by the name of *cold short iron*, because it is brittle when cold, though it be malleable when hot. Bergman was employed

(R) Αυταρ Πηλειδης θηκεν σολον αυτοχοωνον,

Iron.

ployed at Upsal in examining the cause of this property, while Meyer was occupied at Stetin with the same investigation; and both of them discovered, nearly at the same time, that, by means of sulphuric acid, a white powder could be separated from this kind of iron, which by the usual process they converted into a metal of a dark steel grey, exceedingly brittle, and not very soluble in acids. Its specific gravity was 6,700; it was not so fusible as copper; and when combined with iron rendered it *cold short*. Both of them concluded that this substance was a new metal; and Bergman gave it the name of *siderum*. But Klaproth soon after recollecting that the salt composed of phosphoric acid and iron bore a great resemblance to the white powder obtained from cold short iron, suspected the presence of phosphoric acid in this new metal. To decide the point, he combined phosphoric acid and iron, and obtained, by heating it in a crucible along with charcoal powder (s), a substance exactly resembling the new metal. Meyer, when Klaproth communicated to him this discovery, informed him that he had already satisfied himself, by a more accurate examination, that siderum contained phosphoric acid. Soon after this, Scheele actually decomposed the white powder obtained from cold short iron, and thereby demonstrated, that it was composed of phosphoric acid and iron. The siderum of Bergman, however, is composed of phosphorus and iron, the phosphoric acid being deprived of its oxygen during the *reduction*; or it is phosphuret of iron. It may be formed by fusing in a crucible an ounce of phosphoric glass, an ounce of iron, and half a dram of charcoal powder. It is very brittle, and appears white when broken. When exposed to a strong heat, it melts, and the phosphorus is dissipated.* It may be formed also by melting together equal parts of phosphoric glass and iron-filings. Part of the iron combines with the oxygen of the phosphoric glass, and is vitrified; the rest forms the phosphuret, which sinks to the bottom of the crucible. It may be formed also by dropping small bits of phosphorus into iron-filings heated red hot‡. The proportions of the ingredients of this phosphuret have not yet been determined.

* Pelletier, Ann. de Chim. i. 104.

‡ Id. Ann. de Chim. xiii. 113.

109 And carburet of iron.

Iron likewise combines with carbon, and forms a *carburet*. Carburet of iron has been long known and used in the arts under the names of *plumbago* and *black lead*. It is of a dark iron grey or blue colour, and has something of a metallic lustre. It has a greasy feel, and blackens the fingers, or any other substance to which it is applied. It is found in many parts of the world, especially in England, where it is manufactured into pencils. It is not affected by the most violent heat as long as air is excluded, nor is it in the least altered by simple exposure to the air, or to water. Its nature was first investigated by Scheele; who proved, by a very ingenious analysis, that it could be converted almost wholly into carbonic acid gas, and that the small residuum was iron. It follows from this analysis, that it is composed of carbon and iron; for the carbon during its combustion had been converted into carbonic acid gas. By the subsequent experiments of Pelletier and other French chemists, it has been shewn to consist nearly of nine parts of carbon to one of iron.

110 Varieties of iron.

There are a great many varieties of iron, which artists distinguish by particular names; but all of them may be reduced under one or other of the three following states: *Wrought iron* (or simply *iron*), *steel*, and *cast* or *raw iron*.

111 Wrought iron.

Wrought Iron is the substance which we have been hitherto describing. As it has never yet been decompounded, we consider it when pure as a simple body; but it has seldom or never been found without some small mixture of foreign substances. These substances are either some of the other metals, or oxygen, carbon, or phosphorus.

112 Steel.

Steel is distinguished from iron by the following properties.

It is so hard as to be unmalleable while cold, or at least it acquires this property by being immersed while ignited into a cold liquid: for this immersion, though it has no effect upon *iron*, adds greatly to the hardness of *steel*.

It is brittle, resists the file, cuts glass, affords sparks with flint, and retains the magnetic virtue for any length of time.

It loses this hardness by being ignited and cooled very slowly.

It melts at above 130° Wedgewood. It is malleable when red hot, but scarcely so when raised to a white heat.

It may be hammered out into much thinner plates than iron. It is more sonorous; and its specific gravity, when hammered, is greater than that of iron.

By being repeatedly ignited in an open vessel, and hammered, it becomes *wrought iron*†.

† Dr Pearson on Wootz, Phil. Transf.

113 Cast iron.

Cast Iron is distinguished by the following properties:

It is scarcely malleable at any temperature. It is generally so hard as to resist the file. It can neither be hardened nor softened as steel can by ignition and cooling. It is exceedingly brittle. It melts at 130° Wedgewood. It is more sonorous than steel.*

* Ibid.

Cast iron is converted into wrought iron by exposing it for a considerable time in a furnace to a heat sufficiently strong to melt it. During the process it is constantly stirred by a workman, that every part of it may be equally exposed to the air. In about an hour the hottest part of the mass begins to heave and swell, and to emit a lambent blue flame. This continues nearly an hour; and by that time the conversion is completed. The heaving is evidently produced by the emission of an elastic fluid‡.

‡ Beddoes, Phil. Transf. 1791.

Wrought iron may be converted into steel by being kept for some hours in a strong red heat, surrounded with charcoal powder in a covered crucible. By this process, which is called *cementation*, the iron gains some weight.

114 Cause of these varieties.

These different kinds of iron have been long known, and the converting of them into each other has been practised in very remote ages. Many attempts have been made to explain the manner in which this conversion is accomplished. According to Pliny, steel owes its peculiar properties chiefly to the water into which it is plunged in order to be cooled§. Becher supposed that fire was the only agent; that it entered into the iron, and converted it into steel. Reaumur was the first who attended accurately to the process; and his numerous experiments have certainly contributed to elucidate the subject. He supposed that iron was converted into

§ Pliny, l. xxxiv. 14.

(s) This process in chemistry is called *reduction*.

to steel by combining with saline and oily or sulphureous particles, and that these were introduced by the fire. But it was the analysis of Bergman, published in 1781, that first paved the way to the explanation of the nature of these different species of iron.

By dissolving in diluted sulphuric acid 100 parts of cast iron, he obtained 40 ounce measures of hydrogen; from 100 parts of steel he obtained 48 ounce measures; and from 100 parts of wrought iron, 50 ounce measures. Now as the hydrogen is produced by the property which iron has of decomposing water and uniting with its oxygen, it is evident that the greater the quantity of hydrogen obtained, with the more oxygen does the iron combine. But the quantities of iron were equal; they ought therefore to have combined with equal quantities of oxygen. But it is evident, from the quantities of hydrogen obtained, that the cast iron received less oxygen than either of the other two: cast iron therefore must contain already some oxygen, since it requires less than the other two species in order to be saturated. Here then is one difference between cast iron and the other two kinds; it contains oxygen. Steel, on the contrary, does not appear to contain any oxygen. The difference between the quantity of hydrogen produced during its solution and that of wrought iron, which contains no oxygen, is exceedingly small, and it has been found to diminish in proportion to the purity of the steel.

From 100 parts of cast iron Bergman obtained 2,2 of plumbago, or $\frac{1}{45}$; from 100 parts of steel, 0,5, or $\frac{1}{200}$; and from 100 parts of wrought iron, 0,12, or $\frac{1}{900}$. Now plumbago is composed of $\frac{9}{10}$ths of carbon; cast iron therefore contains a considerable quantity of carbon, steel a smaller quantity, and wrought iron a very minute portion, which diminishes according to its purity, and would vanish altogether if iron could be obtained perfectly pure. Mr Grignon, in his notes on this analysis, endeavoured to prove, that plumbago was not essentially a part of cast iron and steel, but that it was merely accidentally present. But Bergman, after considering his objections, wrote to Morveau on the 18th November 1783. "I will acknowledge my mistake whenever Mr Grignon sends me a single bit of cast iron or steel which does not contain plumbago; and I beg of you, my dear friend, to endeavour to discover some such, and to send them to me; for if I am wrong, I wish to be undeceived as soon as possible."* This was almost the last action of the illustrious Bergman. He died a few months after at the age of 49, leaving behind him a most brilliant reputation, which no man ever more deservedly acquired. His industry, his indefatigable, his astonishing industry, would alone have contributed much to establish his name; his extensive knowledge would alone have attracted the attention of philosophers; his ingenuity, penetration, and accurate judgment, would alone have secured the applause; and his candour and love of truth procured him the confidence and the esteem of the world—But all these qualities were united in Bergman, and conspired to form one of the greatest men and noblest characters that ever adorned human nature.

* *Morveau, Encycl. Method. Chimie* i. 448.

The experiments of Bergman were fully confirmed by those of Morveau, Vandermonde, Monge, and Berthollet, who have likewise thrown a great deal of additional light on the subject. From all these experiments the following deductions may be made.

Wrought iron is a simple substance, and if perfectly pure would contain nothing but *iron*.

Steel is iron combined with carbon. The proportion of this last ingredient has not yet been ascertained; Dr Pearson fixes it at $\frac{1}{300}$th part at a medium. Steel, in consequence of its composition, has been called by some chemists *carburet of iron*; but before assigning it that name, which has been also given to plumbago, it ought to be determined what are the proportions of carbon and iron which saturate each other. Is it the proportion in which these two substances exist in steel, or that which forms plumbago? In the first case, plumbago is carburet of iron combined with carbon; in the second, steel is carburet combined with iron. Or is it some intermediate proportion? Till these points be determined, perhaps it would be better to continue the old names than to risk the imposing of false ones.

Cast iron is iron contaminated with various foreign substances, the proportions of which vary according to circumstances. These substances are chiefly oxyd of iron and carbon, and sometimes silica (T).

Bergman found a quantity of manganese in the iron and steel which he examined; but it appears from the experiments of Vauquelin, that his method of determining the presence of that metal was not accurate.

115
Vauquelin's analysis of steel.

Mr Vauquelin* has lately analysed four kinds of steel with great care, and contrived his processes with much ingenuity. The result of his analysis is as follows:

* *Jour. de Mines.* See *Nicholson's Journal*, i. 200.

First steel, composed of	Carbon,	-	0,00789
	Silica,	-	0,00315
	Phosphorus,		0,00345
	Iron,	-	0,98551
			1
Second steel, composed of	Carbon,	-	0,00683
	Silica,	-	0,00273
	Phosphorus		0,00827
	Iron,	-	0,98217
			1
Third steel, composed of	Carbon,	-	0,00789
	Silica,	-	0,00315
	Phosphorus,		0,00791
	Iron	-	0,98105
			1
Fourth steel, composed of	Carbon,	-	0,00631
	Silica,	-	0,00252
	Phosphorus,		0,01520
	Iron,	-	0,97597
			1

It cannot be concluded from these experiments, that all steel contains phosphorus and silica; far less that these substances enter necessarily into the composition of steel. This *may* be the case, and former analyses may not have been nice enough to detect it; but before it can be admitted, it must be shewn that these substances are always present in steel, and that it loses its essential properties when deprived of them.

(T) An earth which shall be described in the next chapter.

116 Alloys of iron.

Iron combines with moft metals.

1. The alloy of gold and iron is very hard, and might, according to Dr Lewis who examined it, be employed with advantage in forming cutting inftruments.

2 That iron combines with filver is certain, but hardly any thing is known about the nature of the compound.

3. Platinum is ufually found alloyed with iron. Dr Lewis did not fucceed in his attempts to unite thefe metals by fufion, but he melted together caft iron and platinum. The alloy was exceffively hard, and poffeffed ductility.

4. There is very little affinity between iron and mercury; they cannot therefore be amalgamated by fimple mixture, even with the affiftance of heat. Vogel affirms that he has produced an amalgam of iron by the following procefs; Pound one part of iron filings and two parts of alum in a mortar to a fine powder; then pour in two or three parts of mercury, and triturate till the fubftances be thoroughly mixed. Pour on a little water, and continue the trituration for about an hour. If then no particles of iron can be diftinguifhed, pour on a little more water to wafh out the alum, and then dry the amalgam. If particles of iron be perceptible, the trituration muft be continued till they difappear.*

* *Ann. de Chim.* vi. 39.

5. Iron may be united to copper by fufion, but not without confiderable difficulty. The alloy has been applied to no ufe.

117 Its affinities.

The affinities of iron, according to Bergman, are as follows:

Nickel,
Cobalt,
Manganefe,
Arfenic,
Copper,
Gold,
Silver,
Tin,
Antimony,
Platinum,
Bifmuth,
[illegible],
Mercury,
Sulphuret of alkali,
Carbon?
Phofphorus?
Sulphur?

Sect. VII. *Of Tin.*

The Phenicians were the firft of thofe nations which make a figure in ancient hiftory that were acquainted with *tin*. They procured it from Spain* and from Britain, with which nations they carried on a very lucrative commerce. At how early a period they imported this metal we may eafily conceive, if we recollect that it was in common ufe in the time of Mofes †.

* *Pliny*, l. 4. c. 34. and l. 34. c. 47.

† *Numbers* xxxi. 22.

118 Properties of tin;

Tin is of a greyifh white colour; it has a ftrong difagreeable tafte, and emits a peculiar fmell when rubbed.

It is very malleable; tin leaf, or *tinfoil* as it is called, is about $\frac{1}{1000}$th part of an inch thick, and it might be beat out into leaves as thin again if fuch were wanted for the purpofes of art. Its ductility, however, is exceedingly imperfect; for a tin wire $\frac{1}{10}$th of an inch in diameter, is capable of fupporting only 49 pounds without breaking ‡. It is very flexible, and produces a crackling noife when bended.

Its hardnefs is 6+. Its fpecific gravity is 7,291 †; after hammering, 7,299 ||.

It melts at the temperature 410°, according to Dr Lewis; according to the Dijon academicians, at 419°. When heated red hot in clofe veffels it fublimes. It cryftallizes in the form of a rhomboidal prifm.*

‡ *Macquer's Dictionary.*

† *Kirwan's Miner.* ii. 195.

|| *Briffon.*

* *Pajot. Jour. de Phyf.* xxxviii. 52.

119 Oxyds,

Tin unites very readily with oxygen. When heated in contact with air, its furface foon becomes covered with a grey pellicle; when this is taken off, another appears foon after; and in this manner the whole metal may be converted into a dirty grey powder, which is the *grey oxyd of tin*. It is compofed, according to Fourcroy, of 90 parts of tin and 10 of oxygen.

When tin is heated red hot in contact with air, it takes fire †, and burns with a very lively white flame, and is gradually fublimed. If the fublimate be examined, it is found to confift of a white powder; it is the *white oxyd of tin*. The white oxyd is perhaps never obtained quite pure by this procefs; it feems always to contain a mixture of *grey oxyd*: but it may be obtained pure by pouring nitric acid upon tin, and then drying it. That metal having a much ftronger attraction for oxygen than azot has, decompofes the acid with the greateft rapidity, and affumes the appearance of a white powder, which is the *white oxyd*. This oxyd poffeffes many of the properties of an acid, and is therefore often called *ftannic acid*. It feems to confift of about 77 parts of tin and 23 of oxygen ‡.

† *Geoffroy.*

‡ *Kirwan's Miner.* ii. 488.

The affinities of the grey oxyd of tin, according to Bergman, are as follows:

Pyromucous acid,*
Sebacic acid,
Tartaric,
Muriatic,
Sulphuric,
Oxalic,
Arfenic,
Phofphoric,
Nitric,
Succinic,
Fluoric,
Saccholactic,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Pruffic.

* *Schrickel.*

120 Sulphurets,

Tin combines readily with fulphur. This fulphuret may be formed by fufing the two ingredients together. It is brittle, heavier than tin, and not fo fufible. It is of a bluifh colour and lamellated ftructure, and is capable of cryftallizing. According to Bergman, it is compofed of 80 parts of tin and 20 of fulphur; according to Pelletier, of 85 parts of tin and 15 of fulphur.*

Sulphur likewife combines with the white oxyd of tin, by mixing them together, and applying a gentle heat.† This compound has been called *aurum mufivum*. It is a mafs confifting of beautiful gold coloured flakes, and is ufed as a paint. It is compofed of about 40 parts of fulphur and 60 of white oxyd of tin ‡. The procefs for making this fubftance was formerly very complicated. Pelletier firft demonftrated its real compofition, and

* *Ann. de Chim.* xiii. 287.

† *Pelletier. Ibid.* p. 297.

‡ *Ibid.* 293.

Tin.

and was hence enabled to make many important improvements in the manner of manufacturing it ‖.

‖ See his *Memoire, Ann. de Chim.* xiii. 280.

Phoſphorus is eaſily combined with tin, by melting in a crucible equal parts of filings of tin and phoſphoric glaſs. Tin has a greater affinity for oxygen than phoſphorus has. Part of the metal therefore combines with

121 Phoſphuret,

the oxygen of the glaſs during the fuſion, and flies off in the ſtate of an oxyd, and the reſt of the tin combines with the phoſphorus. The phoſphuret of tin may be cut with a knife; it extends under the hammer, but ſeparates in laminæ. When newly cut it has the colour of ſilver; its filings reſemble thoſe of lead. When theſe filings are thrown on burning coals, the phoſphorus takes fire. This phoſphuret may likewiſe be formed by dropping phoſphorus gradually into melted tin. According to Pelletier, to whoſe experiments we are indebted for the knowledge of all the phoſphurets, it is compoſed of about 85 parts of tin, and 15 of phoſphorus*. Margraf alſo formed this phoſphuret, but he was ignorant of its compoſition.

* *Ann. de Chim.* xiii. 116.

122 Alloys,

Tin does not ſeem capable of combining with carbon. It is capable of combining with moſt of the metals.

1. It mixes readily with gold by fuſion; but the proportions in which theſe metals combine chemically are ſtill unknown. When one part of tin, and twelve of gold are melted together, the alloy is brittle, hard, and bad coloured. Twenty-four parts of gold and one of tin, produce a pale coloured alloy, harder than gold, but poſſeſſed of conſiderable ductility. Gold alloyed with no more than $\frac{1}{17}$th of tin is ſcarcely altered in its properties, according to Mr Alchorne†; but Mr Tillet, who has lately examined this alloy, found that whenever it was heated, it broke into a number of pieces.

† *Alchorne, Phil. Tranſ.*

2. The alloy of ſilver and tin is hardly known. According to Gellert and ſucceeding chemiſts, it is exceedingly brittle.

3. The alloy of platinum and tin is very fuſible and brittle, at leaſt when theſe metals are mixed in equal proportions‡.

‡ *Dr Lewis.*

4. Mercury diſſolves tin very readily, by being poured on it when melted. This amalgam cryſtallizes in the form of cubes, according to Daubenton; but according to Sage, in grey brilliant ſquare plates, thin towards the edges, and attached to each other ſo that the cavities between them are polygonal. It is compoſed of three parts of mercury and one of tin. The amalgam of tin is uſed to ſilver the backs of glaſs mirrors.

5. Tin unites very readily with copper, and forms alloys known by the names of *bronze* and *bell-metal*. The proportions of the ingredients cannot eaſily be aſſigned, perhaps becauſe the alloy has an affinity both for copper and tin. The ſpecific gravity of the alloy in all proportions is greater than the mean ſpecific gravity of the two metals ſeparately. When the quantity of tin is ſmall compared to that of the copper, $\frac{1}{10}$th for inſtance, the alloy is called *bronze*: it is brittle, yellow, and much heavier than copper; much more fuſible, and leſs liable to be altered by expoſure to the air. It was this alloy which the ancients uſed for ſharp edged inſtruments before the method of working iron was brought to perfection. The χαλκος of the Greeks, and perhaps the *æs* of the Romans, was nothing elſe. Even their copper coins contain a mixture of tin*.

* See *Dizé's Analyſis, Jour. de Phyſ.* 1790.

6. Tin ſeems capable of being united to iron by fuſion. That there is an affinity between theſe metals is evident from their adheſion when iron is dipt into melted tin. This is the method of making *tinplate*.

Tin ‖ Lead.

123 And affinities of tin.

The affinities of tin, according to Bergman, are as follows:

Zinc,
Mercury,
Copper,
Antimony,
Gold,
Silver,
Lead,
Iron,
Manganeſe,
Nickel,
Arſenic,
Platinum,
Biſmuth,
Cobalt,
Sulphuret of alkali,
Oxygen?
Sulphur?
Phoſphorus?

SECT. VIII. *Of Lead.*

LEAD appears to have been very early known. It is mentioned ſeveral times by Moſes. The ancients ſeem to have conſidered it as nearly related to tin.

124 Properties of lead.

Lead is of a bluiſh white colour, ſomewhat darker than tin. When newly melted it is very bright, but ſoon becomes tarniſhed by expoſure to the air. It has ſcarcely any taſte, but emits on friction a peculiar ſmell.

It is very malleable, and may be reduced to thin plates by the hammer; but its ductility is very imperfect: a wire of lead $\frac{1}{10}$th of an inch in diameter is only capable of ſupporting a weight of 29¼ pounds.*.

Its hardneſs is 5†; its ſpecific gravity is 11,3523‡ Its ſpecific gravity is not increaſed by hammering, neither does it become harder, as is the caſe with other metals: a proof that the hardneſs which metals aſſume under the hammer is in conſequence of an increaſe of denſity.

* *Macquer's Dictionary.*
† *Kirwan's Miner.* ii. 202.
‡ *Briſſon.*

It melts, according to Dr Lewis, at 540° Farenheit; according to the Dijon academicians, at 549°. When expoſed to a violent heat, it evaporates completely.

When cooled ſlowly, after being fuſed, it cryſtallizes. The Abbé Mongez obtained it in quadrangular pyramids lying on one of their ſides. Each pyramid was compoſed as it were of three layers. Pajot obtained it in the form of a polyhedron with 32 ſides, formed by the concourſe of ſix quadrangular pyramids†.

† *Jour. Phyſ.* xxxviii. 53.

Lead ſtains paper or the fingers of a bluiſh black colour.

125 Its oxyds.

There is a ſtrong affinity between this metal and oxygen. When nitric acid is poured upon it, an effervеſcence enſues, owing to the decompoſition of the acid; the lead ſeizes oxygen from it, and is converted into a white powder, which may be obtained pure by evaporating it to dryneſs, and then waſhing it in pure water. This is the *white oxyd of lead*. It is compoſed of about 95 parts of lead, and five of oxygen‡. The affinities of this oxyd are, according to Bergman, as follows:

‡ *Kirwan's Miner.* ii. 499.

Sulphuric acid,
Sebacic,
Saccholactic,
Oxalic,

Arſenic,

Lead.

Arſenic,
Tartarous,
Phoſphoric,
Muriatic,
Benzoic (u)?
Sulphurous,
Suberic ?} (v)
Zoonic ? }
Nitric,
Pyromucous (v)?
Fluoric,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Pruſſic,
Carbonic,
Fixed alkali.

When lead is expoſed to heat in contact with air, its ſurface is ſoon covered with a grey pellicle; when this is taken off, another ſoon forms: and in this manner, the whole lead may ſoon be converted into a dirty grey powder, which ſeems to be the white oxyd mixed with a little lead. When this powder is heated red hot, it aſſumes a deep yellow colour. This is the *yellow oxyd* of lead, formerly called *maſſicot*. If the heat be continued, the colour is gradually changed to a beautiful red. This is the *red oxyd of lead*, formerly called *minium*. It is compoſed, as Lavoiſier has ſhewn, of 88 parts of lead and 12 of oxygen*.

* *Mem. Par.* 1781.

The manner in which theſe changes are brought about is evident; the metal gradually abſorbs oxygen from the atmoſphere. This has been actually proved by experiment. Theſe oxyds (if they really differ in the proportion of oxygen) reſemble acids in ſeveral of their properties. They are very eaſily converted into glaſs by fuſion. Scheele has ſhewn that there is alſo a *brown oxyd of lead*, which contains more oxygen than any of the others.

126 Sulphuret,

Sulphur unites eaſily to lead by fuſion. The ſulphuret of lead is brittle, of a deep grey colour, and much leſs fuſible than lead. Theſe two ſubſtances are often found naturally combined; the compound is then called *galena*. Sulphuret of lead is compoſed, according to the experiments of Wenzel, of 868 parts of lead, and 132 of ſulphur†.

† *Kirwan's Miner.* ii. 492.

127 Phoſphuret,

Phoſphuret of lead may be formed by mixing together equal parts of filings of lead and phoſphoric glaſs, and fuſing them in a crucible. It may be cut with a knife, but ſeparates into plates when hammered. It is of a ſilver white colour with a ſhade of blue, but it ſoon tarniſhes when expoſed to the air. This phoſphuret may alſo be formed by dropping phoſphorus into melted lead. It is compoſed of about 12 parts of phoſphorus and 88 of lead‡.

‡ *Pelletier, Ann. de Chim.* xiii. 114.

Lead combines with moſt of the other metals.

128 Alloys, and

1. Little is known concerning the alloy of lead and gold. It is ſaid to be brittle.

2. The alloy of ſilver and lead is very fuſible, and neither elaſtic nor ſonorous.

3. Platinum and lead unite in a ſtrong heat: the alloy is brittle, of a purpliſh colour, and ſoon changes on expoſure to the air§.

§ *Fourcroy.*

4. Mercury, when poured upon melted lead, diſſolves it readily. The amalgam is white and brilliant, and aſſumes a ſolid form. It is capable of cryſtallizing. The cryſtals are compoſed of one part of lead and one and a half of mercury.‖

‖ *Dijon Academicians.*

5. Copper and lead combine eaſily by fuſion; but the alloy has not been applied to any uſe.

6. Iron does not unite with lead.

7. Lead and tin may be combined by fuſion. The alloy in the proportion of two parts of lead, and one of tin, is more ſoluble than either of the metals ſeparately. It is accordingly uſed by plumbers as a ſolder.

129 Affinities.

Lead, when taken internally, acts as a poiſon. Its affinities, according to Bergman, are as follows:

Gold,
Silver,
Copper,
Mercury,
Biſmuth,
Tin,
Antimony,
Platinum,
Arſenic,
Zinc,
Nickel,
Iron,
Sulphuret of alkali,
Sulphur,
Phoſphorus?

130 Names and marks given to the metals by the ancients.

The ancients gave to the ſeven metals laſt deſcribed (omitting *platinum*, which they did not know) the names of the planets, and denoted each of them by particular marks, which repreſented both the planet and the metal.

Gold was the	Sun, and repreſented by	☉.
Silver the	Moon,	☾.
Mercury	Mercury,	☿.
Copper	Venus,	♀.
Iron	Mars,	♂.
Tin	Jupiter,	♃.
Lead	Saturn,	♄.

It ſeems moſt probable that theſe names were firſt given to the planets; and that the ſeven metals, the only ones then known, were ſuppoſed to have ſome relation to the planets or to the gods that inhabited them, as the number of both happened to be the ſame. It appears from a paſſage in Origen, that theſe names firſt aroſe among the Perſians (w). Why each particular metal

(u) Benzoat of lead is decompoſed by muriatic acid. *Trommſdorf, Ann. de Chim.* xi. 317.

(v) Suberic acid decompoſes nitrat of lead. See *Jameſon's Mineralogy*, p. 166. Zoonic acid produces the ſame effect, as Berthollet has obſerved.

(v) Schrikel places it after the three mineral acids.

(w) *Contra Celſum*, lib. vi. 22.—" Celſus de quibuſdam Perſarum myſteriis ſermonem facit. Harum rerum, inquit, aliquod reperitur in Perſarum doctrina Mithraciſque eorum myſteriis veſtigium. In illis enim duæ cœleſtes converſiones, alia ſtellarum fixarum, errantium alia, et animæ per eas tranſitus quodam ſymbolo repræſentantur, quod

Lead. metal was denominated by a particular planet it is not easy to see. Many conjectures have been made, but scarcely any of them are satisfactory.

131 Origin of these marks according to the astrologers;

As to the characters by which these metals were expressed, astrologers seem to have considered them as the attributes of the deities of the same name. The circle in the earliest periods among the Egyptians was the symbol of divinity and perfection; and seems with great propriety to have been chosen by them as the character of the sun, especially as, when surrounded by small strokes projecting from its circumference, it may form some representation of the emission of rays. The semicircle is, in like manner, the image of the moon; the only one of the heavenly bodies that appears under that form to the naked eye. The character ♄ is supposed to represent the scythe of Saturn; ♃ the thunderbolts of Jupiter; ♂ the lance of Mars, together with his shield; ♀ the looking-glass of Venus; and ☿ the caduceus or wand of Mercury.

132 According to the alchemists.

The alchemists, however, give a very different account of these symbols. Gold was the most perfect metal, and was therefore denoted by a circle. Silver approached nearest it; but as it was inferior, it was denoted only by a semicircle. In the character ☿ the adepts discovered gold with a silver colour. The cross at the bottom expressed the presence of a mysterious something, without which mercury would be silver or gold. This something is combined also with copper; the possible change of which into gold is expressed by the character ♀. The character ♂ declares the like honourable affinity also; though the semicircle is applied in a more concealed manner: for, according to the properest mode of writing, the point is wanting at the top, or the upright line ought only to touch the horizontal, and not to interfect it. Philosophical gold is concealed in steel; and on this account it produces such valuable medicines. Of tin, one half is silver, and the other consists of the unknown something; for this reason the cross with the half moon appears in ♃. In lead this something is predominant, and a similitude is observed in it to silver. Hence in its character ♄ the cross stands at the top, and the silver character is only suspended on the right hand behind it.

133 Their real origin.

The fact, however, according to Professor Beckmann, from whom most of the above remarks have been taken, seems to be, that these characters are mere abbreviations of the old names of the planets. "The character of Mars (he observes*), according to the oldest mode of representing it, is evidently an abbreviation of the word Θουρος, under which the Greek mathematicians understood that deity; or, in other words, the first letter Θ, with the last letter ς placed above it. The character of Jupiter was originally the initial letter of Ζευς; and in the oldest manuscripts of the mathematical and astrological works of Julius Firmicus, the capital Z only is used, to which the last letter ς was afterwards added at the bottom, to render the abbreviation more distinct. The supposed looking-glass of Venus is nothing else than the initial letter distorted a little of the word Φωσφορος, which was the name of that goddess. The imaginary scythe of Saturn has been gradually formed from the two first letters of his name Κρονος, which transcribers, for the sake of dispatch, made always more convenient for use, but at the same time less perceptible. To discover in the pretended caduceus of Mercury the initial letter of his Greek name Στιλβων, one needs only look at the abbreviations in the oldest manuscripts, where they will find that the Σ was once written as C; they will remark also that transcribers, to distinguish this abbreviation from the rest still more, placed the C thus ◡, and added under it the next letter τ. If those to whom this deduction appears improbable will only take the trouble to look at other Greek abbreviations, they will find many that differ still farther from the original letters they express than the present character ☿ from the C and τ united. It is possible also that later transcribers, to whom the origin of this abbreviation was not known, may have endeavoured to give it a greater resemblance to the caduceus of Mercury. In short, it cannot be denied that many other astronomical characters are real symbols, or a kind of proper hieroglyphics, that represent certain attributes or circumstances, like the characters of Aries, Leo, and others quoted by Saumise."

* *History of Inventions, English translation*, iii. 67.

Sect. IX. *Of Zinc.*

Zinc. The ancients were acquainted with a mineral to which they gave the name of *Cadmea*, from Cadmus, who first taught the Greeks to use it. They knew that when melted with copper it formed brass; and that when burnt, a white spongy kind of ashes was volatilised, which they used in medicine*. This mineral contained a good deal of zinc; and yet there is no proof remaining that the ancients were acquainted with that metal (x). It is first mentioned in the writings of Albertus Magnus, who died in 1280; but whether he had seen it is not so clear, as he gives it the name of *marcasite of gold*, which implies,

134 Discovery of zinc.

* *Pliny*, l. 34. c. 2. and 10.

quod hujusmodi est. Scala altas portas habens, in summa autem octava porta. Prima portarum plumbea, altera stannea, tertia ex ære, quarta ferrea, quinta ex ære mixto, sexta argentea, septima ex auro. κλιμαξ ὑψιπυλος, επι δ' αιτῃ πυλη ογδοη. Ἡ πρωτη των πυλων μολιβδου, ἡ δευτερα κασσιτερου, ἡ τριτη χαλκου, ἡ τεταρτη σιδηρου, ἡ πεμπτη καρασου νομισματος, ἡ εκτη αργυρου, χρυσου δ' ἡ ἑβδομη. Primum assignant Saturno tarditatem illius sideris plumbo indicantes: alteram Veneri, quam referunt, ut ipsi quidem putant stanni splendor et mollities; tertiam Jovi, aheneam illam quidem et solidam: quartam Mercurio, quia Mercurius et ferrum, uterque operum omnium tolerantes, ad mercaturam utiles, laborum patientissimi. Marti quintam, inæqualem illam et variam propter mixturam. Sextam, quæ argentea est, lunæ; septimam auream soli tribuunt, quia solis et lunæ colores hæc duo metalla referunt."

Borrichius suspects, with a good deal of probability, that the names of the gods in this passage have been transposed by transcribers, either through ignorance or design. He arranges them as follows: "Secundam portam faciunt Jovis, comparantes ei stanni splendorem et mollitiem; tertiam Veneris æratam et solidam; quartam Martis, est enim laborum patiens, æque ac ferrum, celebratus hominibus; quintam Mercurii propter misturam inæqualem ac variam, et quia negotiator est; sextam Lunæ argenteam; septimam Solis auream." *Ol. Borrichius de ortu et progressu chemiæ.* Hafniæ, 1668, 4to. p. 29.

(x) Grignon indeed says, that something like it was discovered in the ruins of an ancient Roman city in Champagne; but the substance which he took for it was not examined with any accuracy. It is impossible therefore to draw any inference whatever from his assertion. *Bulletin des fouilles d'une ville Romaine.* p. 11.

Zinc.

implies, one would think, that it had a yellow colour (Y). The word *zinc* occurs first in the writings of Paracelsus, who died in 1541. He informs us very gravely, that it is a metal, and not a metal, and that it consists chiefly of the ashes of copper†. This metal has also been called *spelter*.

† See *Vol.* 6. *of his Works in* 4to.

Zinc has never been found in Europe in a state of purity, and it was long before a method was discovered of extracting it from its ore (Z). Henkel pointed out one in 1721, and Von Swab obtained it by distillation in 1742, and Margraf published a process in the Berlin Memoirs in 1746‡.

‡ *Bergman*, ii. 309.

135
Properties of zinc.

It is of a bluish white colour, somewhat lighter than lead. It has neither taste nor smell.

It has some degree of malleability; for by compression it may be reduced into thin plates§; but it cannot be drawn out into wire. It is more brittle when hot than when cold.

§ *Sage*.

Its hardness is 6*. Its specific gravity, when compressed, is 7,1908†; in its usual state, 6,862‡. It melts at about 699° Fahrenheit§.

* *Kirwan's Miner.* ii. 232.
† *Brisson.*
‡ *Kirwan, ibid.*
§ *Bergman.*

When allowed to cool slowly, it crystallizes in small bundles of quadrangular prisms, disposed in all directions. If they are exposed to the air while hot, they assume a blue changeable colour*.

* *Mongez.*

136
Its oxyds,

When zinc is kept melted in contact with air, it becomes covered with a grey pellicle, which gradually assumes a yellowish tint. By removing this pellicle from time to time, the whole of the metal may be reduced into a grey powder. This is the *grey oxyd of zinc*. This oxyd is probably composed of about 85 parts of zinc and 15 of oxygen†. When zinc is violently heated, it burns with a bright white flame, and at the same time a quantity of very light white flakes are sublimed. These flakes are the *white oxyd of zinc*, which contains a good deal more oxygen than the grey oxyd (A).

† *Morveau, Kirwan's Miner.* ii. 489.

Zinc may also be oxydated by solution in acids, particularly the nitric acid. Whether the oxyd obtained by precipitating zinc from its solution in that acid, or by distilling that acid off zinc, be really different from the white oxyd, has not yet been properly ascertained; but one would be apt to suspect, from the experiments mentioned by Mr Kirwan, that it contained a good deal more oxygen‖.

‖ *Mineral* ii. 499.

The affinities of the oxyds, or rather of the white oxyd of zinc, are, according to Bergman, as follows:

Oxalic acid,
Sulphuric,
Pyromucous*,
Muriatic,
Saccholactic,
Nitric,
Sebacic,
Tartaric,
Phosphoric,
Citric,
Succinic,
Fluoric,
Arsenic,
Formic,
Lactic,
Acetous,
Boracic,
Prussic,
Carbonic,
Ammonia.

* *Schrickel.*

137
Sulphuret,

There is an affinity between sulphur and zinc, as is evident from these two substances being often found united; but it is very difficult to form the sulphuret of zinc artificially, on account of the rapid oxydation and consequent volatilization of the zinc. Morveau, however, succeeded in forming it.

138
Phosphurets,

Zinc may be combined with phosphorus, by dropping small bits of phosphorus into it while in a state of fusion. Pelletier, to whom we are indebted for the experiment, added also a little resin, to prevent the oxydation of the zinc. Phosphuret of zinc is of a white colour, a metallic splendor, but resembles lead more than zinc. It is somewhat malleable. When hammered or filed, it emits the odour of phosphorus. When exposed to a strong heat, it burns like zinc*.

* *Ann. de Chim.* xiii, 129.

Phosphorus

(Y) The passages in which he mentions it are as follows:—*De Mineral.* lib. ii. cap. 11. "Marchasita, sive marchasida ut quidam dicunt, est lapis in substantia, et habet multas species, quare colorem accipit cujuslibet metalli, et sic dicitur marchasita argentea et aurea, et sic dicitur aliis. Metallum tamen quod colorat eum non distillat ab ipso, sed evaporat in ignem, et sic relinquitur cinis inutilis, et hic lapis notus est apud alchimicos, et in multis locis veniuntur.

Lib. iii. chap. 10. "Æs autem invenitur in venis lapidis, et quod est apud locum qui dicitur Goselaria est purissimum et optimum, et toti substantiæ lapidis incorporatum, ita quod totus lapis est sicut marchasita aurea, et profundatum est melius ex eo quod purius.

Lib. v. cap. 5. "Dicimus igitur quod marchasita duplicem habet in sui creatione substantiam, argenti vivi scilicet mortificati, et ad fixionem approximantis, et sulphuris adurentis. Ipsam habere sulphureitatem comperimus manifesta experientia. Nam cum sublimatur, ex illa emanat substantia sulphurea manifesta comburens. Et sine sublimatione similiter perpenditur illius sulphureitas.

"Nam si ponatur ad ignitionem, non suscipit illam priusquam inflammatione sulphuris inflammetur, et ardeat. Ipsam vero argenti vivi substantiam manifestatur habere sensibiliter. Nam albedinem præstat Veneri meri argenti, quemadmodum et ipsum argentum vivum, et colorem in ipsius sublimatione cælestium præstare, et luciditatem manifestam metallicam habere videmus, quæ certum reddunt artificem Alchimiæ, illam has substantias continere in radice sua."

(Z) The real discoverer of this method appears to have been Dr Isaac Lawson. See *Pott*, III. diss. 7. and *Watson's Chemical Essays*.

(A) Pott observed, that it was $\frac{1}{10}$th heavier than the zinc from which it was obtained; and Mr Boyle had long before ascertained the same fact.—*Shaw's Boyle*, II. 391, 394.

This oxyd of zinc was well known to the ancients. Dioscorides describes the method of preparing it. The ancients called it *pompholyx*, the early chemists gave it the name of *lana philosophica*. Dioscorides compares it to wool, εριων τολυπαις αφομοιουνται, v. 85. p. 352.

Zinc.

Phosphorus combines also with the oxyd of zinc, a compound which Margraf had obtained during his experiments on phosphorus. When 12 parts of oxyd of zinc, 12 parts of phosphoric glass, and two parts of charcoal powder, are distilled in an earthen ware retort, and a strong heat applied, a metallic substance sublimes of a silver-white colour, which when broken has a vitreous appearance. This, according to Pelletier, is phosphuret of oxyd of zinc. When heated by the blowpipe, the phosphorus burns, and leaves behind a glass transparent while in fusion, but opaque after cooling †.

† Pelletier, ibid. 128.

139 Carburet,

Zinc also combines with carbon, and forms carburet of zinc. The French chemists have shewn that zinc generally contains some carbon.

140 Alloys,

Zinc combines with most of the metals:

1. It mixes with gold in any proportion. The alloy is the whiter and the more brittle the greater quantity of zinc it contains. An alloy, consisting of equal parts of these metals, is very hard and white, receives a fine polish, and does not tarnish readily. It has therefore been proposed by Mr Malouin ‡ as very proper for the specula of telescopes. One part of zinc is said to destroy the ductility of 100 parts of gold ‖.

‡ Mem. Acad. Par. 1742.

‖ Keir's Macquer's Dictionary.

2. The alloy of silver and zinc is easily produced by fusion. It is brittle.

3. Platinum combines very readily with zinc. The alloy is brittle, pretty hard, very fusible, of a bluish white colour, not so clear as that of zinc.*

* Dr Lewis.

4. Zinc may be combined with mercury by fusion. The amalgam is solid. It crystallizes when melted and cooled slowly into lamellated hexagonal figures, with cavities between them. They are composed of one part of zinc and two and a half of mercury †. It is used to rub on electrical machines, in order to excite electricity.

† Elemens de Chim. Dijon, t. 3.

5. Zinc combines very readily with copper. This alloy, which is called *brass*, was known to the ancients. They used an ore of zinc to form it which they called *cadmia*. This alloy was very much valued by the ancients. Dr Watson has proved that it was to brass which they gave the name of *orichalcum*.* Their *æs* was copper or rather bronze (B). Brass is composed of about three parts of copper and one of zinc. It is of a beautiful yellow colour, more fusible than copper, and not so apt to tarnish. It is malleable, and so ductile that it may be drawn out into wire. When the alloy contains three parts of zinc and four of copper, it assumes a colour nearly the same with gold, but it is not so malleable as brass. It is then called *pinchbeck*, *prince's metal* or *Prince Rupert's metal*.

* Manchester Transf. vol. ii.

6. The alloy of iron and zinc has scarcely been examined: but Malouin has shewn that zinc may be used instead of tin to cover iron plates; a proof that there is an affinity between the two metals ‡.

Antimony.

‡ Mem. Par. 1742.

7. Tin and zinc combine easily. The alloy is harder than tin. This alloy is often the principal ingredient in the compound called *pewter*.

8. Mr Gmelin has succeeded in forming an alloy of zinc and lead by fusion. He put some suet into the mixture, and covered the crucible, in order to prevent the evaporation of the zinc. When the zinc exceeded the lead very much, the alloy was malleable, and much harder than lead. A mixture of two parts of zinc and one of lead formed an alloy more ductile and harder than the last. A mixture of equal parts of zinc and lead formed an alloy differing little in ductility and colour from lead; but it was harder, and more susceptible of polish, and much more sonorous. When the mixture contained a smaller quantity of zinc, it still approached nearer the ductility and colour of lead, but it continued harder, more sonorous, and susceptible of polish, till the proportions approached to one of zinc and 16 of lead, when the alloy differed from the last metal only in being somewhat harder.*

* Ann. de Chim. ix. 95.

141 And affinities.

The affinities of zinc, according to Bergman, are as follows:

Copper,
Antimony,
Tin,
Mercury,
Silver,
Gold,
Cobalt,
Arsenic,
Platinum,
Bismuth,
Lead,
Nickel,
Iron.

Sect. X. *Of Antimony.*

The ancients were acquainted with an oxyd of antimony to which they gave the names of στιμμι and *stibium*. Pliny* informs us, that it was found in silver ore; and we know that at present there are silver ores † in which it is contained. It was used as an external application to sore eyes; and Pliny gives us the method of preparing it ‡. Galen supposes that the τετραγωνον of Hippocrates was a preparation of antimony; but this wants proof. It does not appear, however, that the ancients considered this substance as a metal, or that they knew antimony in a state of purity (C). Who first extracted it from its ore we do not know; but Basil Valentine, a chemist of the 16th century, is the first who describes

* Pliny, l. xxxiii. c. 6.

† Kirwan's Miner. ii. 110.

‡ Pliny, ibid.

142 Discovery of antimony.

(B) The ancients do not seem to have known accurately the difference between copper, brass, and bronze. Hence the confusion observable in their names. They considered brass as only a more valuable kind of copper, and therefore often used the word *æs* indifferently to denote either. It was not till a late period that mineralogists began to make the distinction. They called copper *æs cyprium*, and afterwards only *cyprium*, which in process of time was converted into *cuprum*. When these changes took place is not known accurately. Pliny uses *cyprium*, lib. xxxvi. c. 26. The word *cuprum* occurs first in Spartian, who lived about the year 290. He says in his life of Caracalla, *cancelli ex ære vel cupro*.

(C) Mr Roux indeed, who at the request of Count Caylus analysed an ancient mirror, found it composed of copper, lead and antimony. This would go far to convince us that the ancients knew this metal, provided it could be proved that the mirror was *really* an ancient one; but this point appears to be extremely doubtful.

Antimony. describes the process. To him indeed we are indebted for our acquaintance with many of the properties of this metal.

Antimony is of a white colour, with a shade of grey. It has a sensible taste, but no smell ‖.

‖ *Fourcroy.*

143 Properties of antimony.

It is neither malleable nor ductile, but exceedingly brittle. Its specific gravity, according to Brisson, is 6,702; according to Bergman, 6,860. Its hardness is 6,5 §. It melts at 809° Fahrenheit ¶. If after this the heat be increased, the metal evaporates. On cooling it assumes the form of oblong crystals, perpendicular to the internal surface of the vessel in which it cools. It is to this crystallization that the laminated structure which antimony always assumes is owing.

§ *Kirwan's Miner.* ii. 244.
¶ *Bergman.*

144 Its oxyds,

Neither air nor water have much effect on this metal. When antimony is beat to powder, and exposed for some time to a gentle heat, it absorbs oxygen, and is converted into a grey powder. This is the *grey oxyd of antimony*. When this metal is kept for some time melted in contact with air, it sublimes in the form of a white powder, formerly called *snow* or *white flowers of antimony*. This is the *white oxyd of antimony*. This oxyd may be procured also by pouring nitric acid on antimony, and then evaporating to dryness. Antimony attracts the oxygen from the acid, and thus passes very rapidly into the state of an oxyd. This oxyd seems to consist of about 77 parts of antimony and 23 of oxygen.* The nature of these oxyds has never yet been accurately inquired into. It is not even known at present whether the white oxyd obtained by heat and that obtained by nitric acid contain the same quantity of oxygen. The experiments mentioned by Mr Kirwan make the contrary probable †; and yet these oxyds have too many qualities in common to render these experiments conclusive. The white oxyd of antimony is soluble in water ‡; and when fused, is converted into a transparent glass. The white oxyd obtained by nitric acid seems to possess many of the properties of an acid.

* *Kirwan's Miner.* ii. 489.
† *Ibid.*
‡ *Rouelle.*

The affinities of the grey oxyd of antimony are, according to Bergman, as follows:

Sebacic acid,
Muriatic,
Benzoic (D)?
Oxalic,
Sulphuric,
Pyromucous §,
Nitric,
Tartarous,
Saccholactic,
Phosphoric,
Citric,
Succinic,
Fluoric,
Arsenic,
Formic,
Lactic,
Acetous,
Boracic,
Prussic,
Carbonic.

§ *Schrickel.*

145 Sulphurets,

Sulphur combines readily with antimony. This compound is often found native: it was formerly called antimony, and the pure metal was then called *regulus of antimony*. Sulphuret of antimony is easily melted by a moderate heat: if the heat be continued, the sulphur sublimes, and at the same time the antimony absorbs oxygen, and is converted into a grey oxyd. This sulphuret is composed of 74 parts of antimony and 26 of sulphur.*

* *Bergman*, iii. 167.

The grey oxyd of antimony is also capable of combining with about $\frac{4}{100}$ of sulphur. This compound, by fusion, may be converted into glass. It was formerly used in medicine under the name of *glass of antimony*.

146 Phosphuret,

When equal parts of antimony and phosphoric glass are mixed together with a little charcoal powder, and melted in a crucible, phosphuret of antimony is produced. It is of a white colour, brittle, appears laminated when broken, and at the fracture there appear a number of small cubic facettes. When melted it emits a green flame, and then sublimes in the form of a white powder. Phosphuret of antimony may likewise be prepared by fusing equal parts of antimony and phosphoric glass, or by dropping phosphorus into melted antimony †.

† *Pelletier, Ann. de Chim.* xiii. 132.

Antimony is capable of combining with most of the metals.

147 Alloys,

1. Gold may be alloyed with antimony by fusing them together. The antimony is afterwards separable by an intense heat. This alloy is little known, and has never been applied to any use.

2. The alloy of silver and antimony is brittle, and its specific gravity, as Gellert has observed, is greater than intermediate between the specific gravities of the two metals which enter into it.

3. Platinum easily combines with antimony. The alloy is brittle, and much lighter than platinum.* The antimony cannot afterwards be completely separated by heat.

* *Dr Lewis.*

4. Mercury does not easily combine with antimony. Mr Gellert succeeded in amalgamating this metal by putting it into hot mercury, and covering the whole with water.

5. Copper combines readily with antimony by fusion. The alloy is of a beautiful violet colour, and its specific gravity is greater than intermediate †.

† *Gellert.*

6. Iron combines with antimony, and forms a brittle hard alloy, the specific gravity of which is less than intermediate. The magnetic quality of iron is much more diminished by being alloyed with antimony than with any other metal ‡.

‡ *Id.*

7. The alloy of tin and antimony is white and brittle; its specific gravity is less than intermediate §.

§ *Id.*

8. When equal quantities of lead and antimony are fused, the alloy is porous and brittle: three parts of lead and one of antimony form a compact alloy, malleable, and much harder than lead: 12 parts of lead and one of antimony form an alloy very malleable, and a good deal harder than lead: 16 parts of lead and one of antimony form an alloy which does not differ from lead except in hardness ¶. This alloy forms printers types.

¶ *Gmelin, Ann. de Chim.* viii. 319.

9. Zinc and antimony form a brittle alloy, the specific gravity of which is less than intermediate.* The alloys of antimony are little known. Gellert is almost the

* *Gellert.*

(D) Muriatic acid decomposes benzoat of antimony. *Trommsdorf, Ann. de Chim.* xi. 317.

the only perſon who has examined them. It would require a great number of experiments to be able to fix the proportions of their ingredients.

The affinities of antimony are, according to Bergman, as follows:

Iron,
Copper,
Tin,
Lead,
Nickel,
Silver,
Biſmuth,
Zinc,
Gold,
Platinum,
Mercury,
Arſenic,
Cobalt,
Sulphuret of arſenic,
Sulphur,
Phoſphorus?

Sect. XI. *Of Biſmuth.*

The ancients appear to have known nothing of biſmuth, nor do we know who diſcovered it; but it is firſt mentioned by George Agricola, who was born about the end of the 15th century.

148 Properties of biſmuth,

Biſmuth is of a yellowiſh or reddiſh white colour, and almoſt deſtitute both of taſte and ſmell.

It is brittle. Its hardneſs is 6*. Its ſpecific gravity is 9,8227‡. It melts at 460° Fahrenheit‡.

* Kirwan. † Briſſon. ‡ Lewis.

When heated in cloſe veſſels it ſublimes. When allowed to cool ſlowly after fuſion it cryſtallizes.

Biſmuth is not altered by water. When expoſed to the air it ſoon tarniſhes.

149 Its oxyds,

When biſmuth is kept fuſed in contact with air, it is gradually oxydated. When heated red hot, it emits a very faint blue flame, and its oxyd evaporates in the form of a yellowiſh ſmoke. When this ſmoke is collected, it is found to conſiſt of a brown coloured powder. This is the *brown oxyd of biſmuth*. It is compoſed of about 94 parts of biſmuth, and 6 of oxygen*. Biſmuth decompoſes nitric acid with great rapidity, by attracting its oxygen. If the quantity of acid be conſiderable, it diſſolves the oxyd as it forms; but the greater part of it may be precipitated by diluting the acid with water. This precipitate, which is a white powder, is *white oxyd of biſmuth*. It is compoſed of about 84 parts biſmuth, and 16 of oxygen†.

* Kirwan's Miner. ii. 489. † Ibid.

The affinities of the oxyds of biſmuth are, according to Bergman, as follows:

Oxalic acid,
Arſenic,
Tartarous,
Phoſphoric,
Sulphuric,
Sebacic,
Muriatic,
Benzoic(E)?
Nitric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Pruſſic,
Carbonic,
Ammonia.

150 Sulphuret,

Sulphur combines readily with biſmuth by fuſion. The ſulphuret of biſmuth is of a bluiſh grey colour, and cryſtallizes into beautiful tetrahedral needles. It is compoſed of 85 parts of biſmuth, and 15 of ſulphur‡.

‡ Wenzel, Kirwan's Miner. ii. 492.

151 Phoſphuret,

There appears to be little affinity between biſmuth and phoſphorus. Mr Pelletier attempted to produce the phoſphuret of biſmuth by various methods without ſucceſs. When he dropped phoſphorus, however, into biſmuth in fuſion, he obtained a ſubſtance which did not apparently differ from biſmuth, but which, when expoſed to the blow-pipe, gave evident ſigns of containing phoſphorus. Phoſphuret of biſmuth, according to Pelletier, is compoſed of about 96 parts of biſmuth, and four of phoſphorus*.

* Ann. de Chim. xiii. 130.

152 Alloys,

Biſmuth combines readily with moſt of the metals.

1. Equal parts of biſmuth and gold form a brittle alloy, nearly of the ſame colour with biſmuth†.

2. Equal parts of biſmuth and ſilver form alſo a brittle alloy, but leſs ſo than the laſt. The ſpecific gravity of both theſe is greater than intermediate‡.

† Keir, Macquer's Dict. ‡ Ibid.

3. The alloy of biſmuth and platinum is alſo very brittle. When expoſed to the air, it aſſumes a purple, violet, or blue colour. The biſmuth may be ſeparated by heat§.

§ Dr Lewis.

4. Mercury diſſolves biſmuth very eaſily. The amalgam is more fluid than pure mercury, and has the property of diſſolving lead and rendering it alſo fluid||. It is capable, however, of cryſtallizing. The cryſtals are either octahedrons, lamellated triangles, or hexagons. They are compoſed of one part of biſmuth and two of mercury¶.

|| Cramer. ¶ Chim. Dijon, i. 3.

5. The alloy of copper and biſmuth is not ſo red as copper.

6. Nothing is known concerning the alloy of iron and biſmuth.

7. Biſmuth and tin unite readily. A ſmall portion of biſmuth increaſes the brightneſs, hardneſs, and ſonorouſneſs of tin: It often therefore enters into the compoſition of the compound called *pewter*. Equal parts of tin and biſmuth form an alloy that melts at 280°: eight parts of tin, and one of biſmuth, melt at 390°: two parts of tin, and one of biſmuth, at 330°§.

§ Dr Lewis.

8. The alloy of lead and biſmuth is of a dark grey colour, a cloſe grain, but very brittle.

9. Biſmuth does not combine with zinc.

10. The alloy of antimony and biſmuth is unknown.

Biſmuth likewiſe enters into triple compounds with metals: Two parts of lead, three of tin, and five of biſmuth, form an alloy which melts at the heat of boiling water, which is 212°.

153 And affinities.

The affinities of biſmuth, according to Bergman, are as follows:

Lead,
Silver,
Gold,
Mercury,
Antimony,

(E) Muriatic acid decompoſes benzoat of biſmuth.—*Trommſdorf, Ann. de Chim.* xi. 317.

Antimony,
Tin,
Copper,
Platinum,
Nickel,
Iron,
Sulphuret of alkali,
Sulphur,
Phoſphorus ?

Sect. XII. *Of Arſenic.*

The word *arſenic* (αρσενικον) occurs firſt in the works of Dioſcorides, and of ſome other authors who wrote about the beginning of the Chriſtian era. It denotes in their works the ſame ſubſtance which Ariſtotle had called σανδαραχη (F), and his diſciple Theophraſtus αρρενικον, which is a reddiſh coloured mineral, compoſed of arſenic and ſulphur, uſed by the ancients in painting, and as a medicine.

The *white oxyd of arſenic*, or what is known in commerce by the name of arſenic, is mentioned by Avicenna in the 11th century ; but at what period the metal called arſenic was firſt extracted from that oxyd is unknown. Paracelſus ſeems to have known it. It is mentioned by Schroeder in his Pharmacopœia publiſhed in 1649*.

* *Bergman*, ii. 278.

154 Properties of Arſenic.

Arſenic when pure is of a bluiſh white colour. It is exceedingly brittle. Its hardneſs is 7†. Its ſpecific gravity 8,310.‡.

† *Kirwan's Miner.* ii. 254.

When expoſed to the temperature of 354° in cloſe veſſels it ſublimes§, and cryſtallizes in regular tetrahedrons.

‡ *Bergman*, ii. 278.
§ *Ibid.*

It is not much altered by water. Boiling water, however, is capable of diſſolving and retaining $\frac{1}{100000}$th of arſenic ; but that part of the metal is no doubt reduced to the ſtate of an oxyd‖.

155 Its oxyds,

‖ *Hahneman*, *Chim. Ann.* 1788, i. 182.

When arſenic is expoſed to the open air, it very ſoon loſes its luſtre, and is gradually converted into a greyiſh black ſubſtance by combining with oxygen. This is called the *grey oxyd of arſenic.*

When expoſed to a moderate heat in contact with air, it ſublimes in the form of a white powder, and at the ſame time emits a ſmell reſembling garlic. If the heat be increaſed, it burns with an obſcure bluiſh flame. This ſublimate is *white oxyd of arſenic*, which is compoſed of 93 parts of arſenic and 7 of oxygen¶.

¶ *Kirwan's Mineral.* ii. 490.

It is of a ſharp acrid taſte, which at laſt leaves an impreſſion of ſweetneſs, and is one of the moſt virulent poiſons known. It has an aliacious ſmell. It is ſoluble in 80 parts of water at the temperature of 60°, and in 15 parts of boiling water‡. When this ſolution is evaporated, the oxyd cryſtallizes.† When heated to 283°, it ſublimes : if heat be applied in cloſe veſſels, it becomes pellucid like glaſs, but when expoſed to the air, it ſoon recovers its former appearance. The ſpecific gravity of this glaſs is 5,000 ; that of the white oxyd, 3,706‡. This oxyd is capable of combining with moſt of the metals, and in general renders them brittle. Its affinities, according to Bergman, are as follows :

§ *Bergman*, ii. 278.
† *Brandt*, *Act. Upſal.* 1733.
‡ *Bergman*, ii. 278.

Muriatic acid,
Oxalic,
Sulphuric,
Nitric,
Sebacic,
Tartarous,
Phoſphoric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Arſenic,
Acetous,
Pruſſic,
Ammonia,
Water,
Alcohol ?

Arſenic, or rather the white oxyd of arſenic, is capable of combining with an additional doſe of oxygen. The compound produced is *arſenic acid*, firſt diſcovered by Scheele, which contains 91 parts of arſenic and 9 of oxygen*.

* *Berthollet*, *Kirwan's Miner.* ii. 490.

156 Sulphuret,

Arſenic combines readily with ſulphur. When heat is applied to a mixture of white oxyd of arſenic and ſulphur, the oxyd is decompoſed, part of the ſulphur combines with its oxygen, and the remainder unites with the reduced metal. The ſulphuret of arſenic produced by this proceſs is of a yellow colour, and was formerly called *orpiment*. It is compoſed, according to Weſtrum, of 20 parts of arſenic, and 80 of ſulphur†. It is often found native. If a ſtronger heat be applied, ſo as to melt the ſulphuret, it aſſumes a ſcarlet colour, and is much leſs volatile than formerly. This new compound was formerly called *realgar*. It is compoſed, according to Weſtrum, of 80 parts of arſenic, and 20 of ſulphur‡. The difference, therefore, between it and orpiment is evident. During the fuſion, part of the ſulphur without doubt ſublimes. It might be called *red ſulphuret of arſenic.*

† *Kirwan's Miner.* ii. 492.
‡ *Ibid.*

157 Phoſphuret,

Arſenic combines readily with phoſphorus. The phoſphuret of arſenic may be formed by diſtilling equal parts of its ingredients over a moderate fire. It is black and brilliant, and ought to be preſerved in water. It may be formed likewiſe by putting equal parts of phoſphorus and arſenic into a ſufficient quantity of water, and keeping the mixture moderately hot for ſome time§.

§ *Pelletier*, *Ann. de Chim.* xiii. 139.

Arſenic unites with moſt metals, and in general renders them more brittle and more fuſible.

158 Alloys.

1. Melted gold takes up $\frac{1}{60}$th of arſenic‖. The alloy is brittle and pale.

‖ *Bergman*, *ibid.*

2. Melted ſilver takes up $\frac{1}{14}$th of arſenic¶. The alloy is brittle.

¶ *Ibid.*

3. The alloy of platinum and arſenic is brittle and very fuſible. It was firſt formed by Scheffer. The arſenic may be ſeparated by heat.

4. The amalgam of arſenic is compoſed of five parts of mercury and one of arſenic§.

§ *Ibid.*

5. Copper

(F) Pliny ſeems to make a diſtinction between ſandaracha and arſenic. See Lib. xxxiv. c. 18.

Cobalt.

5. Copper takes up $\frac{5}{6}$ths of arsenic†. This alloy is white; and when the quantity of arsenic contained in it is small, both ductile and malleable†. It is called *white tombac*.

† *Ibid.*
† *Gellert.*

6. Iron is capable of combining with more than its own weight of arsenic§. This alloy is white, brittle, and capable of crystallizing. It is found native‖.

§ *Bergman, Ann. de Chim.* xiii. 139.
‖ *Kirwan's Miner.* ii. 256.

7. The alloy of tin and arsenic is harder and more sonorous than tin, and has much resemblance externally to zinc. Tin often contains a small quantity of arsenic.

8. Lead takes up $\frac{1}{6}$th of arsenic¶. The alloy is brittle and dark coloured.

¶ *Bergman, ibid.*

9. Zinc takes up $\frac{1}{5}$th of arsenic, antimony $\frac{1}{8}$th, and bismuth $\frac{1}{15}$th.*

* *Ibid.*

159 And affinities.

The affinities of arsenic, according to Bergman, are as follows:

Nickel,
Cobalt,
Copper,
Iron,
Silver,
Tin,
Gold,
Platinum,
Zinc,
Antimony,
Sulphuret of alkali,
Sulphur,
Phosphorus.

Sect. XIII. *Of Cobalt.*

A mineral called *cobalt* (G), of a grey colour, and very heavy, has been used in different parts of Europe since the 15th century to tinge glass of a blue colour. From this mineral Brandt obtained in 1733 a new metal, to which he gave the name of *cobalt*†.

† *Act. Upsal.* 1733.

160 Properties of cobalt,

Cobalt is of a white colour, inclining to a bluish or steel grey. When pure, it is somewhat malleable while red hot‡. Its hardness is 8§. Its specific gravity is 8,15 (H). It requires for fusion a heat at least as great as cast iron, which melts at 130° Wedgewood. No heat has been produced great enough to volatilize it‖.

‡ *Leonbardi.*
§ *Kirwan's Miner.* ii. 268.
‖ *Bergman,* iv.

Cobalt, when pure, does not seem to be affected by air or water.

It is attracted by the magnet.

Cobalt.

161 Its oxyds,

It is not oxydated by heat without very great difficulty; but it has the property of decomposing nitric acid, and of attracting oxygen by that means with great rapidity.

The *oxyd of cobalt* is of so deep a blue as to appear black. The oxyd procured by heat is composed of 88 parts of cobalt and 12 of oxygen; that by nitric acid contains about 77 parts of cobalt and 23 of oxygen.* Its affinities, according to Bergman, are as follows:

* *Kirwan's Miner.* ii. 268. 490.

Oxalic acid,
Muriatic,
Sulphuric,
Tartarous,
Nitric,
Sebacic,
Phosphoric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Arsenic,
Boracic,
Prussic,
Carbonic,
Ammonia.

162 Sulphuret,

The *sulphuret of cobalt* is not formed without difficulty. It is scarcely known.

163 Phosphuret,

Phosphuret of cobalt may be formed by heating the metal red hot, and then gradually dropping in small bits of phosphorus. It contains about $\frac{1}{15}$th of phosphorus. It is white and brittle, and when exposed to the air soon loses its metallic lustre. The phosphorus is separated by heat, and the cobalt is at the same time oxydated. This phosphuret is much more fusible than pure cobalt†.

† *Pelletier, Ann. de Chim.* xiii. 134.

164 Alloys,

The combinations of cobalt with other metals have been very little examined into.

1. The alloy of gold and cobalt is not known.

2. Cobalt does not combine with silver by fusion‡; but, according to Gellert, the alloy of silver and cobalt *may* be formed: it is brittle and of a grey colour§.

3. The alloy of platinum and cobalt is unknown.

4. Mer-

‡ *Bergman's Elect. Attract.*
§ *Metallur. Chim.*

(G) The word *cobalt* seems to be derived from *cobalus*, which was the name of a spirit that, according to the superstitious notions of the times, haunted mines, destroyed the labours of the miners, and often gave them a great deal of unnecessary trouble. The miners probably gave this name to the mineral out of joke, because it thwarted them as much as the supposed spirit, by exciting false hopes, and rendering their labour often fruitless; for as it was not known at first to what use the mineral could be applied, it was thrown aside as useless. It was once customary in Germany to introduce into the church-service a prayer that God would preserve miners and their works from *kobalts* and spirits. See *Beckmann's History of Inventions*, II. 362.

Mathesius, in his tenth sermon, where he speaks of *cadmia fossilis* (probably cobalt ore), says, " Ye miners call it *kobolt;* the Germans call the black devil and the old devil's whores and hags, old and black *kobel*, which by their witchcraft do injury to people and to their cattle."

Lehmann, Paw, Delaval, and several other philosophers, have supposed that *smalt* (oxyd of cobalt melted with glass and pounded) was known to the ancients, and used to tinge the beautiful blue glass still visible in some of their works; but we learn from Gmelin, who analysed some of these pieces of glass, that they owed their *blue* colour, not to the presence of *cobalt* but of *iron*.

According to Lehmann, cobalt ore was first used to tinge glass blue by Christopher Schurer, a glass-maker at Plattan, about the year 1540.

(H) *Berg.* II. 231. According to Brisson, 7,8119.

Nickel.

4. Mercury does not appear to amalgamate with cobalt.

5. The alloy of copper and cobalt is ſcarcely known.

6. The alloy of iron and cobalt is very hard, and not eaſily broken. Cobalt generally contains ſome iron, from which it is with great difficulty ſeparated.

7. The alloy of tin and cobalt is of a light violet colour.

8. Cobalt does not combine with lead by fuſion.

9. The alloy of zinc and cobalt is not formed without difficulty.

10. The alloy of antimony and cobalt is unknown.

11. Cobalt does not combine with biſmuth by fuſion.*

12. Arſenic combines very readily with cobalt. The alloy is brittle, much more fuſible, and more eaſily oxydated than pure cobalt†.

165 And affinities. The affinities of cobalt are as follows:

Iron,
Nickel,
Arſenic,
Copper,
Gold,
Platinum,
Tin,
Antimony,
Zinc,
Sulphuret of alkali,
Sulphur,
Phoſphorus?

† Bergman, iv.

Sect. XIV. *Of Nickel.*

A heavy mineral of a red colour is met with in ſeveral parts of Germany, which bears a ſtrong reſemblance to an ore of copper; but none of that metal can

166 Diſcovery of nickel. be extracted from it: for this reaſon the Germans called it *kupfer nickel* (devil's copper.) Hierne mentioned it in 1694. Cronſtedt was the firſt chemiſt who examined it with accuracy. He concluded from his experiments, which were publiſhed in the Stockholm Tranſactions for 1751 and 1754 that it contained a new metal, to which he gave the name of *nickel.*

Some chemiſts, particularly Mr Sage, affirmed, that it contained no new metal, but merely a compound of various known metals, which could be ſeparated from each other by the uſual proceſſes. Theſe aſſertions induced Bergman to undertake a very laborious courſe of experiments, in order if poſſible to obtain *nickel* in a ſtate of purity: for Cronſtedt had not been able to ſeparate a quantity of arſenic, cobalt, and iron, which adhered to it with much obſtinacy. Theſe experiments have been very fully detailed in the article Chemistry in the *Encycl.* to which we beg leave to refer. Bergman has ſhewn, that nickel poſſeſſes peculiar properties, and that it can neither be reduced to any other metal, nor formed artificially by any combination of metals. It muſt therefore be conſidered as a peculiar metal. It may poſſibly be a compound, and ſo may likewiſe many other metals; but we muſt admit every thing to be a peculiar body which has peculiar properties, and we muſt admit every body to be ſimple till ſome proof be actually produced that it is a compound; otherwiſe we forſake the road of ſcience, and get into the regions of fancy and romance.

Nickel is of a greyiſh white colour, and when leſs pure inclines a little to red.

It is both ductile and malleable. Its hardneſs is 8* 167 Its properties. Its ſpecific gravity 9,000†. It requires for fuſion a temperature at leaſt equal to 150° Wedgewood‡.

It is powerfully attracted by the magnet, and is even poſſeſſed of the property of attracting iron. This induced Bergman to ſuppoſe that nickel, when pureſt, was ſtill contaminated with about one-third of iron: but as this is the only proof of its containing iron, Klaproth, with reaſon, deems it an inſufficient one, and conſiders attraction by the magnet as a property of nickel§.

* Kirwan Miner. ii. 281.

† Bergman, ii. 231.

‡ Ibid.

§ Ann. de Chim. i. 170.

When expoſed to a ſtrong heat, nickel is oxydated ſlowly. Its oxyd is of a *brown* colour; if impure, it is *greeniſh*. The oxyd of nickel, according to Klaproth, is compoſed of 77 parts of nickel and 33 of oxygen¶. 168 Oxyds, Its affinities, according to Bergman, are as follows:

¶ Kirwan's Miner. ii. 490.

Oxalic acid,
Muriatic,
Sulphuric,
Tartarous,
Nitric,
Sebacic,
Phoſphoric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Arſenic,
Boracic,
Pruſſic,
Carbonic,
Ammonia,
Potaſs?
Soda?

Cronſtedt found that nickel combined readily with 169 Sulphuret, ſulphur by fuſion. The ſulphuret which he obtained was yellow and hard, with ſmall ſparkling facets; but the nickel which he employed was impure.

Nickel combines very readily with phoſphorus, either 170 Phoſphuret, by fuſing it along with phoſphoric glaſs, or by dropping phoſphorus into it while red hot. The phoſphuret of nickel is of a white colour, and when broke exhibits the appearance of very ſlender priſms collected together. When heated, the phoſphorus burns, and the metal is oxydated. It is compoſed of 83 parts of nickel and 17 of phoſphorus*. The nickel, however, on which this experiment was made, was not pure.

* Pelletier, Ann. de Chim. xiii. 135.

Little is known concerning the alloys of nickel with other metals. Equal parts of ſilver and nickel form a white ductile alloy. Equal parts of copper and nickel 171 Alloys, form a red ductile alloy. The compounds which this metal forms with tin and zinc are brittle. It does not combine with mercury†. It has a very ſtrong affinity for iron, cobalt, and arſenic, and is ſcarcely ever found except combined with ſome of them.

† Bergman. ii. 231.

Its affinities, according to Bergman, are as follows: 172 And affinities.

Iron,
Cobalt,
Arſenic,

Copper,

Manganese

Copper,
Gold,
Tin,
Antimony,
Platinum,
Bismuth,
Lead,
Silver,
Zinc,
Sulphuret of alkali,
Sulphur,
Phosphorus ?.

Sect. XV. *Of Manganese.*

[173] Discovery of manganese,

The dark grey mineral called *manganese*, in Latin *magnesia* (according to Boyle, from its resemblance to the *magnet)*, has been long known and used in making glass. A mine of it was discovered in England by Mr Boyle. It was long supposed to be an ore of iron; but Pott and Cronstedt having demonstrated that it contained very little of that metal, the latter referred it in his Mineralogy to a distinct order of earths, which he called *terra magnesiæ*. Bergman, from its specific gravity, and several other qualities, suspected that it was a metallic oxyd: he accordingly made several attempts to reduce it, but without success; the whole mass either assuming the form of scoriæ, or yielding only small separate globules attracted by the magnet. This difficulty of fusion led him to suspect that the metal he was in quest of bore a strong analogy to platinum. In the mean time, Dr Gahn, who was making experiments on the same mineral, actually succeeded in reducing it by the following process: He lined a crucible with charcoal powder moistened with water, put into it some of the mineral formed into a ball by means of oil, then filled up the crucible with charcoal powder, luted another crucible over it, and exposed the whole for about an hour to a very intense heat. At the bottom of the crucible was found a metallic button, or rather a number of small metallic globules, equal in weight to one-third of the mineral employed*. It is easy to see by what means this reduction was accomplished. The charcoal attracted the oxygen from the oxyd, and the metal remained behind. This metal is called *manganese*.

* Bergman, i. 211.

174 Its properties,

Manganese is of a greyish white colour. It is not malleable, and yet not so brittle as to be easily broken. Its hardness is 8†. Its specific gravity is 7,000‡. Its fusion requires so great a heat, that it has been very seldom accomplished.

† Kirwan's Miner. ii. 288.

‡ Hielm.

When reduced to powder, it is attracted by the magnet.

175 Oxyds,

When exposed to the air, it very soon tarnishes, and assumes a darker colour, till at last it becomes black and friable. This change is produced by the absorption of oxygen. It takes place much more rapidly if heat be applied to the metal. The substance thus obtained is the *black oxyd of manganese*. This oxyd is found in great abundance in nature, though scarcely ever in a state of purity. It is composed of 75 parts of manganese, and 25 of oxygen*.

* Bergman, ii. 225.

If a quantity of muriatic acid be poured upon this oxyd, and heat applied, part of the acid combines with some of the oxygen of the oxyd, and flies off in yellow fumes. The oxyd is dissolved in the rest. If potass be added to this solution, a white powder is precipitated. This is the *white oxyd of manganese*. It contains, according to Bergman, about 80 parts of manganese and 20 of oxygen. It soon attracts more oxygen when exposed to the air, and is converted into *black oxyd*.

The affinities of the white oxyd, according to Bergman, are as follows:

Oxalic acid,
Citric,
Phosphoric,
Tartarous,
Fluoric,
Muriatic,
Sulphuric,
Nitric,
Saccholactic,
Succinic,
Sebacic,
Tartaric,
Formic,
Lactic,
Acetous,
Prussic,
Carbonic.

The sulphuret of manganese is unknown. 176

Phosphuret,

Phosphorus may be combined with manganese by melting together equal parts of the metal and of phosphoric glass; or by dropping phosphorus upon red hot manganese. The phosphuret of manganese is of a white colour, brittle, granulated, disposed to crystallize, not altered by exposure to the air, and more fusible than manganese. When heated the phosphorus burns and the metal becomes oxydated†.

† Pelletier, Ann. de Chim. xiii. 137.

177 Carburet,

Manganese combines readily with carbon by fusion(1).

178 Alloys,

Little is known concerning the alloys of manganese. It combines readily with copper. The compound, according to Bergman, is very malleable, its colour is red, and it sometimes becomes green by age. Gmelin made a number of experiments to see whether this alloy could be formed by fusing the black oxyd of manganese along with copper. He partly succeeded, and proposed to substitute this alloy instead of the alloy of copper and arsenic, which is used in the arts‡. We believe, however, that upon trial, the new alloy has been found not to answer.

‡ Ann. de Chim. i. 303.

Manganese combines readily with iron; indeed it has scarcely ever been found quite free from some mixture of that metal. It combines also very easily with arsenic and tin, not easily with zinc, and not at all with mercury§.

§ Bergman, ii. 211.

179 And affinities.

The affinities of manganese, according to Bergman, are as follows:

Copper,
Iron,
Gold,
Silver,

(1) *Bergman*, III. 379.—Sometimes manganese is very speedily oxydated by exposure to the air; sometimes scarcely altered by it, as Klaproth and Pelletier have observed. Mr Kirwan supposes, that the manganese which is soon altered contains carbon, and that this is the cause of the difference. See *Miner*. II. 288.

Tungſten.

Silver,
Tin,
Sulphuret of alkali,
Phoſphorus ?
Carbon ?

The three metals, *cobalt*, *nickel*, and *mangan eſe*, reſemble iron in ſeveral particulars: Like it they are magnetic, very hard, and very difficult to fuſe: but they differ from it in ſpecific gravity, malleability, and in the properties of all their combinations with other ſubſtances; the oxyds, for inſtance of iron, cobalt, nickel, and manganeſe, poſſeſs very different qualities.

Sect. XVI. *Of Tungſten.*

180 Diſcovery of tungſten,

There is a mineral found in Sweden of an opaque white colour, and great weight; from which laſt circumſtance it got the name of *tungſten*, or *ponderous ſtone*. Some mineralogiſts conſidered it as an ore of tin, others ſuppoſed that it contained iron. Scheele analyſed it in 1781, and found that it was compoſed of lime and a peculiar earthy-like ſubſtance, which he called from its properties *tungſtic acid*. Bergman conjectured that the baſis of this acid was a metal; and this conjecture was ſoon after fully confirmed by the experiments of Meſſrs D'Elhuyart, who obtained the ſame ſubſtance from a mineral of a browniſh black colour, called by the Germans *wolfram*, which is ſometimes found in tin mines. This mineral they found to contain $\frac{65}{100}$ of tungſtic acid; the reſt of it conſiſted of manganeſe, iron and tin. This acid ſubſtance they mixed with charcoal powder, and heated violently in a crucible On opening the crucible after it had cooled, they found in it a button of metal of a dark brown colour, which crumbled to powder between the fingers. On viewing it with a glaſs, they found it to conſiſt of a congeries of metallic globules, ſome of which were as large as a pin head. The metal thus obtained is called *tungſten*. The manner in which it was produced is evident; tungſtic acid is compoſed of oxygen and tungſten: the oxygen combined with the carbon, and left the metal in a ſtate of purity.

181 Its properties.

Tungſten is externally of a brown colour, internally of a ſteel grey*.

Its ſpecific gravity is 17,600‡. It is more infuſible than manganeſe‖.

When heat is applied to tungſten it is converted into a yellow powder, compoſed of 80 parts of tungſten and 20 of oxygen†. This is the *yellow oxyd of tungſten* or *tungſtic acid*.

The ſulphuret of tungſten is of a bluiſh black colour, hard, and capable of cryſtallizing.

Phoſphorus is capable of combining with tungſten§.

Of the alloys of tungſten we know nothing, except from the experiments of Elhuyarts, which have been tranſcribed into the article chemiſtry in the *Encyclopædia*; to which, therefore, we beg leave to refer.

‡ *Id.*
‖ *Id.*
† *Id.*
§ *Pelletier, Ann. de Chim.* xiii. 137.

Sect. XVII. *Of Molybdenum.*

182 Diſcovery of molybdenum.

The Greek word *molybdena*, and its Latin tranſlation *plumbago*, ſeem to have been employed by the ancients to denote various oxyds of lead; but by the moderns they were applied indiſcriminately to all ſubſtances poſſeſſed of the following properties: Light, friable, and ſoft, of a dark colour and greaſy feel, and which leave a ſtain upon the fingers. Scheele firſt examined theſe minerals with attention. He found, that two very different ſubſtances had been confounded together. To one of theſe, which is compoſed of carbon and iron, and which has been already deſcribed, he appropriated the word *plumbago*; the other he called *molybdena*.

Molybdenum.

Molybdena is compoſed of ſcaly particles adhering ſlightly to each other. Its colour is bluiſh, very much reſembling that of lead. Scheele analyſed it, and obtained ſulphur and a whitiſh powder, which poſſeſſed the properties of an acid, and which, therefore, he called *acid of molybdena*. Bergman firſt ſuſpected that the baſis of this acid was a metal. It was at the requeſt of Bergman and Scheele that Mr Hielm began the laborious courſe of experiments by which he ſucceeded in obtaining a metal from this acid. His method was to form it into a paſte with linſeed oil, and then to apply a very ſtrong heat. This proceſs he repeated ſeveral times ſucceſſively. Klaproth and Pelletier alſo attempted to reduce it, and with equal ſucceſs. The metal is *molybdenum* (K).

183 Its properties.

Molybdenum is externally of a whitiſh yellow colour, but its fracture is a whitiſh grey.

Hitherto it has only been procured in ſmall grains, agglutinated together in brittle maſſes.

Its ſpecific gravity is 7,500. It is almoſt infuſible in our fires.

When expoſed to a ſtrong heat, it is gradually converted into a whitiſh-coloured oxyd‡. When nitric acid is poured upon it, molybdenum attracts oxygen, and is converted into a *white oxyd*, which poſſeſſes the properties of an acid†. This is the *molybdic acid*.

Molybdenum combines readily with ſulphur; and the compound has exactly the properties of molybdena, the ſubſtance which Scheele decompounded§. Molybdena is therefore *ſulphuret of molybdenum*. The reaſon that Scheele obtained from it molybdic acid was, that the metal combined with oxygen during his proceſs.

Molybdenum is alſo capable of combining with phoſphorus*.

Few of the alloys of this metal have been hitherto examined.

It ſeems capable of uniting with gold. The alloy is probably of a white colour‡.

It combines readily with platinum while in the ſtate of an oxyd. The compound is fuſible. Its ſpecific gravity is 20,00§.

The alloys of molybdenum with ſilver, iron and copper, are metallic and friable; thoſe with lead and tin are powders which cannot be fuſed*.

Sect. XVIII. *Of Uranium.*

184 Diſcovery of uranium.

There is a mineral found in the George Wagsfort mine at Johann-Georgenſtadt in Saxony, partly in a pure or unmixed ſtate, and partly ſtratified with other kinds of ſtones and earths. The firſt variety is of a blackiſh colour inclining to a dark iron grey, of a moderate ſplendor, a cloſe texture, and when broken preſent a ſomewhat uneven, and, in the ſmalleſt particles, a conchoidal ſurface. It is quite opaque, tolerably hard, and on being pounded yields a black powder. Its ſpecific gravity is about 7,500. The ſecond ſort is diſtinguiſhed

(K) This name was given it by Hielm.

Uranium. diſtinguiſhed by a finer black colour, with here and there a reddiſh caſt; by a ſtronger luſtre, not unlike that of pitcoal; by an inferior hardneſs; and by a ſhade of green, which tinges its black colour when it is reduced to powder.*

* Klaproth, Crell's Journal, Eng. tranſl. i. 126.

This foſſile was called *pechblende;* and mineralogiſts, miſled by the name (L), had taken it for an ore of zinc, till the celebrated Werner, convinced from its texture, hardneſs, and ſpecific gravity, that it was not a *blende*, placed it among the ores of iron. Afterwards he ſuſpected that it contained *tungſten;* and this conjecture was ſeemingly confirmed by the experiments of ſome German mineralogiſts, publiſhed in the Miners Journal ‡. But Klaproth, whoſe analyſes always diſplay the moſt conſummate ſkill, joined with the moſt rigid accuracy, examined this mineral about the year 1789, and found that it conſiſted chiefly of ſulphur combined with a peculiar metal, to which he gave the name of *uranium* (M).

‡ Ibid.

185 Its properties. Uranium is of a dark grey colour; internally it is ſomewhat inclined to brown ‡.

‡ Ibid. 233.

Its malleability is unknown. Its hardneſs is about 6. It requires a ſtronger heat for fuſion than manganeſe. Indeed Klaproth only obtained it in very ſmall conglutinated metallic grains, forming altogether a porous and ſpongy maſs.—Its ſpecific gravity is 6,440 ‖.

‖ Ibid.

When expoſed for ſome time to a red heat, it ſuffers no change. By means of nitric acid, however, it may be converted into a yellow powder. This is the *yellow oxyd of uranium.* This oxyd is found native mixed with the mineral above deſcribed. Its affinities have not yet been determined.

Uranium is capable of combining with ſulphur. The mineral from which Mr Klaproth firſt obtained it is a native ſulphuret of uranium.

Nothing is known concerning the alloys or affinities of uranium.

SECT. XIX. *Of Titanium.*

186 Diſcovery of titanium. THERE is a mineral found in Hungary which, from its external appearance, has been called *red ſhorl;* but Klaproth, who examined it about the year 1795, diſcovered that it conſiſted chiefly of a peculiar metal, to which he gave the name of *titanium.*

187 Its properties. Titanium is of a browniſh red colour, and conſiderable luſtre. It is brittle. Its hardneſs is 9; its ſpecific gravity 4,18.

When expoſed to a ſtrong heat in a clay crucible, it ſuffered no alteration, except that its colour became browner; but in a coal crucible it loſt its luſtre and broke to pieces.

It is found naturally cryſtallized in right-angled quadrangular priſms, longitudinally furrowed, and about ½ inch in length.

No acid had any effect in oxydating it; but when mixed with five times its weight of potaſs, and heated in a porcelain furnace, it melted, and formed when cold a denſe greyiſh maſs, the ſurface of which was cryſtallized. When diſſolved in boiling water, it ſoon let fall a white powder, weighing about one-third more than the titanium employed. This is the *oxyd of titanium.* Fifty grains of it were reduced by ignition to 38. While hot it was yellowiſh, but, like oxyd of zinc, became white as it cooled. When heated on charcoal, it aſſumes firſt a *roſy red*, and afterwards a *ſlate blue* colour, and at laſt melts into an imperfect bead with a finely ſtriated ſurface. Mr Klaproth did not ſucceed in reducing it to the metallic ſtate.

Titanium does not ſeem to have any affinity for ſulphur †.

† M'Gregor.

188 There was a ſubſtance diſcovered by Mr M'Gregor in the valley of Menachan in Cornwall, and hence called *menachanite.* Upon this ſubſtance Mr M'Gregor made a very intereſting ſet of experiments, which were publiſhed in the Journal de Phyſique for 1791. He ſuſpected it to contain a new metal. From its properties, Mr Kirwan conjectured that it was the ſame with titanium;* and this conjecture has been very lately confirmed by Mr Klaproth, who analyſed menachanite, and found it to be an ore of that metal. Menachanite.

* Mineral. ii. 331.

SECT. XX. *Of Tellurium.*

189 Diſcovery of tellurium. IN the mountains of Fatzbay, near Zalethna in Tranſylvania, there is a mine called *Mariahilf;* the ore of which is wrought for the gold that it contains. Mr Muller of Reichenſtein examined it in 1782, and ſuſpected that it contained a new metal; and Bergman, to whom he had ſent ſome of the ore, was of the ſame opinion: but the quantity of the mineral which theſe chemiſts had examined was too inconſiderable to enable them to decide with certainty. Klaproth analyſed a larger quantity of it about the year 1797, and found that 1000 parts of it conſiſted of 72 parts of iron, 2,5 of gold, and 925,5 of a new metal, to which he has given the name of *tellurium* (N).

190 Its properties. Tellurium is of a white colour like tin, approaching ſomewhat to the grey colour of lead.*

* Klaproth, Philoſophical Magazine, i. 78.

It is very brittle and friable. Its fracture is laminated. Its ſpecific gravity is 6,115.

It is as eaſily melted as lead. When ſuffered to cool quietly and gradually, it readily aſſumes a cryſtallized ſurface †.

† Muller.

When heated by the blowpipe upon charcoal, it burns with a very lively flame of a blue colour, inclining at the edges to green. It is ſo volatile as to riſe entirely in a whitiſh grey ſmoke; at the ſame time it exhales a diſagreeable odour like that of radiſhes. This ſmoke is the *white oxyd* of tellurium, which may be formed alſo by diſſolving the metal in nitro-muriatic acid, and pouring into the ſaturated ſolution a quantity of water: a white powder precipitates, which is the oxyd ‡.

‡ Klaproth.

When this oxyd is heated for ſome time in a retort, it melts, and appears, after cooling, of a yellow ſtraw colour, having acquired a ſort of radiated texture. When formed

(L) *Blende* is the name given to ores of zinc.

(M) From *Uranus* (Οὐρανος), the name given by Mr Bode to the new planet diſcovered by Herſchel; which name the German aſtronomers have adopted. Mr Klaproth called the metal at firſt *uranite;* but he afterwards changed that name for *uranium.*

(N) Mr Kirwan, in the new edition of his Mineralogy, which was publiſhed before Mr Klaproth's experiments were known, gives this metal the name of *Sylvanite.*—Tellurium exiſts in ſeveral other mines in the ſame mountains.

Tellurium. formed into a paste with any fat oil, and distilled in a red heat, brilliant metallic drops are observed to cover the upper part of the retort, which at intervals fall to the bottom of the vessel, and are immediately replaced by others. After cooling, metallic fixed drops are found adhering to the sides and at the bottom of the vessel; the remainder of the metal is reduced. Its surface is brilliant and almost always crystallized. When this oxyd is exposed to heat on charcoal, it is reduced with a rapidity that resembles detonation.*

* Klaproth.

Tellurium combines with sulphur. The sulphuret of this metal is of a grey colour and radiated structure. When placed on red hot charcoal, the metal burns as well as the sulphur with a blue flame.

Tellurium amalgamates with mercury by simple trituration§.—The other properties of this metal are unknown.

§ Muller.

191 Chromum. A new metal has lately been discovered by Vauquelin in the red lead ore of Siberia. It is grey, very hard, brittle, and easily crystallizes in small needles†. He has given it the name of *chromum* (o).

† Nicholson's Journal, ii. 146.

We have now described all the metals at present known. The following table will exhibit in one view their principal properties.

192 General table of the properties of the metals.

We

Tellurium.

193 Remarks on metallic oxyds.

We have feen that all the metals are capable of combining with oxygen; that almoft every one forms various oxyds, containing different quantities of oxygen, and varying in colour and other properties according to the proportion of oxygen which they contain. No part of chemiftry has more engaged the attention of philofophers than the metallic oxyds; and yet fuch is the difficulty of the fubject, that fcarcely any part of chemiftry is more imperfectly underftood.

We neither know how many oxyds every particular metal is capable of forming, nor the manner in which they are formed: neither have the differences between oxyds of the fame metallic bafe been enquired into; though there cannot be a doubt that they differ, not only in their affinities, but in many of their other properties. The *white oxyd* of manganefe, for inftance, combines readily with acids, but the *black* is incapable of uniting with any.

Mr Prouft, in a very valuable paper which he lately publifhed concerning the oxyds of iron*, hints that metals are only capable of two degrees of oxydation, or, which is the fame thing, that only two different oxyds can be produced from the fame metal. We think he has proved this completely as far as iron is concerned; and probably the obfervation holds good with refpect to many other metals. Arfenic, copper, tin, molybdenum, and perhaps even mercury, feem to be capable of only two degrees of oxydation; but it would require a very numerous and accurate fet of experiments to be able to determine the matter, or even to form a probable conjecture. Analogy is certainly againft the fuppofition; for it has been demonftrated that fome fubftances at leaft are capable of combining with three different dofes of oxygen (q), and why may not this be the cafe alfo with the metals? (11).

* *Ann. de Chim.* xxiii. 85.—*Nicholfon's Journ.* i. 453.

There is one obfervation, however, which we owe to Mr Prouft, the truth of which cannot be doubted, and which is certainly of the higheft importance—that metals are not capable of indefinite degrees of oxydation, but only of a certain number; and that every particular oxyd confifts of a determinate quantity of the metal and of oxygen chemically combined. Iron, for inftance, is not capable, as has been fuppofed, of uniting with oxygen in all the intermediate degrees between $\frac{27}{100}$ and $\frac{48}{100}$, and confequently of forming 20 or 30 different oxyds; it can only combine with precifely $\frac{27}{100}$ parts, or $\frac{48}{100}$ parts, and with no other proportions; and therefore is only capable of forming two oxyds, the *green* and the *brown*. In like manner, every other metal combines with certain proportions of oxygen, and forms either two oxyds or more according to its nature. To talk therefore of oxydating a metal indefinitely is not accurate, except it be intended to fignify the combining of part of it with oxygen, while the reft remains in its natural ftate. If iron be oxydated at all, it muft be combined with $\frac{27}{100}$ of oxygen; if it be oxydated more than this, it muft be combined with $\frac{48}{100}$ of oxygen.

Tellurium.

We beg leave to add another obfervation, which we confider as of no lefs importance, and which will ferve in fome meafure to modify and explain what has been juft now faid. Oxygen is capable of uniting with metals, or with any other fubftance for which it has an affinity, only in *one* determinate proportion. Iron, for inftance, and oxygen can only combine in the proportion of 73 parts of iron and 27 of oxygen. Thefe two quantities faturate each other, and form a compound which is incapable of receiving into it any more oxygen or iron: this compound is the *green oxyd of iron.* How comes it then, it will be afked, that there is another oxyd of iron, the *brown oxyd*, which contains 52 parts of iron and 48 of oxygen, proportions certainly very different from 73 and 27? We anfwer, there is an affinity between the green oxyd of iron and oxygen; they are capable of combining together, and of faturating each other in the proportion of about 71,5 parts of green oxyd and 28,5 of oxygen; and the compound which they form is the *brown oxyd*, which of courfe contains 52 parts of iron and 48 of oxygen: But then it is not formed by the combination of thefe two fubftances directly, but by the combination of the green oxyd and oxygen. In like manner, the arfenic acid is not compofed of arfenic and oxygen combined directly, but of white oxyd of arfenic combined with oxygen. The very fame thing takes place in all the other metals. We cannot at prefent prove the truth of this obfervation in a fatisfactory manner, becaufe it would be neceffary to draw our proofs from combinations which are yet undefcribed; but we will have occafion to confider it afterwards (12).

We have feen, that all the metals hitherto tried are capable of combining with fulphur, except gold and titanium; that all of them on which the experiments have been made can be united with phofphorus; and that three of them, iron, zinc, and manganefe, united with carbon; and perhaps many more of them may hereafter be found capable of affuming the form of carburets.

We have feen, too, that they are capable of uniting with one another and forming alloys. This was long reckoned peculiar to metals, and it is at prefent one of the beft criterions for determining the metallic nature of any fubftance. Much is wanting to render the chemiftry of alloys complete. Many of them have never been examined; and the proportions of almoft all of them are unknown. Neither has any accurate method been yet difcovered of determining the affinities of metals for each other. The order of affinities which we have given for each metal was determined by Bergman; but he acknowledged himfelf that he wanted the proper data to enfure accuracy.

CHAP.

(q) We fhall fee afterwards that azot is one of thefe.

(11) When we oxyd any metal in a *low* temperature, it goes regularly on, combining with frefh portions of oxygen until it is faturated. How can we make this fact accord with the theory of each of the metals being capable of exifting in but two degrees of oxydation? Will it be fufficient to fay that the frefh portions of oxygen unite to frefh portions of the metal? Or would this account for the various colours fome metals affume in the courfe of oxydation? T. P. S.

(12) As this fanciful theory is founded on deductions from "combinations which are yet undefcribed," we fhall wait till we meet with them before we enter on its examination. T. P. S.

Chap. IV. *Of* Earths.

The word *earth*, in common language, has two meanings; it ſometimes ſignifies the *globe* which we inhabit, and ſometimes the *mould* on which vegetables grow. Chemiſts have examined this mould, and have found that it conſiſts of a variety of ſubſtances mixed together without order or regularity. The greateſt part of it, however, as well as of the ſtones, which form apparently ſo large a proportion of the globe, conſiſts of a ſmall number of bodies, which have a variety of common properties. Theſe bodies chemiſts have agreed to claſs together, and to denominate *earths*.

194 Properties of earths.

Every body which poſſeſſes the following properties is an *earth*:

1. Inſoluble in water, or nearly ſo; or at leaſt becoming inſoluble when combined with carbonic acid.

2. Little or no taſte or ſmell; at leaſt when combined with carbonic acid.

3. Incombuſtible, and incapable while pure of being altered by the fire.

4. A ſpecific gravity not exceeding 4,9.

5. When pure, capable of aſſuming the form of a white powder.

The earths at preſent known amount to eight; the names of which are, lime, magneſia, barytes, ſtrontites, alumina, ſilica, jargonia, glucina.

Every one of the above characteriſtics is not perhaps rigorouſly applicable to each of theſe bodies; but all of them poſſeſs a ſufficient number of common properties to render it uſeful to arrange them under one claſs.

Sect. I. *Of Lime.*

Lime has been known from the earlieſt ages. The ancients employed it in medicine: it was the chief ingredient in their mortar; and they uſed it as a manure to fertilize their fields.

195 Method of procuring lime.

It abounds in many parts of the world, or perhaps we ſhould rather ſay, that there is no part of the world where it does not exiſt. It is found pureſt in limeſtones, and marbles and chalk. None of theſe ſubſtances, however, is, ſtrictly ſpeaking, lime; but they are all capable of becoming lime by a well-known proceſs, by keeping them for ſome time in a white heat: this proceſs is called *the burning of lime;* the product is denominated *quicklime*. This laſt ſubſtance is what we call *lime*.

196 Properties of lime.

Pure lime is of a white colour, moderately hard, but eaſily reduced to a powder.

It has a hot burning taſte, and in ſome meaſure corrodes and deſtroys the texture of thoſe animal bodies to which it is applied. It has no ſmell. Its ſpecific gravity is 2,3*.

If water be poured on newly burnt lime, it ſwells and falls to pieces, and is ſoon reduced to a very fine powder. In the mean time, ſo much heat is produced, that part of the water flies off in vapour. If the quantity of lime ſlacked (as this proceſs is termed) be great, the heat produced is ſufficient to ſet fire to combuſtibles. In this manner, veſſels loaded with lime have ſometimes been burnt. When great quantities of lime are ſlacked in a dark place, not only heat, but light alſo is emitted, as Mr Pelletier has obſerved §. When ſlacked lime is weighed, it is found to be heavier than it was before. This additional weight is owing to the combination of part of the water with the lime; which water may be ſeparated again by the application of a red heat; and by this proceſs the lime becomes juſt what it was before being ſlacked ||.

* *Kirwan's Miner.* i. 5.

§ *Jour. de Phyſ.* t. 22.

|| *Dr Black.*

197 Lime-water.

Six hundred parts of water, at the temperature of 60°, diſſolve about one part of lime; boiling hot water diſſolves about double that quantity*. This ſolution is called *lime-water*. It is limpid, has an acrid taſte, and changes vegetable blue colours to green. One ounce troy of lime-water contains about one grain of lime.

* *Kirwan's Miner.* i. 5.

One thouſand parts of lime are capable of abſorbing, and retaining, at a heat of 600°, 228 parts of water §.

§ *Lavoiſier.*

Lime has never yet been obtained in the ſtate of cryſtals.

It is incapable of being fuſed by the moſt violent heat that can be produced in furnaces, or even by the moſt powerful burning glaſſes.

198 Sulphuret, and

Lime unites readily with ſulphur, and forms *ſulphuret of lime*. This compound may be obtained by mixing unſlacked lime and flowers of ſulphur together, and adding a little water. The heat produced by the ſlacking of the lime is ſufficient to make the ſulphur and the lime unite. This ſulphuret is of a red colour. When water is poured on it, ſulphurated hydrogen gas is emitted. The ſulphur is gradually converted into ſulphuric acid by uniting with the oxygen of the water, the hydrogen of which flies off in the form of gas, diſſolving at the ſame time a part of the ſulphur.

199 Phoſphuret of lime.

It is capable alſo of combining with phoſphorus.—The phoſphuret of lime decompoſes water by the aſſiſtance of a moderate heat, and gives out phoſphurated hydrogen gas.

200 Cauſe of the difference between limeſtone and lime,

Limeſtone and chalk, though they are capable of being converted into lime by *burning*, poſſeſs hardly any of the properties of that active ſubſtance. They are taſteleſs, ſcarcely ſoluble in water, and do not perceptibly act on animal bodies. Now, to what are the new properties of lime owing? What alteration does it undergo in the fire?

It had been long known, that limeſtone loſes a good deal of weight by being burned or *calcined*. It was natural to ſuppoſe, therefore, that ſomething was ſeparated from it during calcination. Accordingly, Van Helmont, Ludovicus, and Macquer, made experiments in ſucceſſion, in order to diſcover what that *ſomething* was; and they concluded from them that it was *pure water*, which the lime recovered again when expoſed to the atmoſphere. As the new properties of lime could hardly be aſcribed to this loſs, but to ſome other cauſe, Stahl's opinion, like all the other chemical theories of that wonderful man, was generally acceded to. He ſuppoſed that the new properties, which lime acquired by calcination, were owing entirely to the more minute diviſion of its particles by the action of the fire. Boyle indeed had endeavoured to prove, that theſe properties were owing to the *fixation of fire* in the lime; a theory which was embraced by Newton and illuſtrated by Hales, and which Meyer new modelled, and explained with ſo much ingenuity and acuteneſs as to draw the attention of the moſt diſtinguiſhed chemiſts. But while Meyer was thus employed in Germany, Dr Black of Edinburg publiſhed thoſe celebrated experiments which form ſo brilliant an era in the hiſtory of chemiſtry.

201 According to Stahl;

202 Explained by Dr Black

He firſt aſcertained that the quantity of water ſeparated from limeſtone during its calcination was not near-

Lime. ly equal to the weight which it loſt. He concluded in conſequence, that it muſt have loſt ſomething elſe than mere water. What this could be, he was at firſt at a loſs to conceive; but recollecting that Dr Hales had proved, that limeſtone, during its ſolution in acids, emitted a great quantity of *air*, he conjectured that *this* might probably be what it loſt during calcination. He calcined it accordingly, and applied a pneumatic apparatus to receive the product. He found his conjecture verified; and that the *air* and *the water* which ſeparated from the lime, were together preciſely equal to the loſs of weight which it had ſuſtained. Lime therefore owes its new properties to the loſs of *air*; and limeſtone differs from lime merely in being combined with a certain quantity of *air*: for he found that, by reſtoring again the ſame quantity of *air* to lime, it was converted into limeſtone. This air, becauſe it exiſted in lime in a fixed ſtate, he called *fixed air*. It was afterwards examined by Dr Prieſtley and other philoſophers, found to poſſeſs peculiar properties, and to be that ſpecies of gas now known by the name of *carbonic acid gas*. Lime then is a ſimple ſubſtance, that is to ſay, it has never yet been decompounded; and limeſtone is compoſed of carbonic acid and lime. Heat ſeparates the carbonic acid, and leaves the lime in a ſtate of purity.

203 Affinities of lime. The affinities of lime, according to Bergman, are as follows:

Oxalic acid,
Suberic (R)?
Sulphuric,
Tartarous,
Succinic,
Phoſphoric,
Saccholactic,
Nitric,
Muriatic,
Sebacic,
Fluoric,
Arſenic,
Formic,
Lactic,
Citric,
Benzoic,
Sulphurous,
Acetous,
Boracic,
Nitrous,
Carbonic,
Pruſſic,
Sulphur,
Phoſphorus,
Water,
Fixed oil.

Sect. II. *Of Magneſia.*

204 Diſcovery of magneſia. About the beginning of the eighteenth century, a Roman canon expoſed a white powder to ſale at Rome as a cure for all diſeaſes. This powder he called *magneſia alba*. He kept the manner of preparing it a profound ſecret; but in 1707 Valentini informed the public that it might be obtained by calcining the lixivium which remains after the preparation of nitre; and two years after, Slevogt diſcovered that it might be precipitated by potaſs from the mother ley (s) of common ſalt. This powder was generally ſuppoſed to be *lime*, till Frederic Hoffman obſerved that it formed very different combinations with other bodies.* But little was known concerning its nature till Dr Black publiſhed his celebrated experiments in 1755. Margraf publiſhed a diſſertation on it in 1759, and Bergman another in 1775, in which he collected the obſervations of theſe two philoſophers, and which he enriched alſo with many additions of his own.

* Bergman, i. 365.

205 Method of procuring it. As magneſia has never yet been found native in a ſtate of purity, it may be prepared in the following manner: *Sulphat of magneſia*, a ſalt compoſed of this earth and ſulphuric acid, exiſts in ſea water, and in many ſprings, particularly ſome about Epſom, from which circumſtance it was formerly called *Epſom ſalt*. This ſalt is to be diſſolved in water, and half its weight of potaſs added. The magneſia is immediately precipitated, becauſe potaſs has a ſtronger affinity for ſulphuric acid. It is then to be waſhed with a ſufficient quantity of water, and dried.

206 Its properties. Magneſia thus obtained is a very ſoft white powder, which has very little taſte, and is totally deſtitute of ſmell.—Its ſpecific gravity is about 2,3 §.

It is ſoluble in about 7900 times its own weight of water at the temperature of 60° ‖.

§ *Kirwan's Miner.* i. 8.

‖ *Ibid.*

Even when combined with carbonic acid (for which it has a ſtrong affinity) it is capable of abſorbing and retaining 1½ times its own weight of water, without letting go a drop; but on expoſure to the air, this water evaporates, though more ſlowly than it would from lime.

Magneſia has never yet been obtained in a cryſtallized form.

It tinges vegetable blues of an exceedingly ſlight green.

It is not melted by the ſtrongeſt heat which it has been poſſible to apply; but Mr D'Arcet obſerved that, in a very high temperature, it became ſomewhat agglutinated.

When magneſia and ſulphur are put into a veſſel of water, and kept for ſome time expoſed to a moderate heat, they combine, and form ſulphuret of magneſia; which, according to Fourcroy, is capable of cryſtallizing.

The phoſphuret of magneſia has never been examined.

207 Effect of heat on mixtures of lime and magneſia. Equal parts of lime and magneſia mixed together, and expoſed by Lavoiſier to a very violent heat, did not melt; neither did they melt when Mr Kirwan placed them in the temperature of 150° Wedgewood.—The following

(R) The affinity of this acid for lime is inferior to the oxalic, which decompoſes the ſuberat of lime. *Jameſon's Mineral. of Shetland and Arran*, p. 168.

(s) *The mother ley* is the liquid that remains after as much as poſſible of any ſalt has been obtained from it. Common ſalt, for inſtance, is obtained by evaporating ſea water. After as much ſalt has been extracted from a quantity of ſea water as will cryſtallize, there is ſtill a portion of liquid remaining. This portion is the mother ley.

Magnefia. following table, drawn up by Mr Kirwan from his own experiments, fhews the effect of heat on thefe two earths mixed together in different proportions,

Proportions.	Heat.	Effect.
80 Lime 20 Mag.	150° Wedg.	Went through the crucible.
75 Lime 25 Mag.	160	Went through the crucible.
66 Lime 33 Mag.		Went through the crucible.
20 Lime 80 Mag.	165	Did not melt.
33 Lime 66 Mag.	138	Did not melt.
30 Lime 10 Mag.	156	Melted into a fine greenifh yellow glafs; but the crucible was corroded throughout.

208 Affinities of magnefia. The affinities of magnefia, according to Bergman, are as follows:

Oxalic acid,
Phofphoric,
Sulphuric,
Fluoric,
Sebacic,
Arfenic,
Saccholactic,
Succinic,
Nitric,
Muriatic,
Tartarous,
Citric,
Formic,
Lactic,
Benzoic,
Acetous,
Boracic,
Sulphurous,
Nitrous,
Carbonic,
Pruffic,
Sulphur,
Phofphorus?
Water.

Sect. III. *Of Barytes.*

209 Difcovery of barytes. A very heavy mineral is found in Sweden, Germany, and Britain, which Margraf confidered as a compound of fulphuric acid and lime. But Scheele and Gahn analyfed it in 1774, and found that it confifted of fulphuric acid combined with a peculiar fpecies of earth. This analyfis was foon after confirmed and extended by Bergman. The earth was at firft called *terra ponderofa*, *heavy earth*, on account of the great fpecific gravity of the fubftance from which it was obtained. Morveau called it *barote* (from *βαρυς*, *heavy*), which Bergman changed into *barytes*; and this laft term is now univerfally adopted.

Barytes.

210 Method of obtaining it. Barytes is generally found combined either with fulphuric or carbonic acid. From the firft of thefe compounds, which is by far the moft common, it may be obtained by the following procefs:

Reduce the mineral to a powder, and mix it with $2\frac{1}{2}$, its weight of carbonat of foda (T), previoufly deprived of all its water. Expofe the mixture to a red heat for an hour and a half, avoiding fufion, and a double decompofition takes place; the fulphuric acid unites with the foda, while the carbonic acid combines with the barytes. Wafh it in a fufficient quantity of water to diffolve the compound of fulphuric acid and foda, the carbonat of barytes, which is almoft infoluble, remains behind. Left it fhould be mixed with fome other earths, which is generally the cafe, boil it for three hours in ten times its weight of diftilled vinegar, the fpecific gravity of which is 1,033; by which the barytes will be diffolved, and likewife the lime and magnefia, if there happen to be any; but every other earth (U) remains untouched. Pour off the folution, and add to it fulphuric acid as long as any precipitate is formed. This precipitate confifts of the whole barytes and the lime (if there be any) combined with fulphuric acid. Wafh it in 50 times its weight of water, and all the lime will be diffolved. There will now remain nothing but barytes combined with fulphuric acid, which may be decompofed as before by carbonat of foda §. The carbonic acid may then be feparated by applying a very violent heat †; or, what is better, nitric acid may be poured upon it, which will feparate the carbonic acid and combine with the barytes; and then the nitric acid may be driven off by a moderate heat §.

§ *Afsvelius, Ann. de Chim.* iii.
† *Hope, Edin. Tranf.* iv. 36.
§ *Fourcroy* and *Vauquelin, Ann. de Chim.* xxi. 276.

211 Its properties. Barytes thus obtained is a light fpongy, porous, body, which may be very eafily reduced to powder. It has a harfh and more cauftic tafte than lime; and when taken into the ftomach, proves a moft violent poifon. It has no perceptible fmell.

Its fpecific gravity has not yet been afcertained.

It imbibes water with a hiffing noife, but, according to Dr Hope, without fwelling or fplitting as lime does ‖. However, when expofed to the air, as Fourcroy and Vauquelin inform us, it effloresces, cracks, burfts, fwells up, heats and becomes white, by abforbing moifture §.

‖ *Edin. Tranf. ibid.*
§ *Ann. de Chim. ibid.* and *Nicholfon's Jour.* i. 535.

Cold water diffolves about $\frac{1}{25}$ part of its weight of barytes, and boiling water more than half its weight. As the water cools, the barytes is depofited in cryftals, the fhape of which varies according to the rapidity with which they have been formed. When moft regular, they are flat hexagonal prifms, having two broad fides, with two intervening narrow ones, and terminated at each end by a four-fided pyramid, which in fome inftances conftitutes the larger part of the cryftal. When formed flowly, they are diftinct and large; but when the

(T) Soda is an alkali; which fhall be afterwards defcribed. Carbonat of foda is foda combined with carbonic acid, the common ftate in which it is obtained; potafs might alfo be ufed.

(U) Except ftrontites, which Pelletier has detected in this mineral.

Barytes. the water is faturated with barytes, they are depofited rapidly, and are generally more flender and delicate. Then, too, they are attached to one another in fuch a manner as to affume a beautiful foliacious appearance, not unlike the leaf of a fern ¶.

¶ *Hope, ibid.*

Thefe cryftals are tranfparent and colourlefs, and appear to be compofed of about 53 parts of water and 47 of barytes. When expofed to the heat of boiling water, they undergo the *watery fufion*, or, which is the fame thing, they melt without lofing any of the water which they contain. A ftronger heat makes the water fly off. When expofed to the air, they attract carbonic acid, and crumble into duft. They are foluble in $17\frac{1}{2}$ parts of water at the temperature of 60°; but boiling water diffolves any quantity whatever: the reafon of which is evident; at that temperature their own water of cryftallization is fufficient to keep them in folution§.

§ *Id.*

Water faturated with barytes is called *barytic water*. It has the property of converting vegetable blues to a green.

When barytes is expofed to the blow-pipe on a piece of charcoal, it fufes, bubbles up, and runs into globules, which quickly penetrate the charcoal‡. This is probably in confequence of containing water; for Lavoifier found barytes not affected by the ftrongeft heat which he could produce.

‡ *Fourcroy and Vauquelin, ibid.*

212
Sulphuret of barytes.

Barytes combines readily with fulphur. The eafieft way of forming fulphuret of barytes is to mix eight parts of fulphuret of barytes with one part of pounded charcoal, and to apply a ftrong heat. The charcoal combines with the oxygen of the fulphuric acid, and the compound flies off in the form of carbonic acid gas. There remains behind fulphur combined with barytes. Sulphuret of barytes is foluble in water: It is of a yellow colour. It is capable of cryftallizing; and then affumes a yellowifh white colour‖.

‖ *Fourcroy.*

The phofphuret of barytes has not been examined.

No mixture of barytes and lime, nor of barytes and magnefia is fufible in the ftrongeft heat which it has been poffible to apply§.

§ *Lavoifier, Acad. Par.* 1782.

213
Its affinities.

The affinities of barytes, according to Bergman, are as follows:

Sulphuric acid,
Oxalic,
Succinic,
Fluoric,
Phofphoric,
Saccholactic,
Suberic(v)?
Nitric,
Muriatic,
Sebacic,
Citric,
Tartarous,
Arfenic,
Fluoric,
Lactic,
Benzoic,
Acetous,
Boracic,
Sulphurous,
Nitrous,
Carbonic,
Pruffic,
Sulphur,
Phofphorus,
Water,
Fixed oils.

Sect. IV. *Of Strontites.*

Strontites.

214
Difcovery of ftrontites.

About the year 1787, a mineral was brought to Edinburgh by a dealer in foffils, from the lead mine of Strontian in Argylefhire, where it is found imbedded in the ore, mixed with feveral other fubftances. It is fometimes tranfparent and colourlefs, but generally has a tinge of yellow or green. Its hardnefs is 5. Its fpecific gravity varies from 3,4 to 3,726. Its texture is generally fibrous; and fometimes it is found cryftallized in flender prifmatic columns of various lengths‡.

‡ *Hope, Edin. Tranf.* iv. 44.

This mineral was generally confidered as a carbonat of barytes; but Dr Crawford having obferved fome differences between its folution in muriatic acid and that of barytes, mentioned in his treatife on *muriat of barytes*, publifhed in 1790, that it probably contained a new earth, and fent a fpecimen to Mr Kirwan that he might examine its properties. Dr Hope had alfo fufpected that its bafis differed from barytes; and accordingly he made a fet of experiments on it in 1791, which were read to the Royal Society of Edinburgh in 1792. Thefe experiments fully proved that it contained a peculiar earth. Mr Kirwan likewife analyfed the ftrontian mineral, and drew precifely the fame conclufions. It has been analyfed alfo by Mr Klaproth of Berlin, and Mr Pelletier of Paris. It confifts of carbonic acid combined with a peculiar earth, to which Dr Hope gave the name of *ftrontites*. This appellation we fhall adopt.

The carbonic acid may be feparated by a heat of 140° Wedgewood, and then the ftrontites remains behind*.

* *Kirwan's Miner.* i. 332.

215
Its properties.

Strontites has been found in Argylefhire in Scotland, near Briftol in England, and in Pennfylvania†. It has been found alfo in France and in Sicily. It is of a white colour. It has a pungent acrid tafte. When pounded in a mortar, the powder that rifes is offenfive to the noftrils and lungs‡. It is not poifonous‖.

† *Klaproth,* ii. fect. 39.
‡ *Hope, ibid.*
‖ *Pelletier.*

One hundred and fixty-two parts of water, at the temperature of 60°, diffolve nearly one part of it. The folution is clear and tranfparent, and converts vegetable blues to a green. Hot water diffolves it in much larger quantities; and as it cools the ftrontites is depofited in colourlefs tranfparent cryftals. Thefe are in the form of thin quadrangular plates, generally parallelograms, the largeft of which feldom exceeds one-fourth of an inch in length. Sometimes their edges are plain, but they oftener confift of two facets, meeting together and forming an angle like the roof of a houfe. Thefe cryftals generally adhere to each other in fuch a manner as to form a thin plate of an inch or more in length and half an inch in breadth. Sometimes they affume a cubic form. They contain about 68 parts in 100 of water. They are foluble in 51,4 parts of water, at the temperature of 60°. Boiling water diffolves nearly half its weight of them. When expofed to the air, they lofe their water, attract carbonic acid, and fall into powder*.

* *Hope, ibid.*

When ftrontites is thrown into water, it attracts it with

(v) Suberic acid decompofes muriat and nitrat of barytes. *Jamefon's Mineral. of Shetland and Arran.*

Silica.

with a hiſſing noiſe, much heat is produced, and it falls into powder much more rapidly than lime†.

† *Id.*

It combines with ſulphur either by fuſion in a crucible, or by being boiled with it in water. The ſulphuret is of a dark yellowiſh brown colour. It is ſoluble in water‡.

‡ *Id.*

216 Its affinities.

The affinities of ſtrontites, as aſcertained by Dr Hope, are as follows:

Sulphuric acid,
Oxalic,
Tartarous,
Fluoric,
Nitric,
Muriatic,
Succinic,
Phoſphoric,
Acetous,
Arſenic,
Boracic,
Carbonic.

Sect. V. *Of Silica.*

217 Method of obtaining ſilica.

If one part of powdered flints or ſand, mixed with three parts of potaſs, be put into a crucible, and kept in a ſtate of fuſion for half an hour, a brittle maſs will be formed almoſt as tranſparent as glaſs, which quickly attracts moiſture from the atmoſphere, and is entirely ſoluble in water. This ſolution is called *liquor ſilicum*, or *liquor of flints*. It was firſt accurately deſcribed by Glauber, a chemiſt, who lived about the middle of the 17th century.

If an acid be poured into this liquor, a white ſpongy ſubſtance is precipitated, which may be purified from every accidental mixture, by waſhing it in acids, muriatic acid for inſtance. This ſubſtance is called *ſiliceous earth*, or *ſilica*. It was firſt diſtinguiſhed as a peculiar earth by Pott in 1746, though it had been known long before; and Cartheuſer, Scheele, and Bergman proved in ſucceſſion that it could not, as ſome chemiſts had ſuppoſed, be reduced to any other earth.

218 Its properties.

Silica, when dried, is a ſoft white powder, without either taſte or ſmell.

Its ſpecific gravity is 2,66*.

* *Kirwan's Miner.* i. 10.

It is inſoluble in water except when newly precipitated from the liquor ſilicum, and then one part of it is ſoluble in 1000 parts of water†. It has no effect on vegetable colours.

† *Ibid.*

It is capable of abſorbing about one-fourth of its weight of water without letting any drop from it; but on expoſure to the air, the water evaporates very readily‡.

‡ *Ibid.*

Silica may be formed into a paſte with a ſmall quantity of water: this paſte has not the ſmalleſt ductility, and when dried, forms a looſe, friable and incoherent maſs§.

§ *Scheele.*

Silica is capable of aſſuming a cryſtalline form. Cryſtals of it are found in many parts of the world. They are known by the name of *rock cryſtal*. When pure they are tranſparent and colourleſs like glaſs: they aſſume various forms; the moſt uſual is a hexagonal priſm, ſurmounted with hexagonal pyramids on one or both ends, the angles of the priſm correſponding with thoſe of the pyramids. Their hardneſs is very great, amounting to eleven. Their ſpecific gravity is 2,653*.

* *Kirwan's Min.* i. 242.

There are two methods of imitating theſe cryſtals by art. The firſt method was diſcovered by Bergman. He diſſolved ſilica in fluoric acid, the only acid in which it is ſoluble, and allowed the ſolution to remain undiſturbed for two years. A number of cryſtals were then found at the bottom of the veſſel, moſtly of irregular figures, but ſome of them cubes with their angles truncated. They were hard, but not to be compared in this reſpect with rock cryſtal*.

* *Bergman*, ii. 32.

The other method was diſcovered by accident. Profeſſor Seigling of Erfurt had prepared a liquor ſilicum, which was more than uſually diluted with water, and contained a ſuperabundance of alkali. It lay undiſturbed for eight years in a glaſs veſſel, the mouth of which was only covered with paper. Happening to look to it by accident, he obſerved it to contain a number of cryſtals, on which he ſent it to Mr Trommſdorf, profeſſor of chemiſtry at Erfurt, who examined it. The liquor remaining amounted to about two ounces. Its ſurface was covered by a tranſparent cruſt ſo ſtrong that the veſſel might be inverted without ſpilling any of the liquid. At the bottom of the veſſel were a number of cryſtals, which proved on examination to be ſulphat of potaſs and carbonat of potaſs (w). The cruſt on the top conſiſted partly of carbonat of potaſs, partly of cryſtallized ſilica. Theſe laſt cryſtals had aſſumed the form of tetrahedral pyramids in groups; they were perfectly tranſparent, and ſo hard that they ſtruck fire with ſteel.†

† *Nicholſon's Jour.* i. 217.

Silica endures the moſt violent heat without alteration.

It ſeems incapable of combining with ſulphur or phoſphorus.

219 Effect of heat on mixtures of lime and ſilica;

1. The effect of heat upon lime and ſilica, mixed in various proportions, will appear from the following experiments of Mr Kirwan‡.

‡ *Mineral.* i. 56.

Proportions.	Heat.	Effect.
50 Lime 50 Silica	150° Wedg.	Melted into a maſs of a white colour, ſemitranſparent at the edges, and ſtriking fire, tho' feebly, with ſteel: it was ſomewhat between porcelain and enamel.
80 Lime 20 Silica	156	A yellowiſh white looſe powder.
20 Lime 80 Silica	156	Not melted, formed a brittle maſs.

220 Magneſia and ſilica:

2. Equal parts of magneſia and ſilica melt with great difficulty into a white enamel when expoſed to the moſt violent heat which can be produced*. They are infuſible in inferior heats in whatever proportion they are mixed†.

* *Lavoiſier, Mem. Par.* 1787, p. 598.

† *Achard, Mem. Berl.* 1780, p. 33.

221 Barytes and ſilica;

3. The effect of heat on various mixtures of barytes and ſilica will appear from the following experiments of Mr Kirwan‡.

‡ *Mineral.* i. 57.

Proportions.

(w) Potaſs combined with ſulphuric acid and with carbonic acid.

Silica.

Proportions.	Heat.	Effect.
80 Silica 20 Barytes	155° Wedg.	A white brittle maſs.
75 Silica 20 Barytes	150	A brittle hard maſs, ſemitranſparent at the edges.
66 Silica 33 Barytes	150	Melted into a hard ſomewhat porous porcelain maſs.
50 Silica 50 Barytes	148	A hard maſs not melted.
20 Silica 80 Barytes	148	The edges were melted into a pale greeniſh matter between a porcelain and enamel.
25 Silica 75 Barytes	150	Melted into a ſomewhat porous porcelain maſs.
33 Silica 66 Barytes	150	Melted into a yellowiſh and partly greeniſh white porous porcelain.

4. The effect of heat on mixtures of ſtrontites and ſilica is not known.

222 And lime, magneſia, and ſilica.

5. It follows from the experiments of Achard, that equal parts of lime, magneſia, and ſilica, may be melted into a greeniſh coloured glaſs, hard enough to ſtrike fire with ſteel; that when the magneſia exceeds either of the other two, the mixture will not melt; that when the ſilica exceeds, the mixture ſeldom melts, only indeed with him in the following proportions; three ſilica, two lime, one magneſia, which formed a porcelain; and that when the lime exceeds, the mixture is generally fuſible.*

* *Mem. Berl. ibid.* and *Jour. de Phyſ.* xxiv.

223 Affinities of ſilica.

The affinities of ſilica are as follows:

Fluoric acid,
Fixed alkali.

SECT. VI. *Of Alumina.*

224 Method of obtaining alumina.

DISSOLVE alum in hot water, and add to the ſolution potaſs as long as any precipitate is formed. Decant off the fluid part, and waſh the precipitate in a ſufficient quantity of water, and then allow it to dry. The ſubſtance thus obtained is called *alumina*. Its properties were firſt aſcertained with accuracy by Margraf.

225 Its properties.

Alumina thus obtained is a very white ſpongy powder, without any ſmell or taſte.

Its ſpecific gravity is 2,00†. It is ſcarcely ſoluble in water, but may be diffuſed through it with great facility.

† *Kirwan's Miner.* i. 9.

Alumina.

With a ſmall quantity of water it forms a very tough ductile paſte, and does not readily mix with more.

In its uſual ſtate of dryneſs it is capable of abſorbing 2½ times its weight of water, without ſuffering any to drop out. It retains this water more obſtinately than any of the earths hitherto deſcribed. In a freezing cold it contracts more, and parts with more of its water than any other earth; a circumſtance which is of ſome importance in agriculture.*

* *Ibid.*

Alumina has never yet been obtained in a cryſtallized form. It has no effect whatever on vegetable colours.

The moſt intenſe heat does not fuſe it, but it has the ſingular property of diminiſhing in bulk in proportion to the intenſity of the fire to which it is expoſed. It becomes at the ſame time exceedingly hard: Mr Lavoiſier rendered it capable of cutting glaſs; and Mr Boyle had long before done the ſame thing.*

* *Shaw's Boyle*, iii. 422.

226 Wedgewood's thermometer.

Wedgewood took advantage of this property of alumina, and by means of it conſtructed an inſtrument for meaſuring high degrees of heat. It conſiſts of pieces of clay of a determinate ſize, and an apparatus for meaſuring their bulk with accuracy: One of theſe pieces is put into the fire, and the temperature is eſtimated by the contraction of the piece. For a more complete deſcription of this important inſtrument, we refer to the article THERMOMETER in the *Encycl.*

Alumina is hardly ſuſceptible of combining with ſulphur or phoſphorus; but from the experiments of La Grange, it appears to have an affinity for carbon‡.

‡ *Nicholſon's Jour.* ii. 101.

1. The effect of heat on various mixtures of lime and alumina will appear from the following table§.

§ *Kirwan*, i. 56.

227 Effect of heat on mixtures of lime and alumina;

Proportions.	Heat.	Effect.
75 Lime 25 Alumina	150° Wedg.	Not melted.
66 Lime 33 Alumina	150	Remained a powder.
33 Lime 66 Alumina	(x)	Melted.
25 Lime 75 Alumina	(x)	Melted.
20 Lime 80 Alumina	(x)	Melted.

228 Magneſia and alumina;

2. Magneſia and alumina have no action whatever on each other, even when expoſed to a heat of 150° Wedgewood.*

* *Ibid.* i. 57.

229 Barytes and alumina;

3. The effect of heat on different mixtures of barytes and alumina will appear from the following experiments of Mr Kirwan†.

† *Ibid.*

 Proportions.

(x) Theſe three experiments were made by Ehrman: The heat was produced by directing a ſtream of oxygen gas on burning charcoal, and is the moſt intenſe which it has been hitherto poſſible to produce.

Alumina.

Proportions.	Heat.	Effect.
80 Alumina 20 Barytes	150° Wedg.	Scarcely hardened.
75 Alumina 25 Barytes	156	No sign of fusion, a loose powder.
66 Alumina 33 Barytes	152	As the former.
50 Alumina 50 Barytes	150	As the former.
20 Alumina 80 Barytes	148	Somewhat harder, but no sign of fusion.
25 Alumina 75 Barytes	150	Harder, but no sign of fusion.

4. Nothing is known concerning the effect of heat on mixtures of strontites and alumina.

230 Alumina and silica; * Kirwan's Min. i. 58.

5. Equal parts of alumina and silica harden in the temperature of 160° Wedgewood, but do not fuse. Achard found them infusible in all proportions in a heat probably little inferior to 150° Wedgewood. Mixtures of these two earths in various proportions form *clays*, but these are seldom uncontaminated with some other ingredients.

231 Lime, magnesia, and alumina:

6. From the experiments of Achard, it appears that no mixture of lime, magnesia, and alumina, in which the lime predominates, is vitrifiable, except they be nearly in the proportions of three lime, two magnesia, one alumina; that no mixture in which magnesia predominates will melt in a heat below 166°; that mixtures in which the alumina exceeds are generally fusible, as will appear from the following table†:

† Ibid. i. 72.

3 Alumina 2 Lime 1 Magnesia	A porcelain.
3 Alumina 1 Lime 2 Magnesia	A porcelain.
3 Alumina 1 Lime 3 Magnesia	Porous porcelain.
3 Alumina 2 Lime 3 Magnesia	Porous porcelain.
3 Alumina 2 Lime 2 Magnesia	Porcelain.

232 Lime, silica, and alumina;

7. From the same experiments, and those of Kirwan, we learn, that, in mixtures of lime, silica, and alumina, when the lime exceeds, the mixture is generally fusible either into a glass or a porcelain, according to the proportions. The only infusible proportions were,

2	3	Lime
1	1	Silica
2	2	Alumina

That if the silica exceeds, the mixture is frequently fusible into an enamel or porcelain, and perhaps a glass; and that when the alumina exceeds, a porcelain may often be attained, but not a glass‡.

‡ Ibid. i. 73.

233 Magnesia, silica, and alumina;

8. As to mixtures of magnesia, silica, and alumina, when the magnesia exceeds, no fusion takes place at 150°. When the silica exceeds, a porcelain may often be attained; and three parts silica, two magnesia, and one alumina, formed a glass. When the alumina exceeds, nothing more than a porcelain can be produced.*

* Ibid. i. 72.

234 And Lime, magnesia, silica, and alumina.

9. Achard found that equal parts of lime, magnesia, silica, and alumina, melted into a glass. They fused also in various other proportions, especially when the silica predominated.

235 Affinities of alumina.

The affinities of alumina are as follows:

Sulphuric acid,
Nitric,
Muriatic,
Oxalic,
Arsenic,
Fluoric,
Sebacic,
Tartarous,
Succinic,
Saccholactic,
Citric,
Phosphoric,
Formic,
Lactic,
Benzoic,
Acetous,
Boracic,
Sulphurous,
Nitrous,
Carbonic,
Prussic.

Sect. VII. *Of Jargonia.*

236 Discovery of jargonia.

Among the precious stones which come from the island of Ceylon, there is one called *jargon*, which is possessed of the following properties.

Its colour is various, grey, greenish white, yellowish, reddish brown, and violet. It is often crystallized, either in right angular quadrangular prisms surmounted with pyramids, or octahedrals consisting of double quadrangular pyramids. It has generally a good deal of lustre, at least internally. It is mostly semitransparent. Its hardness is from 10 to 16: Its specific gravity from 4,416 to 4,7.*

* Ibid. i. 333.

It loses scarcely any of its weight in a melting heat; for Klaproth found that 300 grains, after remaining in it for an hour and a half, were only one-fourth of a grain lighter than at first†. Neither was it attacked either by muriatic or sulphuric acid, even when assisted by heat. At last, by calcining it with a large quantity of soda, he dissolved it in muriatic acid, and found that 100 parts of it contained 31,5 of silica, five of a mixture of nick-

† Jour. de Phys. 36. 180.

el and iron, and 68 of an earth poffeffed of peculiar properties. This earth has been called *jargonia*.

237 Its properties.

Jargonia has a ftrong refemblance to alumina. It is of a white colour. Its fpecific gravity probably exceeds 4,000.

It differs from alumina in the compounds which it forms with other bodies, in being infoluble in a boiling folution of pure potafs or foda, and in being infufible by heat when mixed with thefe fubftances in a ftate of drynefs‡.

‡ *Kirwan's Mineral.* i. p. 14.

No more of its properties are yet known.

Sect. VIII. *Of Adamanta.*

238 Difcovery of adamanta.

There is a ftone found in China and in the Eaft Indies near Bombay, which from its hardnefs has been called *adamantine fpar*. Mr Greville firft received fome fpecimens of it, and made it known to feveral French and Englifh naturalifts.

The variety which comes from China is cryftallized in hexagonal prifms. It is of a grey colour. The entire pieces are opaque, but thin plates of it are tranfparent. It is fo hard, that it not only cuts glafs as eafily as the diamond, but even fcratches rock cryftal and many other very hard ftones. Its fpecific gravity is 3,710 The variety which comes from Bombay, and which is whiter than the other, is called *corundum**.

* *Klaproth, Ann. de Chim.* i. 188.

Mr Greville fent fome fpecimens of this ftone to Mr Klaproth, that he might analyfe it: a tafk which he found very difficult to perform, for the common proceffes had no effect upon it. At laft he fucceeded by fufing it 12 times in a filver crucible with 15 parts of foda, and expofing it each time for five hours to the ftrongeft heat which the crucible could endure. After each fufion he foftened the mafs with boiling water, precipitating by acids the earth which the foda had diffolved. He digefted alfo different times the undecompofed part in boiling acids. By this procefs he decompofed it, and found that it was compofed of two parts of alumina, and one of a peculiar earth which has been called *adamanta*.

239 Its properties.

This earth he at firft took for filica; but it differs from it in not being infufible when mixed with potafs or foda. Its fpecific gravity probably exceeds 3,00†. Nothing more is known concerning its properties.

† *Kirwan's Mineral.* i. 17.

240 Glucina.

A new earth has lately been difcovered by Mr Vauquelin in the beryl, to which he has given the name of *glucina*. His account of its properties we have not hitherto been able to procure: we muft therefore referve our defcription of it till we come in the order of the alphabet to the word Glucina.

241 Sidneia.

Thefe are all the fimple earths hitherto difcovered; for *Sidneia*(y), which was announced by Mr Wedgewood as a peculiar earth, has lately been proved by Mr Hatchet* to be merely a mixture of feveral earths which have been long known.

* *Phil. Tranf.* 1798.

242 Remarks on the earths.

The firft four earths have a great many common properties: they tinge vegetable blues green, they have a ftrong affinity for carbonic acid, and combine readily with all acids. They have fometimes been called *alkaline earths*.

There is a ftrong refemblance between filica and adamanta, and between alumina and jargonia.

None of the earths have been hitherto decompounded, nor has the fmalleft proof ever been brought that they are compounds. We muft therefore, in the prefent ftate of chemiftry, confider them as fimple bodies. Many attempts, indeed, have been made to fhew that there was but one earth in nature, and that all others were derived from it. The earth generally made choice of as the fimpleft was filica(z). But none of thefe attempts, notwithftanding the ingenuity of feveral of the authors, has been attended with the fmalleft fhadow of fuccefs.

We have mentioned formerly that it was almoft the univerfal opinion of chemifts that metals were compofed of fome of the earths united to phlogifton; but of late an attempt has been made to prove that all the earths are metallic oxyds, and that they can actually be reduced to the ftate of metals.

Baron had long ago fufpected that alumina had fomewhat of a metallic nature; and Bergman had been induced by its great weight, and feveral other appearances, to conjecture that barytes was a metallic oxyd: But the firft chemift who ventured to hint that all earths might be metallic oxyds was Mr Lavoifier*. About the year 1790, foon after the publication of Mr Lavoifier's book, Mr Tondi and Profeffor Ruprecht, both of Schemnitz, announced that they had obtained from barytes, by the application of a ftrong heat, a metal of the colour of iron, and attracted by the magnet, which they called *borbonium*; from magnefia another, which they called *auftrum*; a third from lime, alfo called *auftrum*; and a fourth from alumina, which they denominated *apulum*. Their method of proceeding was to apply a violent heat to the earths, which were furrounded with charcoal in a Heffian crucible, and covered with calcined bones in powder.

* *Chemiftry*, p. 217. Englifh tranfl.

But their experiments were foon after repeated by Klraproth, Savorefi, and Tihaufki; and thefe accurate chemifts foon proved, that the pretended metals were all of them *phofphurets of iron*. The iron, by the violence of the heat had been extracted from the crucible, and the phofphorus from the bones. The earths therefore muft ftill continue a diftinct clafs of bodies: and, as Klaproth has obferved, their properties are fo exceedingly different from thofe of metallic oxyds, that the fuppofition of their being compofed of the fame ingredients is contrary to every fact, and to every analogy with which we are acquainted.

Chap. V. *Of* Caloric.

Nothing is more familiar to us than *heat*; to attempt to define it therefore would be unneceffary. When we fay that *a perfon feels heat*, that *a ftone is hot*, the expreffions

(y) This fubftance was contained in a mineral brought from Sidney Cove in New-Holland. Wedgewood's analyfis was publifhed in 1790. Klaproth afterwards analyfed it without finding the new earth which it had been fuppofed to contain. But doubts were entertained concerning the identity of the minerals examined by thefe two philofophers. Thefe doubts have been removed by Mr Hatchet.

(z) Mr Sage, however, pitched upon lime.

expreſſions cauſe no difficulty; every one underſtands them perfectly: yet in each of theſe propoſitions the word *heat* has a diſtinct meaning. In the one it ſignifies the *ſenſation* of heat: in the other, the *cauſe* of that ſenſation. This ambiguity, though of little conſequence in common life, leads unavoidably in philoſophical diſcuſſions to confuſion and perplexity. It was to prevent this that the French chemiſts made choice of the word *caloric* to ſignify the *cauſe of heat*. When I put my hand on a hot ſtone, I experience a certain ſenſation, which I call the *ſenſation of heat*; the cauſe of this ſen-
243 ſation is *caloric*.

Whether caloric be a ſubſtance.

Concerning the nature of caloric, there are two opinions which have divided philoſophers ever ſince they turned their attention to the ſubject. Some ſuppoſe that caloric, like gravity, is merely a property of matter, and that it conſiſts, ſome how or other, in a peculiar vibration of its particles; others, on the contrary, think that it is a diſtinct ſubſtance. Each of theſe opinions has been ſupported by the greateſt philoſophers; and the obſcurity of the ſubject is ſuch that both ſides have been able to produce exceedingly plauſible and forcible arguments (13). The recent diſcoveries, however, in this branch of chemiſtry, have rendered the latter opinion much more probable than the former. Indeed we do not ſee how it is poſſible to account for many of the phenomena of nature, unleſs caloric be conſidered as a ſubſtance, as we truſt ſhall appear from the inveſtigation into which we are about to enter. We mean, then, with the generality of modern chemiſts, to take it for granted, that caloric is a ſubſtance, without pretending to be able to demonſtrate the truth of our opinion, but merely becauſe we conſider it as infinitely more plauſible than the other. If the receiver of an air-pump, while it contains a thermometer, be ſuddenly exhauſted of air, the thermometer ſinks ſeveral degrees, and then gradually riſes again to its former height. Now if heat be owing to vibration, how comes it that the ſmall quantity of matter remaining in the receiver is firſt inſufficient, and afterwards ſufficient to maintain the temperature? Is it not more probable that part of the caloric was carried off with the air, and that it gradually returned through the glaſs, which it is capable of pervading, though with difficulty*. When air is let into an exhauſted receiver, the thermometer, as Lambert firſt obſerved, riſes ſeveral degrees. Is not this owing to an additional quantity of caloric introduced by the air? The thermometer then ſinks ſlowly. Is not this becauſe the ſuperabundant caloric gradually pervades the glaſs and flies off? Taking it for granted then, that caloric is a ſubſtance, we proceed to examine its properties.

* See *Pictet ſur le Feu*, ch. ii.

244 Caloric expands bodies.

1. When bodies become hot, or which is the ſame thing, when caloric enters into them, they expand in every direction; and this expanſion is proportional to the accumulation of caloric. The firſt and moſt obvious property of caloric then is the power of expanding bodies. It does not, however, expand all ſubſtances equally, and we are ſtill ignorant of the law which it follows. All that can be done therefore is to collect facts till this law be diſcovered. A number of theſe may be ſeen in the following table:

TABLE *of the Expanſion of various Bodies at different Temperatures.*

* Blagden. † Newton.

From

(A) This mark ‡ implies, that, owing to some inaccuracy in making the experiments, the numbers to which it is attached are not to be depended on.

(B) The metal whose expansion is here given was an alloy composed of three parts of copper and one of tin. The figures in some of the preceding columns are to be understood in the same manner. Thus in the last column but two, the metal consisted of two parts of brass alloyed with one of zinc.

Caloric.

245 Exception. From this table, it appears that the gases are more expanded by caloric than fluids, and fluids more than solids; and that the expansion of all bodies hitherto examined, mercury alone excepted, goes on in an increasing series. To the expanding power of caloric there is one singular exception: From 30° to 40° Fahrenheit, *water*, instead of being expanded, suffers a remarkable contraction, as is evident from the following table of its bulk for every degree between 30° and 40.

* Blagden.

From 40° it expands like other substances on being heated (B).

246 Thermometer. The expansion of bodies by caloric has furnished us with an instrument for measuring the various degrees of it in different substances, we mean the thermometer; and as mercury is the only fluid which expands equably, it is obviously the only proper one for thermometers (14). The thermometer uniformly used in this article is that of Fahrenheit, except when some other is particularly mentioned.

247 No body without caloric. 2. By means of the thermometer, we learn that there is no body which does not contain caloric, because there is none so cold that it cannot be made colder: and cooling a body is nothing else but abstracting a part of the caloric which it contains.

248 Equilibrium of caloric. 3. Caloric cannot be confined in any body while those in its neighbourhood are colder, but continues to rush out till every thing is reduced to the same temperature. This does not proceed from the attraction of the colder bodies, but from the tendency of caloric to exist everywhere in an equal degree of tension: For when hot bodies are placed in the exhausted receiver of an air-pump, as we learn from Mr Pictet †, or in the Torricellian vacuum, as Count Rumford has shewn us ‡, the caloric leaves them in the same manner, tho' more slowly, and they are equally reduced to the temperature of the surrounding bodies. This property has been called *the equilibrium of caloric*. The only way therefore to confine or accumulate this substance in a body, is to surround it with bodies which are hotter than itself.

† Sur le Feu, chap. vi.

‡ Phil. Trans. 1786, Part I.

249 The particles of caloric repel each other. 4. The equilibrium of caloric seems evidently to prove that its particles repel each other (15). This repulsion will cause them when accumulated in any place to fly off in every direction, and to continue to separate till they are opposed by caloric in other bodies of the same relative density with themselves, which, by repelling them in its turn, compels them to continue where they are. The caloric in bodies therefore is in what has been called by Mr Pictet a state of *tension* (c). Its particles are actuated by a force which would make them separate to an indefinite distance, were they not confined by the opposite force of the caloric which surrounds them. The *equilibrium* therefore depends on the balancing of two opposite forces; the repulsion between the particles of caloric in the body, which tends to diminish the temperature; and the repulsion between the caloric of the body and the surrounding caloric, which tends to raise the temperature. When the first force is greater than the second, as is the case when the temperature of a body is higher than that of the surrounding bodies, the caloric flies off, and the body becomes colder. When the last force is stronger than the first, as is the case when a body is colder than those which are around it, the particles of its caloric are obliged to approach nearer each other, new caloric enters to occupy the space which they had left, and the body becomes hotter. When the two forces are equal, the bodies are said to be of the same temperature, and no change takes place.*

* See Pictet sur le Feu, ch. i.

It is the action of these opposite forces which makes the thermometer a measure of temperature. When applied to any body, it continues to rise or fall till the caloric in it and in the body to which it is applied are of the same tension, and then it remains stationary. The thermometer therefore merely indicates that the temperature of the body to which it is applied is equal to its own. It is obvious that, in order to obtain the real temperature of bodies, the thermometer should be so small that the quantity of caloric, which enters or leaves it, may not materially affect the result.

This property of caloric seems to be the cause of the elasticity of the gases, in which, as we shall shew afterwards,

---

(B) There was a curious fact concerning dilatation observed by Mr de Luc. A brass rod which he used as a thermometer became in summer *habitually* longer; that is to say, that after being for some time lengthened by heat, it did not contract by the application of cold to its old length, but continued somewhat longer. In winter the contrary phenomenon took place. After being contracted for some time by cold, it did not return to its old length on the application of heat, but kept somewhat shorter. A leaden rod shewed these effects in a greater degree. Glass has not this quality. De Luc suspects that this property is inversely as the elasticity of bodies. Glass is perfectly elastic, and lead is less elastic than brass.—*Journ. de Phys.* xviii. 369.

(14) Mercury does *not* expand regularly even according to the tables just given. For every five degrees it there appears that, in most instances, it expands 50.9, but betwixt 35° and 40° it expands 51. and between 50° and 55° it even expands 70.9, although betwixt 55° and 60° it expands again but 50.9. But this is not the only irregularity the thermometer is liable to. Glass is very irregular in its expansion. The tube and bulb therefore in which the mercury is contained must by their irregular expansions and contractions render this instrument inaccurate. T. P. S.

(15) Why need we consider caloric as a *principle of repulsion* when we can otherwise explain all its phenomena. T. P. S.

(c) The phrase was first used by Mr Volta.

Caloric. wards, it exists in great quantities. Perhaps it is the cause of elasticity in general; for we have no demonstrative evidence that the particles of elastic bodies repel each other (D), and we are certain that all of them contain caloric. Perhaps also it is owing to this repulsive property of caloric that the particles of no body actually touch each other; for the less caloric we leave in a body, the nearer its particles approach to one another. The expansion of bodies by caloric seems also to depend on the same property. The particles of caloric uniting with those of the body, endeavour to drag them along when they recede from each other. The expansion of bodies therefore ought to be inversely as their cohesion, and directly as the tension of the caloric which they contain. This property of caloric seems likewise to afford an explanation of a very curious fact, which was first, we believe, mentioned by De Luc in his Treatise

250 on the Modifications of the Atmosphere, and afterwards

Bodies become lighter by being heated, ascertained by Dr George Fordyce, that bodies become absolutely lighter by being heated. He took a glass globe three inches in diameter, with a short neck, and weighing 451 grains; poured into it 1700 grains of water from the New river, London, and then sealed it hermetically. The whole weighed 2150$\frac{11}{16}$ grains at the temperature of 32°. It was put for twenty minutes into a freezing mixture of snow and salt till some of it was frozen; it was then, after being wiped first with a dry linen cloth, next with clean washed dry leather, immediately weighed, and found to be $\frac{1}{16}$th of a grain heavier than before. This was repeated exactly in the same manner five different times. At each, more of the water was frozen and more weight gained. When the whole water was frozen, it was $\frac{3}{16}$ths of a grain heavier than it had been when fluid. A thermometer applied to the globe stood at 10°. When allowed to remain till the thermometer rose to 32°, it weighed $\frac{2}{16}$ths of a grain more than it did at the same temperature when fluid. We shall shew afterwards that ice contains less caloric than water of the same temperature with it. The balance used was nice enough to mark $\frac{1}{1000}$th part of a grain*. Morveau too found, much about the same time, that water put into vessels hermetically sealed weighed more when frozen than when fluid†: and Mr Chaussier found, that two pounds of sulphuric acid were three grains heavier when frozen than after they had recovered their fluidity‡. Now if the particles of caloric repel each other, bodies which contain it in great quantities must be somewhat repelled by each other. The more replete therefore that any

251 body is with caloric, the more it will be repelled by the

And why. earth, which always contains a great quantity; and this repulsion must in some degree counteract its gravitation. This explanation was first suggested, we believe, by Dr Black (16).

† Journ. de Phys. 1785, Oct.

‡ Journ. de Savans, 1785, p. 493.

252 Caloric moves more readily upwards than downwards.

The same property explains another curious fact discovered by Mr Pictet of Geneva, that caloric moves more readily vertically upwards than downwards. He took a tube of tinplate, two inches in diameter and 44 in length, and inclosed in it a bar of copper four lines in diameter and 33 inches in length, which was placed and fixed exactly in its axis. This tube was exhausted of air, by means of an air-pump, till the manometer* stood at the height of four lines. It was inclosed in another tube of pasteboard, except about two inches, exactly in the middle, to which place the sun's rays were directed for half an hour by means of a concave mirror. The ends of the copper bar were scooped out into concave hemispheres; and into each of these the bulb of a very sensible thermometer was fixed. The tube was placed vertically. The highest thermometer, which we shall call A, rose to 95°, a hundred and one seconds before the lowest B. The thermometer B rose no higher than 95°; but the thermometer A reached 101,75°. To see whether this difference was owing to the thermometers, the tube was inverted, and consequently the highest thermometer in the former experiment was lowest in this. The thermometer B now rose from 49° to 97,25° in 2810″; the thermometer A in 2763″, or 47″ sooner than B. It was evident from this result, that the thermometer A was more sensible than the thermometer B by 47″. If this be subtracted from 101″, the former difference, it will leave 54″, as the difference resulting from position. These experiments were repeated with only this difference, that round the ends of the bar and the bulbs of the thermometers (but without touching the bulbs) some folds of oiled paper were wrapped to confine the caloric. The superior thermometer A rose from 50° to 106,25° in 34 minutes, which was 93″ sooner than the inferior B: it rose to 110,75°, the thermometer B only to 106,25°. The tube being reversed, the thermometer A, which was now lowest, rose from 46° to 115,25° in 40′ 30′, or forty seconds sooner than the thermometer B. This subtracted from 93″, as formerly, leaves 53′ for the difference of situation. The superior thermometer mounted after the burning glass was removed 0,45°, remained stationary for 80″, and after five minutes had only descend 0,45°: the other did not ascend at all; in one minute it descended 0,225°, and in 6′ 8″ it descended 2,47. In 22′ 50″ the inferior descended 63,725°, the superior 61,475°*. From these experiments, it is obvious that the particles of caloric move somewhat faster, and in somewhat greater

* See Manometer in this Suppl.

* Pictet sur le Feu, chap. 2.

(D) We acknowledge that several philosophers of the first rank, Æpinus for instance, and Boscovich, have supposed, that the particles of all bodies both attract and repel each other; but we cannot help thinking it rather improbable (if it be possible) that two such opposite properties should exist together.

(16) We may, I think, explain these experiments without the aid of supposing caloric to possess absolute *levity*. While these gentlemen were weighing their vessels of frozen fluids, the caloric of the surrounding air kept constantly passing in, and thus it became condensed; this air would of consequence fall through the more rarified air below it and would be followed by a fresh quantity from above, which would be condensed in its turn, thus a constant stream of air would pass down on the cold body which would be sufficient to give it the small additional tendency of $\frac{3}{16}$ths of a grain downwards. Neither do these gentlemen appear to have paid any attention to the water which would be deposited, by the air, when it lost part of its caloric, on the vessels.
T. P. S.

Caloric.

er quantity, upwards than downwards; owing, doubtleſs, to the repulſive power of the caloric in the earth. The ſmall quantity of air that remained in the tube, may perhaps be ſuppoſed ſufficient to account for the difference, without allowing any ſuch tendency upwards in caloric. But it is evident from the experiments of the Florentine academicians on the ſame ſubject, with tubes full of air, that even when in great abundance, that fluid hardly affected the riſing of the ſuperior thermometer: ſurely then its effect muſt be altogether imperceptible when ſo little of it remained; and in the third and fourth experiments the oiled paper prevented any of the heated air from approaching the thermometer (17).

253 Conducting power of bodies:

5. If we take a bar of iron and a piece of ſtone of equal dimenſions, and putting one end of each into the fire, apply either thermometers or our hands to the other, we ſhall find the extremity of the iron ſenſibly hot long before that of the ſtone. Caloric therefore does not paſs through all bodies with the ſame celerity and eaſe. The power that bodies have to allow it a paſſage through them is called their *conducting power*; thoſe that allow it to paſs with facility, are called *good conductors*; thoſe through which it paſſes with difficulty, are called *bad conductors*; and thoſe which do not allow it to paſs at all, *non-conductors*.

254 Of wood and charcoal;

It is probable that all ſolids conduct heat in ſome degree, at leaſt this is the caſe with every one at preſent known. Wood and charcoal are exceeding bad conductors of caloric (E). Count Rumford informs us, that a piece of green oak plank was employed to ſtir the melted metal of which cannons were founding at Munich, and it was often allowed to remain a conſiderable time in the furnace; yet the caloric had penetrated to ſo inconſiderable a depth, that at the diſtance of $\frac{1}{20}$th of an inch below the ſurface, the wood did not ſeem to have been the leaſt affected by it; the colour remained unchanged, and it did not appear to have loſt even its moiſture*.

* *Rumford's Eſſays*, ii. 229.

255 Of glaſs;

Glaſs is alſo a very bad conductor; and this is the reaſon that it is ſo apt to crack on being heated or cooled ſuddenly; one part of it receiving or parting with its caloric before the reſt, expands or contracts, and deſtroys the coheſion.

256 Of metals;

Metals are the beſt conductors of caloric of all the ſolids hitherto examined. The conducting powers of all, however, are not equal. Dr Ingenhouſz procured cylinders of ſeveral metals exactly of the ſame ſize, and having coated them with wax, he plunged their ends into hot water, and judged of the conducting power of each by the length of wax-coating melted. From theſe experiments he concluded, that the conducting powers of the metals which he examined were in the following order*:

Silver,
Gold,
Copper, } nearly equal,
Tin,
Platinum, } much inferior to the others.
Iron,
Steel,
Lead,

* *Journ. de Phyſ.* 1789, p. 68.

257 Of ſtones and ſolids capable of melting.

Next to metals ſtones ſeem to be the beſt conductors; but this property varies conſiderably in different ſtones. Bricks are much worſe conductors than moſt ſtones. All ſolids capable of being melted become non conductors the moment they are heated to the melting point: the caloric enters them eaſily enough, but it remains in them.

258 All fluids non-conductors of caloric.

All fluids hitherto examined are *non conductors of caloric*. They can receive it indeed from other ſubſtances, and they can give it out to other ſubſtances; but one particle can neither receive it nor give it out to another particle. Before a fluid therefore can either be heated or cooled, every particle muſt go individually to the ſubſtance from which it receives or to which it gives out caloric. For this very important diſcovery the world is indebted to Count Rumford. Before the publication of his eſſays it had not even been ſuſpected; ſo far from it, that fluids had been ranked among the beſt conductors of caloric.

259 How this was diſcovered.

In a ſet of experiments on the communication of heat, he made uſe of thermometers of an uncommon ſize. Having expoſed one of theſe (the bulb of which was near four inches in diameter) filled with alcohol to as great a heat as it could ſupport, he placed it in a window to cool where the ſun happened to be ſhining. Some particles of duſt had by accident been mixed with the alcohol: theſe being illuminated by the ſun, became perfectly viſible, and diſcovered that the whole liquid in the

(17) Theſe experiments of Mr Pictet are undoubtedly ingenious, but by no means concluſive. There ſtill remained a conſiderable quantity of air in the tube. This air became rarified juſt in the centre of the tube where the mirror converged the ſun's rays. Hence this air would riſe up to the top of the tube, and part with its extra quantum of heat to the upper thermometer. This air would be replaced from above, and thus a conſtant ſtream of warm air towards the upper thermometer would be produced. Thus might we account for the riſe of the upper thermometer without the aid of a *principle of levity*. That the lower thermometer ſhould riſe but ſlowly is not ſurpriſing when we conſider the experiments of Count Rumford on the conducting powers of air, which, *at leaſt*, prove it to be a *very bad* conductor of caloric. The oiled paper not preventing the thermometer riſing is no proof that it is not this ſtream of warm air which cauſes the upper thermometer to riſe, unleſs it be proved that it is a non-conductor of caloric, and if it were I do not ſee how the caloric is to get through to the thermometer eaſier if it poſſeſſes abſolute *levity* than if it be a gravitating fluid. All, I think, theſe experiments prove is, that the ſpecific gravity of caloric is leſs than that of the imperfect vacuum Mr Pictet made uſe of. T. P. S.

(E) This fact merits the attention of chemiſts. It is obvious, that when metallic oxyds are ſurrounded with charcoal powder, their temperature cannot be raiſed near ſo high as it otherwiſe would be. It is not unlikely that ſome part of the difficulty which has been experienced in attempting to reduce and fuſe ſeveral metallic ſubſtances may have been owing to this cauſe.

Caloric.

the tube of the thermometer was in a most rapid motion, running swiftly in opposite directions upwards and downwards at the same time. The *ascending* current occupied the axis, the *descending* current the sides of the tube. When the sides of the tube were cooled by means of ice, the velocity of both currents was accelerated. It diminished as the liquid cooled; and when it had acquired the temperature of the room, the motion ceased altogether. This experiment was repeated with linseed oil, and the result was precisely the same. These currents were evidently produced by the particles of the liquid going individually to the sides of the tube, and giving out their caloric. The moment they did so, their specific gravity being increased, they fell to the bottom, and of course pushed up the warmer part of the fluid, which was thus forced to ascend along the axis of the tube. Having reached the top of the tube, the particles gave out part of their caloric, became specifically heavier, and tumbled in their turn to the bottom.

As these internal motions of fluids can only be discovered by mixing with them bodies of the same specific gravity with themselves, and as there is hardly any substance of the same specific gravity with water which is not soluble in it, Count Rumford had recourse to the following ingenious method of ascertaining whether that fluid also followed the same law. The specific gravity of water is increased considerably by dissolving any salt in it; he added, therefore, potash to water till its specific gravity was exactly equal to that of amber, a substance but very little heavier than pure water. A number of small pieces of amber were then mixed with this solution, and the whole put into a glass globe with a long neck, which, on being heated and exposed to cool, exhibited exactly the same phenomena with the other fluids. A change of temperature, amounting only to a very few degrees, was sufficient to set the currents a-flowing; and a motion might at any time be produced by applying a hot or a cold body to any part of the vessel. When a hot body was applied, that part of the fluid nearest it ascended; but it descended on the application of a cold body.

260 Proofs of the non-conducting power of water,

If caloric pass through water only by the internal motion of its particles, as this experiment seems to prove, it is evident that every thing which embarrasses these motions must retard its transmission: and accordingly Count Rumford found this to be the case. He took a large linseed-oil thermometer with a copper bulb and glass tube: the bulb was placed exactly in the centre of a brass cylinder, so that there was a void space between them all around 0,25175 of an inch thick. The thermometer was kept in its place by means of four wooden pins projecting from the sides and bottom of the cylinder, and by the tube of it passing through the cork stopper of the cylinder. This cylinder was filled with pure water, then held in melting snow till the thermometer fell to 32°, and immediately plunged into a vessel of boiling water. The thermometer rose from 32° to 200° in 597″. It is obvious that all the caloric which served to raise the thermometer must have made its way through the water in the cylinder. The experiment was repeated exactly in the same manner, but the water in the cylinder, which amounted to 2276 gr. had 192 gr. of starch boiled in it, which rendered it much less fluid. The thermometer now took 1109″ to rise from 32° to 200°. The same experiment was again repeated with the same quantity of pure water, having 192 gr. of eiderdown mixed with it, which would merely tend to embarrass the motion of the particles. A quantity of stewed apples were also in another experiment put into the cylinder. The following tables exhibit the result of all these experiments.

Time the Caloric was in passing into the Thermometer.

Temperature.	Through the Water and Starch	Thro' the Water and Eiderdown.	Through stewed Apples	Through pure Water
Therm. rose from 32° to 200° in	Seconds. 1109	Seconds, 949	Seconds. $1096\frac{1}{2}$	Seconds. 597
Therm. rose 80°, *viz* from 80° to 160°, in	341	269	335	172

Time the Caloric was in passing out of the Thermometer.

Temperature.	Through the Water and Starch.	Thro' the Water and Eiderdown.	Through stewed Apples.	Through pure Water.
Therm. fell from 200° to 40° in	Seconds. 1548	Seconds. 1541	Seconds. $1749\frac{1}{2}$	Seconds. 1032
Therm. fell 80°, *viz.* from 160° to 80°, in	468	460	520	277

Now, neither the starch nor the eiderdown could produce any alteration in the water except impeding its internal motions: consequently whatever impedes these motions diminishes the conducting power of water. But this could not happen unless every individual particle actually went from the cylinder to the thermometer.

Only one proof more was wanting to remove every doubt; and this proof also Count Rumford has given us. If water be a non-conductor, it is evident that no caloric can pass downwards when the heat is applied to the surface; for as the particles of water become specifically lighter by being heated, they cannot sink to the bottom. Accordingly Count Rumford found, that water might be made actually to boil near the top of a glass tube, while that at the bottom was not sensibly warmed. Owing to the law already mentioned, indeed, that water, after being cooled down to 40°, expands instead of contracting when its temperature is lowered, a mass of water may be raised to 40° by applying the heat to its upper surface; because water at 40° is heavier than at any degree below it, and will therefore sink to the bottom; but its temperature cannot be raised any higher. This Count Rumford proved, by shewing that water of the temperature of 40°, placed above ice, will

Caloric.

melt as much of it in the fame time as water at any higher temperature whatever, even boiling hot.

Into a cylindrical glafs jar 4,7 inches in diameter and 13,8 inches high, he put 43,87 cubic inches, or 1 lb. 11$\frac{1}{7}$ oz. troy of water, and placing the jar in a freezing mixture compofed of pounded ice and common fea falt, he froze the water into one compact mafs. The jar was then put into a mixture of pounded ice and pure water, reaching exactly to the top of the ice in it, and fuffered to remain there four hours, that the ice might come to the temperature of 32°; then boiling water was cautioufly poured on it, and the jar ftill allowed to ftand in the ice and water. He foon found that a confiderable quantity of ice was melted at the very beginning of the experiment, owing to the agitation into which the water was thrown by the act of pouring it into the veffel. To prevent this as much as poffible, he covered the ice with a fmall quantity of ice cold water, upon which he placed a flat fhallow difh of light wood 4$\frac{1}{2}$ inches in diameter, and about one-fourth of an inch thick at the bottom. This veffel was perforated by feveral hundred very fmall holes. The hot water was poured into this difh through a long wooden tube, the bottom of which was ftopped up, and the water made to iffue through fmall holes in the fide at the lower end. As this difh always floated on the furface of the water, and as the fluid paffing through it by a number of fmall holes was not projected with force, it is evident that a confiderable part of thefe violent motions was prevented. The following is the refult of three experiments made in this manner.

Number of Experiments.	Time the hot Water was on the Ice.	Temperature of the hot Water one inch below its furface.		Quantity of Ice melted.
		At the beginning.	At the end	
	Minutes.			Grains.
1	10	192°	182°	580
2	30	190°	165°	914
3	180	190°	95°	3200

From thefe experiments he determined the quantity of ice melted in the act of pouring the water into the jar, fuppofing equal quantities to be melted in equal times. If 3200 grains were melted in 180′, fubtracting 580, the quantity melted in 10′, there remains 2620 gr. for the quantity melted in 170′, in every ten of which 154 gr. muft have been melted; for 170 : 10 : : 2620 : 154 nearly. Subtracting 154 from 580, the quantity melted in the firft ten minutes, there remains 426 gr. for the quantity melted in pouring the water into the jar. From the fecond experiment it follows, by a fimilar calculation, that 159 gr. were melted every 10 minutes; which fhows that the motions produced by pouring in the water had not ceafed in 30 minutes. It will be nearer the truth, therefore, if we endeavour to difcover the quantity melted every ten minutes by comparing the fecond and third experiments. By a fimilar calculation to the above, it comes out to be 152 gr. The following table exhibits the refults of feveral experiments, made exactly in the fame manner, but with water at a much lower temperature.

Number of Experiments.	Temper. of the Water in the Jar one inch below its furface.		Temper. of the Air.	Time the Water remained on the Ice.	Quantity of Ice melted.
	Before.	After.			
1	41°	40°	41°	10′	203 gr.
2	41	40	41	10	220
3	41	40	41	10	237
4	41	40	41	10	228
5	41	38	41	30	617
6	41	38	41	30	585

From thefe experiments it appears that the quantity of ice melted in 10′ by water at the temperature of 41° was 222 gr. while boiling water melted only 152 gr. in the fame time. To difcover whether any of this was melted in the act of pouring in the water; from a mean of the two laft experiments it appears, that 601 grains were melted in 30′: if from this 222 grains (the mean of the four firft) be deducted, there will remain 379 grains for the quantity melted in 20′, confequently 189$\frac{1}{2}$ grains is what muft have been melted in the ordinary courfe of the procefs; a quantity confiderably above 152 grains. Therefore water at 41° melts more ice in the fame time than boiling water. This Count Rumford accounts for by fuppofing, that in the hot water the defcending current from the top of the veffel, and afcending one from the ice, meeting one another in that part of the veffel where the temperature is 40°, retard each others motions, and thus prevent the melting procefs from going on fo rapidly as when there is no defcending current. And he found accordingly, that when the cooling of the water above was retarded by wrapping up the jar in a warm covering, the ice melted fafter; and when the cooling above was accelerated, it melted flower. It is evident, that in the one cafe the velocity of the defcending current was diminifhed, in the other accelerated.

Thus it has been completely proved, that water is a non-conductor of caloric. But is this the cafe alfo with other liquids? 261

Oil and mercury;

When water was frozen in a glafs jar by means of a freezing mixture, Count Rumford obferved, that the ice firft began to be formed at the fides, and gradually increafed in thicknefs; and that the water on the axis of the veffel, which retained its fluidity longeft, being compreffed by the expanfion of the ice, was forced upwards, and when completely frozen formed a pointed projection or nipple, which was fometimes half an inch higher than the reft of the ice. Upon ice frozen in this manner, he poured olive oil, previoufly cooled down to 32°, till it ftood at the height of three inches above the ice.

Caloric. ice. The veſſel was ſurrounded as high as the ice with a mixture of pounded ice and water. A ſolid cylinder of wrought iron, $1\frac{1}{4}$th inch in diameter and 12 inches long, provided with a hollow cylindrical ſheath of thick paper, was heated to the temperature of 210° in boiling water; and being ſuddenly introduced into its ſheath, was ſuſpended from the ceiling of the room, and very gradually let down into the oil, until the middle of the flat ſurface of the hot iron, which was directly above the point of conical projection of the ice, was diſtant from it only $\frac{2}{10}$ths of an inch. The end of the ſheath deſcended $\frac{1}{10}$th of an inch lower than the end of the hot metallic cylinder. Now it is evident, that if olive oil was a conductor, caloric would paſs down through it from the iron and melt the ice. None of the ice, however, was melted; and when mercury was ſubſtituted for oil, the reſult was juſt the ſame;* conſequently it follows, that neither oil nor mercury is a conductor of heat. We may conclude, therefore, with Count Rumford, that this is the caſe with liquids in general.

* *Rumford, Eſſay* vii. Part ii. chap. I.

262 Air;

Sennebier obſerved ſome time ago, that air was a very bad conductor of caloric, and that it reſiſted every change of temperature very much.* But it was reſerved for Count Rumford to prove, that it conducted it at all only by the internal motions of its particles, or that it was in fact a *non-conductor*, exactly in the ſenſe that liquids are non-conductors.* This he eſtabliſhed by ſhewing, that whatever tended to obſtruct or impede the internal motions of its particles, diminiſhed its conducting power. By mixing with a quantity of air $\frac{1}{10}$th of its bulk of eiderdown, he diminiſhed its conducting power more than one half. The warmth of furs and feathers and ſilk depends on a very ſtrong attraction between them and air, which is therefore confined in their interſtices, and thus the caloric prevented from paſſing out of the body. A *ſingle* metallic cover to a boiler in a ſhort time grew ſo hot that it could not be touched, while another of exactly the ſame form, but *double*, with a quantity of air confined in the middle, ſcarcely felt hot ‡. There can be no doubt that all the gaſes are alſo non-conductors; and Count Rumford has proved the ſame thing of ſteam by the following experiment, which we ſhall relate in his own words †:

* *Journ. de Phyſ.* 1788.

263 And ſteam.

" A large globular bottle being provided, of very thin and very tranſparent glaſs, with a narrow neck, and its bottom drawn inward ſo as to form a hollow hemiſphere about 6 inches in diameter; this bottle, which was about 8 inches in diameter externally, being filled with cold water, was placed in a ſhallow diſh, or rather plate, about 10 inches in diameter, with a flat bottom formed of very thin ſheet braſs, and raiſed upon a tripod, and which contained a ſmall quantity (about $\frac{2}{10}$ths of an inch in depth) of water; a ſpirit lamp being then placed under the middle of this plate, in a very few minutes the water in the plate began to boil, and the hollow formed by the bottom of the bottle was filled with clouds of ſteam, which, after circulating in it with ſurpriſing rapidity 4 or 5 minutes, and after forcing out a good deal of air from under the bottle, began gradually to clear up. At the end of 8 or 10 minutes (when, as I ſuppoſed, the air remaining with the ſteam in the hollow cavity formed by the bottom of the bottle had acquired nearly the ſame temperature as that of the ſteam) theſe clouds totally diſappeared; and though the water continued to boil with the utmoſt violence, the contents of this hollow cavity became ſo perfectly inviſible, and ſo little appearance was there of ſteam, that, had it not been for the ſtreams of water which were continually running down its ſides, I ſhould almoſt have been tempted to doubt whether any ſteam was actually generated.

" Upon lifting up for an inſtant one ſide of the bottle, and letting in a ſmaller quantity of cold air, the clouds inſtantly returned, and continued circulating ſeveral minutes with great rapidity, and then gradually diſappeared as before. This experiment was repeated ſeveral times, and always with the ſame reſult; the ſteam always becoming viſible when cold air was mixed with it, and afterwards recovering its tranſparency when, part of this air being expelled, that which remained had acquired the temperature of the ſteam.

" Finding that cold air introduced under the bottle cauſed the ſteam to be partially condenſed, and clouds to be formed, I was deſirous of ſeeing what viſible effects would be produced by introducing a cold ſolid body under the bottle. I imagined that if ſteam was a conductor of heat, ſome part of the heat in the ſteam paſſing out of it into the cold body, clouds would of courſe be formed; but I thought if ſteam was a non-conductor of heat, that is to ſay, if one particle of ſteam could not communicate any part of its heat to its neighbouring particles, in that caſe, as the cold body could only affect the particles of ſteam actually in contact with it, no cloud would appear, and the reſult of the experiment ſhewed that ſteam is in fact a non-conductor of heat; for, notwithſtanding the cold body uſed in this experiment was very large and very cold, being a ſolid lump of ice nearly as large as an hen's egg, placed in the middle of the hollow cavity under the bottle, upon a ſmall tripod or ſtand made of iron wire; yet as ſoon as the clouds which were formed in conſequence of the unavoidable introduction of cold air in lifting up the bottle to introduce the ice, were diſſipated, which ſoon happened, the ſteam became ſo perfectly tranſparent and inviſible, that not the ſmalleſt appearance of cloudineſs was to be ſeen anywhere, not even about the ice, which, as it went on to melt, appeared as clear and as tranſparent as a piece of the fineſt rock cryſtal." Thus, then, it appears, that all elaſtic fluids are non-conductors as well as liquids.

6. If equal quantities of water and of mercury be placed at the ſame diſtance from a fire, the mercury will 264
become hot much ſooner than the water. After a ſufficient interval, however both of them acquire the ſame temperature. Now caloric flows into all bodies while they continue of a lower temperature than thoſe around them, and it flows with equal rapidity into all bodies of the ſame conducting powers, as is the caſe with theſe two fluids: But if equal quantities of caloric were conſtantly flowing into the mercury and the water, and yet the water took a longer time to become hot than the mercury, it muſt require a greater quantity of caloric to raiſe water to a given temperature than it does to raiſe mercury. Bodies that require a greater quantity of caloric to raiſe them to a particular temperature than other bodies require, are ſaid to have a greater *capacity* for caloric. That the capacity for caloric is different in different bodies, was firſt obſerved by Dr Black.

Specific caloric of bodies, what.

Dr

Caloric.

Dr Irvine afterwards investigated the subject, and Dr Crawford published a great number of experiments on it in his *Treatise on Heat*. Professor Wilcke of Stockholm, also discovered the same property of bodies. He called the quantity of caloric necessary to raise the temperature of substances a given number of degrees, their *specific caloric*; a term which we shall also employ, because the phrase *capacity for caloric* is liable to a great deal of ambiguity, and has introduced confusion into this subject (F). If two substances of unequal temperatures, as water at 100° and alcohol at 50°, be mixed together, the mixture will be of a temperature different both from that of the water and the alcohol, the water will become colder and the alcohol hotter: the water will give out caloric to the alcohol till both are reduced to the same temperature. Now if it requires just as much caloric to raise alcohol a certain number of degrees as it does to raise water the same number, that is, if these two fluids are of the same specific caloric, it is evident that the temperature of the mixture will be just 75°; for as soon as the water has given out 25° of caloric, the alcohol has acquired 25°, consequently both will be reduced to the same temperature, and will remain stationary; but if the specific caloric of the water be greater than that of the alcohol, the temperature of the mixture will be higher than 75°: for 25° of caloric in that case would raise alcohol more than 25°. If the specific caloric of water be so much greater than that of alcohol, that what raises water 20° will raise alcohol 30°; then the temperature after mixture will be 80°, because, when the water has given out 20°, the alcohol will have risen 30°, and of course both will be of the same temperature. On the contrary, if the specific caloric of alcohol were greater than that of water, the temperature of the mixture would be under 75°. If the same quantity of caloric that raised alcohol 20°, raised water 30°, then the temperature of the mixture would be 70°. Thus the ratios of the specific caloric of bodies may be discovered by mixing them together at different temperatures (18).

265
Experiments on specific caloric by Wilcke,

The first set of experiments on this subject, in point of time, were probably those of Mr Wilcke. They were first published in the Stockholm Transactions for 1781, but had been made long before. The manner in which they were conducted is exceedingly ingenious, and they furnish us with the specific caloric of many of the metals. The metal on which the experiment was to be made was first weighed accurately (generally one pound was taken), and then being suspended by a thread, was plunged into a large vessel of tinplate, filled with boiling water, and kept there till it acquired a certain temperature, which was ascertained by a thermometer. Into another small box of tinplate exactly as much water at 32° was put as equalled the weight of the metal. Into this vessel the metal was plunged, and suspended in it so as not to touch its sides or bottom; and the degree of heat, the moment the metal and water were reduced to the same temperature, was marked by a very accurate thermometer. He then calculated what the temperature would have been if a quantity of water equal in *weight* to the metal, and of the same temperature with it, had been added to the ice-cold water instead of the metal.

Let M be a quantity of water at the temperature C, m another quantity at the temperature c, and let their common temperature after mixture be x; according to a rule demonstrated long ago by Richman, $x = \frac{MC + mc}{M + m}$. In the present case the quantities of water are equal, therefore M and m are each $= 1$; C, the temperature of the ice-cold water $= 32$: therefore $\frac{MC + mc}{M + m} = \frac{32 + c}{2}$. Now c is the temperature of the metal. Therefore if 32 be added to the temperature of the metal, and the whole be divided by 2, the quotient will express the temperature of the mixture, if an equal weight of water with the metal, and of the same temperature with it, had been added to the ice-cold water instead of the metal.

He then calculated what the temperature of the mixture would have been if, instead of the metal, a quantity of water of the same temperature with it, and equal to the metal in *bulk*, had been added to the ice-cold water. As the weights of the ice-cold water and the metal are equal, their volumes are inversely as their specific gravities. Therefore the volume of ice-cold water is to a quantity of hot water equal in volume to the metal, as the specific gravity of the metal to that of the water. Let M = volume of cold water, m = volume of hot water, g = specific gravity of the metal, 1 = specific gravity of water; then $m : M :: 1 : g$; hence

$m =$

(F) The term *specific caloric* has been used in a different sense by Seguin. He used it for the *whole caloric* which a body contains.

(18) This appears to me to be by no means a just method of judging of the specific caloric of bodies even when it can be practised. The very foundation is error. It is considering the properties of the constituent principles by that of the compound. This never can be done with certainty and in this particular case facts prove it to be peculiarly erroneous. According to the principles of this *test*, if any two substances were mixed together at the *same* temperature the compound would be of the same temperature as each of them would have a sufficiency of caloric to maintain them just at that temperature. Let us combine sulphuric acid and water, and water and muriat of ammoniac, at equal temperatures, and observe what takes place. In the first case the temperature is much encreased and in the other decreased. Why do these changes take place? Because the compound is not of a mean *specific caloric* to the constituent principles. No inference from its temperature therefore can be drawn as to the *specific caloric* of those principles. T. P. S.

Caloric. $m = \frac{M}{g}$ = (M being made = 1) $\frac{1}{g}$. Subſtituting this value of m in the formula, $\frac{MC + mc}{M + m} = x$, in which M = 1 and C = 32, x will be = $\frac{32\,g + c}{g + 1}$. Therefore if the ſpecific gravity of the metal be multiplied by 32, and the temperature of the metal be added, and the ſum be divided by the ſpecific gravity of the metal + 1, the quotient will expreſs the temperature to which the ice-cold water would be raiſed by adding to it a volume of water equal to that of the metal, and of the ſame temperature with it.

He then calculated how much water at the temperature of the metal it would take to raiſe the ice-cold water the ſame number of degrees which the metal had raiſed it. Let the temperature to which the metal had raiſed the ice-cold water be = N, if in the formula $\frac{MC + mc}{M + m} = x$, x be made = N, M = 1, C = 32, m will be = $\frac{N - 32}{c - N}$. Therefore if from the temperature to which the ice-cold water was raiſed by the metal 32 be ſubtracted, and if from the temperature of the metal be ſubtracted the temperature to which it raiſed the water and the firſt remainder be divided by the laſt, the quotient will expreſs the quantity of water of the temperature of the metal which would have raiſed the ice-cold water the ſame number of degrees that the metal did.
